For the ε-based Reynolds stress models, by default ANSYS Fluent uses the explicit setting of boundary conditions for the Reynolds stresses near the walls, with the values computed with Equation 4.238 (in the Theory Guide). The turbulent kinetic energy, k, is calculated by solving the k equation obtained by summing Equation 4.204 (in the Theory Guide) for normal stresses. To disable this option and use the wall boundary conditions given in Equation 4.239 (in the Theory Guide), turn off the **Wall BC from k Equation** under the **Reynolds-Stress Options** in the **Viscous Model** dialog box.

Important

This option will not appear unless you have enabled the **Reynolds Stress** model.

11.16.18. Quadratic Pressure-Strain Model

To use the quadratic pressure-strain model described in Quadratic Pressure-Strain Model (in the Theory Guide), enable the **Quadratic Pressure-Strain Model** option under **Reynolds-Stress Options** in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Viscous Model Dialog Box (p. 2176). (This option will not appear unless you have enabled the RSM.) The following options are not available when the **Quadratic Pressure-Strain Model** is enabled:

- **Wall Reflection Effects** under **Reynolds-Stress Options**
- **Enhanced Wall Treatment** under **Near-Wall Treatment**

11.16.19. Stress-Omega and Stress-BSL Models

To use the Stress-Omega model (described in Stress-Omega Model) or the Stress-BSL model (described in Stress-BSL Model), select **Stress-Omega** or **Stress-BSL**, respectively, from the **Reynolds-Stress Model** list in the Viscous Model Dialog Box (p. 2176). (These options will not appear unless you have enabled the RSM.) The following options are not available when the **Stress-Omega** or the **Stress-BSL** model is selected:

- **Wall BC from k Equation** under **Reynolds-Stress Options**
- **Wall Reflection Effects** under **Reynolds-Stress Options**
- **Standard Wall Functions** under **Near-Wall Treatment**
- **Scalable Wall Functions** under **Near-Wall Treatment**
- **Non-Equilibrium Wall Functions** under **Near-Wall Treatment**
- **Enhanced Wall Treatment** under **Near-Wall Treatment**

Instead, the following options are available:

- **Low-Re Corrections** under **k-omega Options** (for **Stress-Omega** only)
- **Shear Flow Corrections** under **k-omega Options** (for **Stress-Omega** only)
- **Scale-Adaptive Simulation (SAS)** under **Scale-Resolving Simulation Options**

11.16.20. Subgrid-Scale Model

If you have selected the **Large Eddy Simulation** model, you will be able to choose one of the subgrid-scale models described in Subgrid-Scale Models (in the Theory Guide). You can choose from the **Smagorinsky-Lilly**, **WALE**, **WMLES**, **WMLES S-Omega**, or **Kinetic-Energy Transport** subgrid-scale models. Note that **Dynamic Stress** is an option available with the **Smagorinsky-Lilly** model (and when it is enabled, this model is referred to as the "dynamic Smagorinsky" model), while the **Kinetic-Energy Transport** model is always run as a dynamic model. The **Dynamic Fvar** option is available for all of the subgrid-scale models when **Non-Premixed Combustion** or **Partially Premixed Combustion** is selected in the Species Model Dialog Box (p. 2216).

Important

These options will not appear unless you have enabled the LES model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.16.21. Customizing the Turbulent Viscosity

If you are using the Spalart-Allmaras, k-ε, k-ω, DES, or LES models, a UDF can be used to customize the turbulent viscosity. This option will enable you to modify μ_t in the case of the Spalart-Allmaras, k-ε, and k-ω models, and incorporate completely new subgrid models in the case of the LES model. SBES with BSL / SST allows the usage of a UDF in order to provide a custom formulation for μ_t in the RANS region, but not for the subgrid model in the LES region. More information about UDFs can be found in the Fluent Customization Manual.

In the Viscous Model Dialog Box (p. 2176), under **User-Defined Functions**, select the appropriate user-defined function in the **Turbulent Viscosity** drop-down list. For the LES model, select the appropriate UDF in the **Subgrid-Scale Turbulent Viscosity** drop-down list.

11.16.22. Customizing the Turbulent Prandtl and Schmidt Numbers

You can use UDFs to customize the turbulent Prandtl and Schmidt numbers. For the standard and realizable k-ε models and the standard k-ω model, your UDF can calculate the TKE Prandtl number (σ_k) and either the TDR or SDR Prandtl number (σ_ε or σ_ω), depending on whether you are using the k-ε or k-ω model. All turbulence models allow you to use UDFs for the turbulent Prandtl number at the wall (Pr_t in Equation 4.319 in the Theory Guide), and all turbulent models except for the RNG k-ε model allow you to use UDFs for the turbulent Prandtl number for energy (Pr_t in, for example, Equation 4.63 or Equation 4.229 in the Theory Guide), as well as the turbulent Schmidt number (Sc_t, in Equation 7.3 in the Theory Guide) if species transport has been enabled. Note that UDFs cannot be used for the turbulent Prandtl number for energy or the turbulent Schmidt number if you have enabled **Dynamic Energy Flux** or **Dynamic Scalar Flux**, respectively, as part of the LES model. More information about UDFs can be found in the Fluent Customization Manual.

In the Viscous Model Dialog Box (p. 2176), under **User-Defined Functions**, select the appropriate UDF from the drop-down lists in the **Prandtl Numbers** or **Prandtl and Schmidt Numbers** group box. The options will depend on the turbulence model you have selected (as noted previously), and include: **TKE Prandtl Number**, **TDR Prandtl Number**, **SDR Prandtl Number**, **Energy Prandtl Number**, **Wall Prandtl Number**, and **Turbulent Schmidt Number**. Note that the availability of these drop-down lists can be affected by your settings for the energy equation and the multiphase and combustion models.

11.16.23. Modeling Turbulence with Non-Newtonian Fluids

If the turbulent flow involves non-Newtonian fluids, you can use the `define/models/viscous/turbulence-expert/turb-non-newtonian?` text command to enable the selection of non-Newtonian options for the material viscosity. See Viscosity for Non-Newtonian Fluids (p. 492) for details about these options.

11.16.24. Including Scale-Adaptive Simulation with ω-Based URANS Models

You have the option of including Scale-Adaptive Simulation (SAS) with most ω-based URANS models. For details about SAS and how to include it, see Scale-Adaptive Simulation (SAS) (p. 758) and Setting Up Scale-Adaptive Simulation (SAS) Modeling (p. 781), respectively.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.16.25. Including Detached Eddy Simulation with the Transition SST Model

You have the option of including Detached Eddy Simulation (DES) with the Transition SST model. For details about DES and how to include it, see Detached Eddy Simulation (DES) (p. 758) and Setting Up DES with the Transition SST Model (p. 789), respectively.

11.16.26. Including the SDES or SBES Model with BSL, SST, and Transition SST Models

To enable a hybrid RANS-LES model with an improved shielding function compared to DDES / IDDES, you can enable the **Stress Blending (SBES) / Shielded DES** option in the **Scale-Resolving Simulation Options** group box of the **Viscous Model** dialog box. This option is available for 3D transient cases when you have selected one of the following models (see Figure 11.24: The Viscous Model Dialog Box with the SBES Options (p. 806)):

- Baseline (BSL) k-ω model
- Shear-Stress Transport (SST) k-ω model
- Transition SST model

You can then select one of the following from the **Hybrid Model** list:

- **SDES** to apply only a shielding function (Shielded Detached Eddy Simulation (SDES) in the *Fluent Theory Guide*)
- **SBES** to apply a shielding function with stress blending (Stress-Blended Eddy Simulation (SBES) in the *Fluent Theory Guide*)
- **SBES with User-Defined Function** to define your own blending function zonally for cases where the division between RANS and LES is clear from the geometry and the flow physics (`DEFINE_SBES_BF` in the *Fluent Customization Manual*)

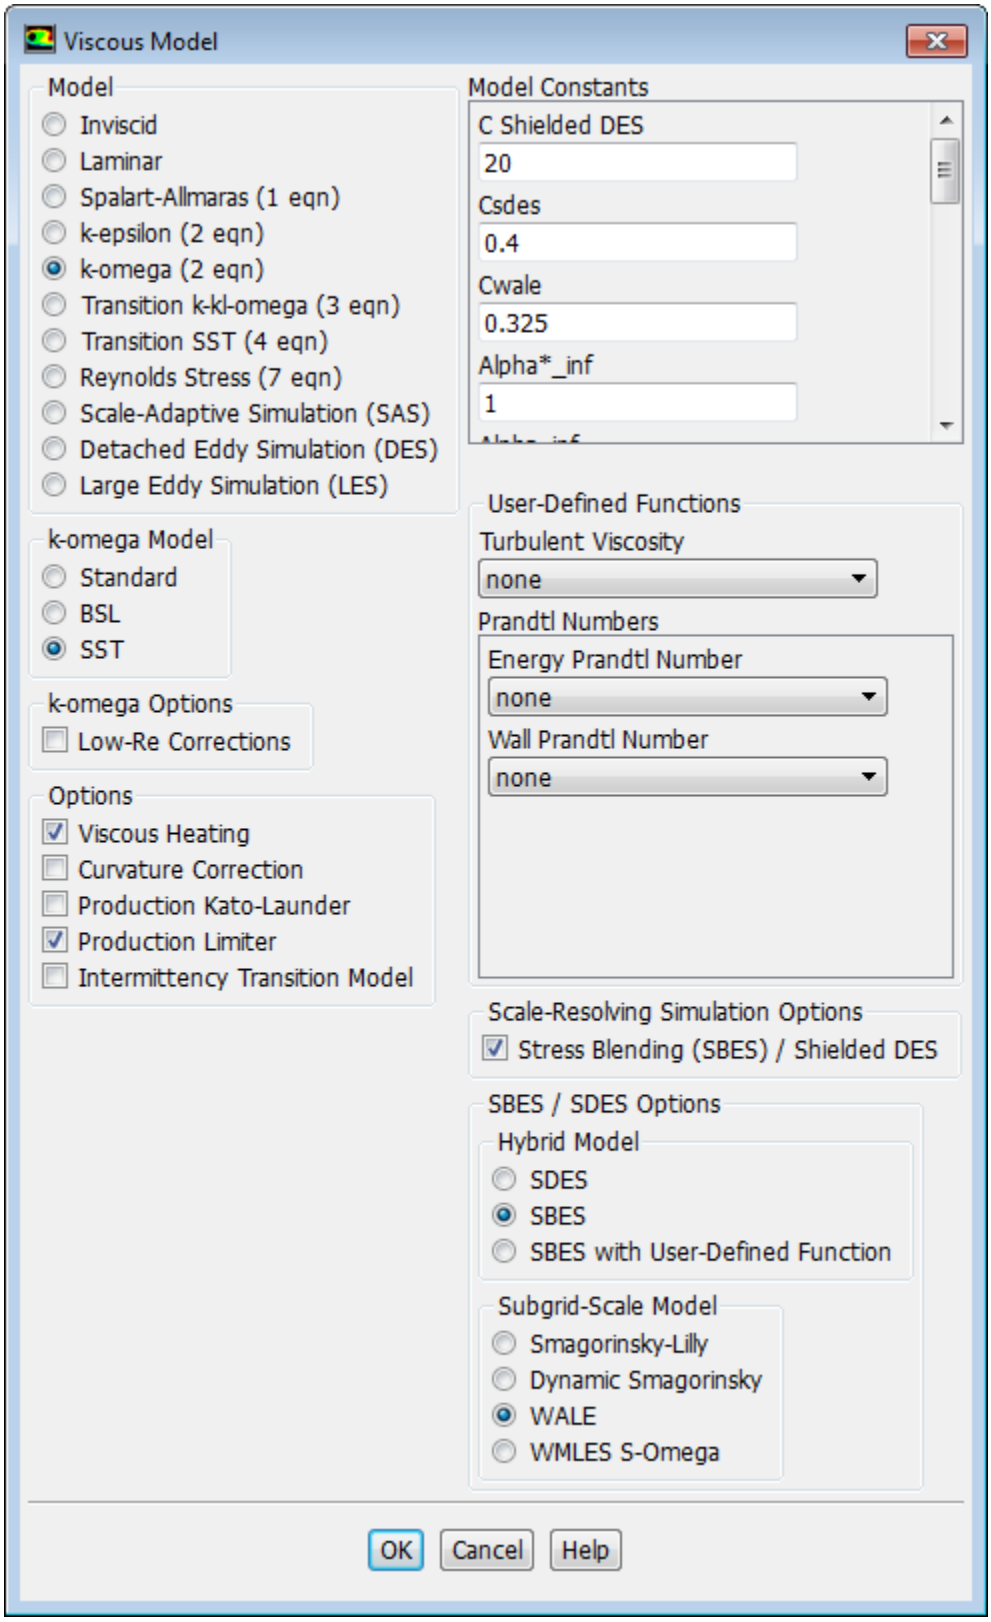
If you select **SBES** or **SBES with User-Defined Function** for the **Hybrid Model**, you can also select one of the following subgrid-scale (LES) models:

- **Smagorinsky-Lilly** model
- **Dynamic Smagorinsky**-Lilly model
- Wall-Adapting Local Eddy-Viscosity (**WALE**) model
- Algebraic Wall-Modeled LES S-Ω (**WMLES S-Omega**) model

The **WALE** model is recommended, as it provides the lowest eddy viscosity in 2D flow regions and thereby allows the flow to quickly develop 3D turbulence structures in separating shear layers. The combination of SBES with the **WMLES S-Omega** formulation is likely not a useful combination, as the SBES-WALE model combination can by itself act in a WMLES mode.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 11.24: The Viscous Model Dialog Box with the SBES Options



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.16.27. Shielding Functions for the BSL / SST / Transition SST Detached Eddy Simulation Model

For the DES model with the BSL k-ω model, SST k-ω model, or the Transition SST model, the shielding (or blending) functions F1 and F2 are defined in Equation 4.107 and Equation 4.118 in the Theory Guide, respectively. Note that the F2 function is more conservative than the F1 function. In addition, the shielding functions DDES (Delayed DES) and IDDES (Improved Delayed DES), are described in DES with the BSL or SST k-ω Model and Improved Delayed Detached Eddy Simulation (IDDES) in the Theory Guide. DDES is recommended and is used as the default.

11.17. Defining Turbulence Boundary Conditions

For additional information, see the following sections:

11.17.1. Wall Roughness Effects
11.17.2. The Spalart-Allmaras Model
11.17.3. k-ε Models and k-ω Models
11.17.4. Reynolds Stress Model
11.17.5. Large Eddy Simulation Model

11.17.1. Wall Roughness Effects

You may want to include the effects of the wall roughness on selected wall boundaries as part of your turbulent simulation. In such cases, you can specify the roughness parameters (roughness height and roughness constant) in the dialog boxes of the corresponding wall boundaries (see Setting the Roughness Parameters (p. 368)).

Note

Rough walls cannot be used together with the following model combinations:

- an ε-equation model with enhanced wall treatment or the Menter-Lechner near-wall treatment

  Note that the following are the relevant ε-equation models:

  – all of the k-ε models (that is, standard, RNG, and realizable)

  – the Reynolds stress model with the **Linear Pressure-Strain** model selected

  – the detached eddy simulation (DES) model with the **Realizable k-epsilon** option selected

- the Reynolds stress model with the **Stress-Omega** or **Stress-BSL** model selected
- the transition k-kl-ω model
- the large eddy simulation (LES) model

11.17.2. The Spalart-Allmaras Model

When you are modeling turbulent flows in ANSYS Fluent using the Spalart-Allmaras model, you must provide the boundary conditions for $\tilde{\nu}$ in addition to other mean solution variables. The boundary conditions for $\tilde{\nu}$ at the walls are internally taken care of by ANSYS Fluent, which obviates the need for

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

your inputs. The boundary condition input for $\tilde{\nu}$, which you must enter in ANSYS Fluent, is the one at inlet boundaries (for example, velocity inlets, pressure inlets). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

11.17.3. k-ε Models and k-ω Models

When you are modeling turbulent flows in ANSYS Fluent using one of the k-ε models or one of the k-ω models, you must provide the boundary conditions for k and ε (or k and ω) in addition to other mean solution variables. The boundary conditions for k and ε (or k and ω) at the walls are internally taken care of by ANSYS Fluent, which obviates the need for your inputs. The boundary condition inputs for k and ε (or k and ω), which you must enter in ANSYS Fluent, are the ones at inlet boundaries (for example, velocity inlets, pressure inlets). In many situations, it is important to specify correct or realistic boundary conditions at the inlets, because the inlet turbulence can significantly affect the downstream flow.

See Determining Turbulence Parameters (p. 303) for details about specifying the boundary conditions for k and ε (or k and ω) at the inlets.

Additionally, you can control whether or not to set the turbulent viscosity to zero within a laminar zone. If the fluid zone in question is laminar, the text command `define/ boundary-conditions/fluid` will contain an option called `Set Turbulent Viscosity to zero within laminar zone?`. By setting this option to `yes`, ANSYS Fluent will set both the production term in the turbulence transport equation and μ_t to zero. In contrast, when the **Laminar Zone** option is enabled in a **Fluid** cell zone condition dialog box, only the production term is set to zero. See Specifying a Laminar Zone (p. 255) for details about laminar zones.

Important

Note that the laminar zone feature is also available for the Spalart-Allmaras and Reynolds stress models.

11.17.4. Reynolds Stress Model

The specification of turbulent boundary conditions for the RSM is the same as for the other turbulence models for all boundaries except at boundaries where flow enters the domain. Additional input methods are available for these boundaries and are described here.

When you choose to use the RSM, the default inlet boundary condition inputs required are identical to those required when the k-ε model is active. You can input the turbulence quantities using any of the turbulence specification methods described in Determining Turbulence Parameters (p. 303). ANSYS Fluent then uses the specified turbulence quantities to derive the Reynolds stresses at the inlet from the assumption of isotropy of turbulence:

$$\overline{u_i'^2} = \frac{2}{3}k \quad (i=1,2,3) \tag{11.6}$$

$$\overline{u'_i u'_j} = 0.0 \tag{11.7}$$

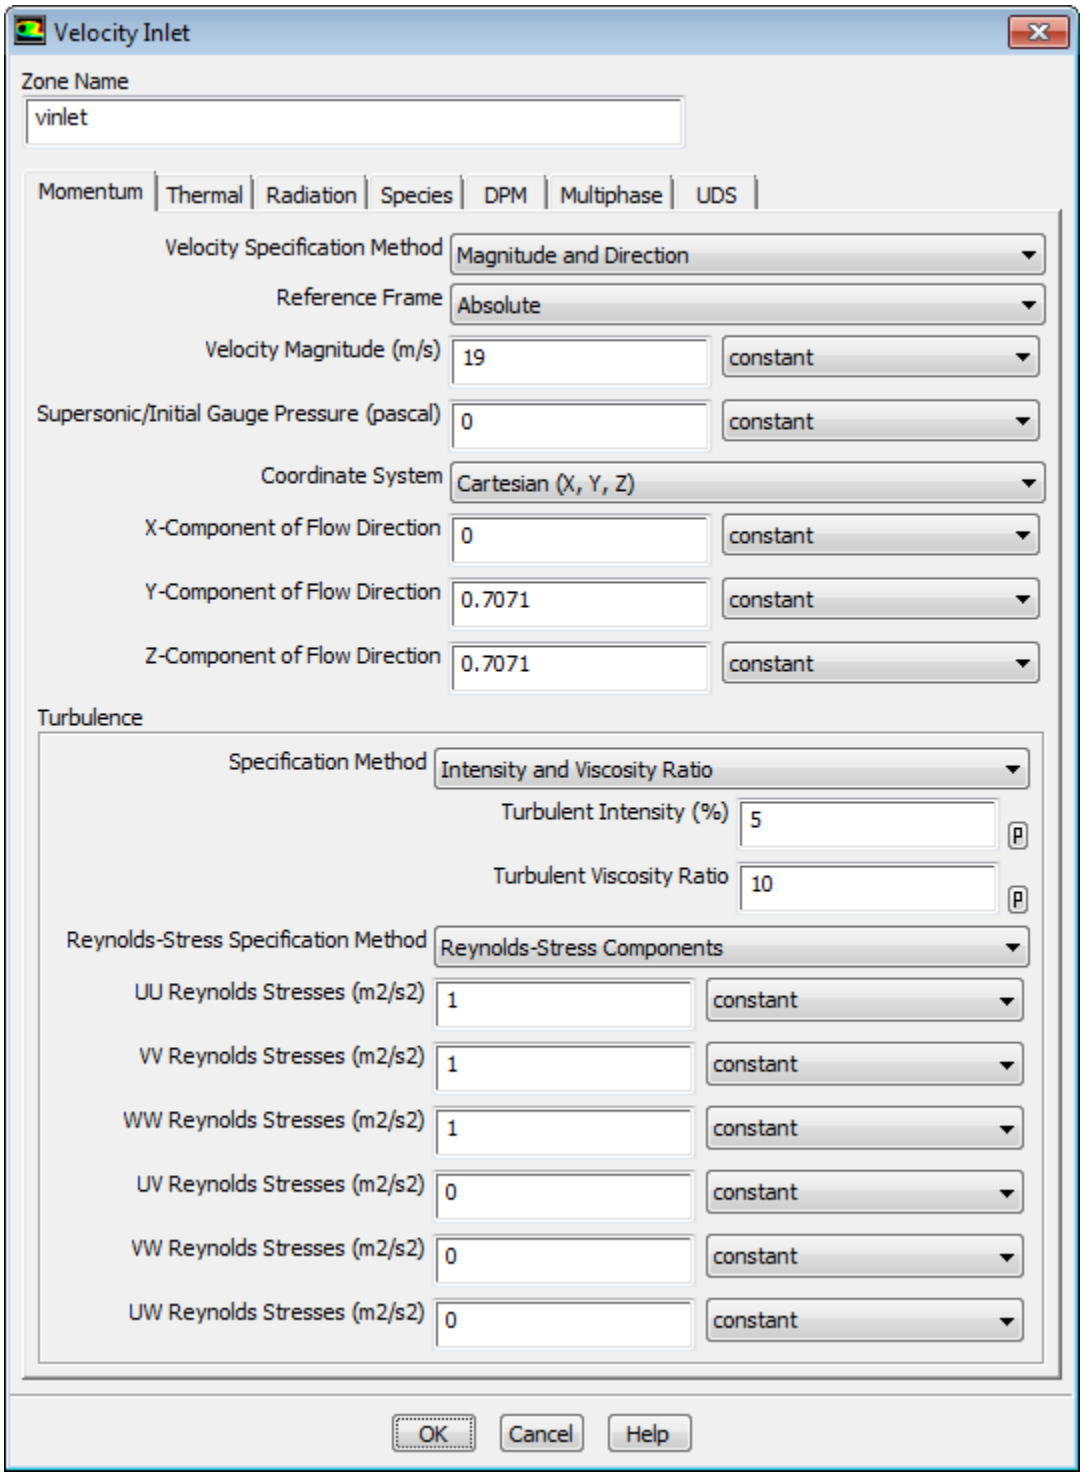
where $\overline{u_i'^2}$ is the normal Reynolds stress component in each direction. The boundary condition for ε is determined in the same manner as for the k-ε turbulence models (see Determining Turbulence Parameters (p. 303)). To use this method, you will select **K or Turbulent Intensity** as the **Reynolds-Stress Specification Method** in the appropriate boundary condition dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alternately, you can directly specify the Reynolds stresses by selecting the **Reynolds-Stress Components** as the **Reynolds-Stress Specification Method** in the boundary condition dialog box. When this option is selected, you should input the Reynolds stresses directly.

You can set the Reynolds stresses by using constant values, profile functions of coordinates (see Profiles (p. 435)), or user-defined functions (in the Fluent Customization Manual).

Figure 11.25: Specifying Inlet Boundary Conditions for the Reynolds Stresses



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.17.5. Large Eddy Simulation Model

It is possible to specify the magnitude of random fluctuations of the velocity components at an inlet only if the velocity inlet boundary condition is selected. In this case, you must specify a **Turbulence Intensity** that determines the magnitude of the random perturbations on individual mean velocity components as described in Inlet Boundary Conditions for the LES Model (in the Theory Guide). For all boundary types other than velocity inlets, the boundary conditions for LES remain the same as for laminar flows.

11.18. Providing an Initial Guess for k and ε (or k and ω)

For flows using one of the k-ε models, one of the k-ω models, or the RSM, the converged solutions or (for unsteady calculations) the solutions after a sufficiently long time has elapsed should be independent of the initial values for k and ε (or k and ω). For better convergence, however, it is beneficial to use a reasonable initial guess for k and ε (or k and ω).

In general, it is recommended that you start from a fully-developed state of turbulence. When you use a y^+-insensitive wall treatment, it is critically important to specify fully-developed turbulence fields. Guidelines are provided below.

- If you were able to specify reasonable boundary conditions at the inlet, it may be a good idea to compute the initial values for k and ε (or k and ω) in the whole domain from these boundary values. (See Initializing the Solution (p. 1591) for details.)

- For more complex flows (for example, flows with multiple inlets with different conditions) it may be better to specify the initial values in terms of turbulence intensity. 5–10% is enough to represent fully-developed turbulence. The values of k can then be computed from the turbulence intensity and the characteristic mean velocity magnitude of your problem ($k=1.5\left(Iu_{avg}\right)^2$).

  You should specify an initial guess for ε so that the resulting eddy viscosity ($C_\mu\frac{k^2}{\varepsilon}$) is sufficiently large in comparison to the molecular viscosity. In fully-developed turbulence, the turbulent viscosity is roughly two orders of magnitude larger than the molecular viscosity. From this, you can compute ε.

$$\varepsilon=C_\mu\frac{k^2}{\mu_T}=C_\mu\frac{k^2}{\frac{\mu_T}{\mu}\mu} \tag{11.8}$$

  where $\frac{\mu_T}{\mu}$ is the turbulent viscosity ratio which can be prescribed at the inlet and then used for the domain initialization.

  Note that, for the RSM, Reynolds stresses are initialized automatically using Equation 11.6 (p. 808) and Equation 11.7 (p. 808).

11.19. Solution Strategies for Turbulent Flow Simulations

Compared to laminar flows, simulations of turbulent flows are more challenging in many ways. For the Reynolds-averaged approach, additional equations are solved for the turbulence quantities. Since the equations for mean quantities and the turbulent quantities (μ_t, k, ε, ω, or the Reynolds stresses) are strongly coupled in a highly nonlinear fashion, it takes more computational effort to obtain a converged turbulent solution than to obtain a converged laminar solution. The LES model, while embodying a simpler, algebraic model for the subgrid-scale viscosity, requires a transient solution on a very fine mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The fidelity of the results for turbulent flows is largely determined by the turbulence model being used. Here are some guidelines that can enhance the quality of your turbulent flow simulations.

For additional information, see the following sections:

11.19.1. Mesh Generation
11.19.2. Accuracy
11.19.3. Convergence
11.19.4. RSM-Specific Solution Strategies
11.19.5. LES-Specific Solution Strategies

11.19.1. Mesh Generation

The following are suggestions to follow when generating the mesh for use in your turbulent flow simulation:

- First imagine the flow under consideration, then identify the main flow features expected in the flow using your physical intuition or any data for a similar flow situation. Generate a mesh that can resolve the major features that you expect.
- If the flow is wall-bounded and the wall is expected to affect the flow significantly, you should take additional care when generating the mesh. See Grid Resolution for RANS Models (p. 756) and Wall Boundary Layers (p. 760) for guidelines.

11.19.2. Accuracy

The suggestions below are provided to help you obtain better accuracy in your results:

- Use the turbulence model that is better suited for the salient features you expect to see in the flow (see Choosing a Turbulence Model (p. 751)).
- Because the mean quantities have larger gradients in turbulent flows than in laminar flows, it is recommended that you use high-order schemes for the convection terms. This is especially true if you employ a triangular or tetrahedral mesh. Note that excessive numerical diffusion adversely affects the solution accuracy, even with the most elaborate turbulence model.
- In some flow situations involving inlet boundaries, the flow downstream of the inlet is dictated by the boundary conditions at the inlet. In such cases, you should exercise care to make sure that reasonably realistic boundary values are specified.

11.19.3. Convergence

The suggestions below are provided to help you enhance convergence for turbulent flow calculations:

- Starting with excessively crude initial guesses for mean and turbulence quantities may cause the solution to diverge. A safe approach is to start your calculation using conservative (small) under-relaxation parameters and (for the density-based solvers) a conservative Courant number, and increase them gradually as the iterations proceed and the solution begins to settle down.
- It is also helpful for faster convergence to start with reasonable initial guesses for the k and ε (or k and ω) fields. Particularly when a y^+-insensitive wall treatment is used, it is important to start with a sufficiently developed turbulence field, as recommended in Providing an Initial Guess for k and ε (or k and ω) (p. 810), to avoid the need for an excessive number of iterations to develop the turbulence field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- When you are using the RNG k-ε model, an approach that might help you achieve better convergence is to obtain a solution with the standard k-ε model before switching to the RNG model. Due to the additional nonlinearities in the RNG model, lower under-relaxation factors and (for the density-based solvers) a lower Courant number might also be necessary.

Note that when you use the enhanced wall treatment (EWT-ε), you may sometimes find during the calculation that the residual for ε is reported to be zero. This happens when your flow is such that Re_y is less than 200 in the entire flow domain, and ε is obtained from the algebraic formula (Equation 4.342 in the Theory Guide) instead of from its transport equation.

11.19.4. RSM-Specific Solution Strategies

Using the RSM creates a high degree of coupling between the momentum equations and the turbulent stresses in the flow, and therefore the calculation can be more prone to stability and convergence difficulties than with the k-ε models. When you use the RSM, therefore, you may need to adopt special solution strategies in order to obtain a converged solution. The following strategies are generally recommended:

- Begin the calculations using the standard k-ε model. Turn on the RSM and use the k-ε solution data as a starting point for the RSM calculation.

- Use low under-relaxation factors (0.2 to 0.3) and (for the density-based solvers) a low Courant number for highly swirling flows or highly complex flows. In these cases, you may need to reduce the under-relaxation factors both for the velocities and for all of the stresses.

Instructions for setting these solution parameters are provided below. If you are applying the RSM to prediction of a highly swirling flow, you will want to consider the solution strategies discussed in Swirling and Rotating Flows (p. 587) as well.

11.19.4.1. Under-Relaxation of the Reynolds Stresses

ANSYS Fluent applies under-relaxation to the Reynolds stresses. You can set under-relaxation factors using the Solution Controls Task Page (p. 2508).

Solution → Controls

The default settings of 0.5 are recommended for most cases. You may be able to increase these settings and speed up the convergence when the RSM solution begins to converge.

In some situations, when poor convergence is observed one might facilitate the convergence rates by modifying some of the under-relaxation values whilst leaving the others unchanged. This might be a more successful approach than the simple scaling of all under-relaxation values.

11.19.4.2. Disabling Calculation Updates of the Reynolds Stresses

In some instances, you may want to let the current Reynolds stress field remain fixed, skipping the solution of the Reynolds transport equations while solving the other transport equations. You can enable/disable all Reynolds stress equations in the **Equations** dialog box.

Solution → Controls → Equations...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.19.4.3. Residual Reporting for the RSM

When you use the RSM for turbulence, ANSYS Fluent reports the equation residuals for the individual Reynolds stress transport equations. You can apply the usual convergence criteria to the Reynolds stress residuals: normalized residuals in the range of 10^{-3} usually indicate a practically-converged solution. However, you may need to apply tighter convergence criteria (below 10^{-4}) to ensure full convergence.

11.19.5. LES-Specific Solution Strategies

Large eddy simulation involves running a transient solution from some initial condition, on an appropriately fine mesh, using an appropriate time step size. The solution must be run long enough to become independent of the initial condition and to enable the statistics of the flow field to be determined.

The following are suggestions to follow when running a large eddy simulation:

1. Start by running a steady-state flow simulation using a Reynolds-averaged turbulence model such as standard k-ε, k-ω, or even RSM. Run until the flow field is reasonably converged and then use the `solve/initialize/ init-instantaneous-vel` text command to generate the instantaneous velocity field out of the steady-state RANS results. This command must be executed before LES is enabled. This option is available for all RANS-based models and it will create a much more realistic initial field for the LES run. Additionally, it will help in reducing the time needed for the LES simulation to reach a statistically stable mode. This step is optional.

2. When you enable LES, ANSYS Fluent will automatically turn on the unsteady solver option and choose the second-order implicit formulation. You will need to set the appropriate time step size and all the needed solution parameters. (See User Inputs for Time-Dependent Problems (p. 1609) for guidelines on setting solution parameters for transient calculations in general.) The bounded central differencing spatial discretization scheme will be automatically enabled for momentum equations. Both the bounded central-differencing and pure central-differencing schemes are available for all equations when running LES simulations.

3. Run LES until the flow becomes statistically steady. The best way to see if the flow is fully developed and statistically steady is to monitor forces and solution variables (for example, velocity components or pressure) at selected locations in the flow.

4. Zero out the initial statistics using the `solve/initialize/init-flow-statistics` text command. Before you restart the solution, enable **Data Sampling for Time Statistics** in the Run Calculation Task Page (p. 2537), as described in User Inputs for Time-Dependent Problems (p. 1609). With this option enabled, ANSYS Fluent will gather data for time statistics while performing a large eddy simulation. You can set the **Sampling Interval** such that **Data Sampling for Time Statistics** can be performed at the specified frequency. When **Data Sampling for Time Statistics** is enabled, the statistics collected at each sampling interval can be postprocessed and you can then view both the mean and the root-mean-square-error (RMSE) values in ANSYS Fluent. The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean and RMSE values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

5. Continue until you get statistically stable data. The duration of the simulation can be determined beforehand by estimating the mean flow residence time in the solution domain (L/U, where L is the characteristic length of the solution domain and U is a characteristic mean flow velocity). The simulation should be run for at least a few mean flow residence times.

Instructions for setting the solution parameters for LES are provided below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

11.19.5.1. Temporal Discretization

ANSYS Fluent provides both first-order and second-order temporal discretizations. For LES, the second-order discretization is recommended.

Solution → **Methods**

11.19.5.2. Spatial Discretization

Overly diffusive schemes such as the first-order upwind or power law scheme should be avoided, because they may unduly damp out the energy of the resolved eddies. The central-differencing based schemes are recommended for all equations when you use the LES model. ANSYS Fluent provides two central-differencing based schemes: *pure* central-differencing and *bounded* central-differencing. The bounded scheme is the default option when you select LES, DES, SDES, or SBES.

Solution → **Methods**

11.20. Postprocessing for Turbulent Flows

ANSYS Fluent provides postprocessing options for displaying, plotting, and reporting various turbulence quantities, which include the main solution variables and other auxiliary quantities.

Turbulence quantities that can be reported for the Spalart-Allmaras model are as follows:

- **Modified Turbulent Viscosity**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Yplus**
- **Curvature Correction Function fr** (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the DES model in combination with the Spalart-Allmaras model are as follows:

- all of the quantities available for the Spalart-Allmaras model
- **DES TKE Dissipation Multiplier**
- **Normalized Q criterion**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Q criterion**

> **Note**
>
> For a Detached Eddy Simulation with the Spalart-Allmaras model, the **DES TKE Dissipation Multiplier** represents the function f_d in Equation 4.250.

Turbulence quantities that can be reported for the k-ε models are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)** (only when the enhanced wall treatment is used for the near-wall treatment)
- **Curvature Correction Function fr** (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the DES model in combination with the Realizable k-ε model are as follows:

- all of the quantities available for the Realizable k-ε model
- **DES TKE Dissipation Multiplier**
- **Normalized Q criterion**
- **Q criterion**

> **Note**
>
> For a Detached Eddy Simulation with the Realizable k-ε model, the **DES TKE Dissipation Multiplier** represents the function f_d in Equation 4.257.

Turbulence quantities that can be reported for the k-ω models are as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Intermittency**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**
- **Curvature Correction Function fr** (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the Standard and BSL k-ω model in combination with the SAS model are as follows:

- all of the quantities available for the k-ω model
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the BSL or SST k-ω model in combination with the DES model are as follows:

- all of the quantities available for the k-ω models
- **DES TKE Dissipation Multiplier**
- **Normalized Q criterion**
- **Q criterion**

Note

For a Detached Eddy Simulation with BSL / SST, **DES TKE Dissipation Multiplier** represents the function F_{DES} in Equation 4.261 and F_{IDDES} in Equation 4.265, depending on the specified model. Within the DES concept, the **DES TKE Dissipation Multiplier** increases the destruction

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

term in the transport equation for the turbulence kinetic energy in LES regions (F_{DES}>1). This increase in destruction terms reduces the eddy viscosity in LES regions.

Turbulence quantities that can be reported for the BSL or SST k-ω model in combination with the Shielded Detached Eddy Simulation (SDES) model or the Stress-Blended Eddy Simulation (SBES) model are as follows:

- all of the quantities available for the k-ω models
- **Shielding Function for SBES or SDES**
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the transition k-kl-ω model are as follows:

- **Turbulent Kinetic Energy (k)**
- **Laminar Kinetic Energy**
- **Total Fluctuation Energy**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Production of laminar k**
- **Turbulent Viscosity**
- **Turbulent Viscosity (large-scale)**
- **Turbulent Viscosity (small-scale)**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)**

Turbulence quantities that can be reported for the Transition SST model are as follows:

- **Turbulent Kinetic Energy (k)**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**

- **Curvature Correction Function fr** (only when the curvature correction is enabled)

Turbulence quantities that can be reported for the Transition SST model in combination with the SAS model are as follows:

- all of the quantities available for the Transition SST model
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the Transition SST model in combination with the DES model are as follows:

- all of the quantities available for the Transition SST model
- **DES TKE Dissipation Multiplier**
- **Normalized Q criterion**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Q criterion**

Note

For the Transition SST model in combination with the DES model, **DES TKE Dissipation Multiplier** represents the function F_{DES} in Equation 4.264 and F_{IDDES} in Equation 4.265 depending on the specified model. Within the DES concept, the **DES TKE Dissipation Multiplier** increases the destruction term in the transport equation for the turbulence kinetic energy in LES regions (F_{DES}>1). This increase in destruction terms reduces the eddy viscosity in LES regions.

Turbulence quantities that can be reported for the Transition SST model in combination with the Shielded Detached Eddy Simulation (SDES) model or the Stress-Blended Eddy Simulation (SBES) model are as follows:

- all of the quantities available for the Transition SST model
- **Shielding Function for SBES or SDES**
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the RSM are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **UU Reynolds Stress**
- **VV Reynolds Stress**
- **WW Reynolds Stress**
- **UV Reynolds Stress**
- **VW Reynolds Stress**
- **UW Reynolds Stress**
- **Turbulent Dissipation Rate (Epsilon)**
- **Specific Dissipation Rate (Omega)** (ω-based Reynolds stress models only)
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Turbulent Reynolds Number (Re_y)** (ε-based Reynolds stress models only)

Turbulence quantities that can be reported for the ω-based Reynolds stress models in combination with the SAS model are as follows:

- all of the quantities available for the RSM model
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the SAS model in combination with the SST k-ω model are as follows:

- **Turbulent Kinetic Energy (k)**
- **Turbulent Intensity**
- **Turbulent Dissipation Rate (Epsilon)**
- **Intermittency**
- **Specific Dissipation Rate (Omega)**
- **Production of k**
- **Turbulent Viscosity**
- **Effective Viscosity**
- **Turbulent Viscosity Ratio**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Yplus**
- **Wall Ystar**
- **Curvature Correction Function fr** (only when the curvature correction is enabled)
- **Normalized Q criterion**
- **Q criterion**

Turbulence quantities that can be reported for the LES model are as follows:

- **Turbulence Kinetic Energy**
- **Turbulence Intensity**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Subgrid Kinetic Energy**
- **Production of k**
- **Subgrid Turbulent Viscosity**
- **Subgrid Effective Viscosity**
- **Subgrid Turbulent Viscosity Ratio**
- **Subgrid Filter Length**
- **Subgrid Test-Filter Length**
- **Subgrid Dissipation Rate**
- **Subgrid Dynamic Viscosity Const**
- **Subgrid Dynamic Prandtl Number**
- **Subgrid Dynamic Sc of Species**
- **Subtest Kinetic Energy**
- **Effective Thermal Conductivity**
- **Effective Prandtl Number**
- **Wall Ystar**
- **Wall Yplus**
- **Normalized Q criterion**
- **Q criterion**

Additional turbulence quantities can be reported for the Embedded LES (ELES) model.

Note

Within the Embedded LES zone, the modeled eddy viscosity is determined by an algebraic subgrid-scale eddy viscosity model. The global turbulence model is either frozen or, if it is either SAS, DES, SDES, or SBES with an underlying two-equation RANS model, runs in a "passive mode", that is without affecting the momentum equations.

Hence, most turbulence postprocessing in the Embedded LES zone refers to the frozen or "passive" global turbulence model. Special care is necessary with the modeled eddy viscosity, because there are two to consider: one from the frozen / passive global turbulence model; and one from the "local" algebraic subgrid-scale model that is running within the Embedded LES zone and actually affects the momentum equations.

- Some postprocessing quantities refer to a "passive" global turbulence model or are zero if the global model cannot run in "passive" mode and therefore is frozen in the Embedded LES zone.
  - **Turbulent Viscosity**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - **Turbulent Viscosity Ratio**

- In the Embedded LES zone, the subgrid-scale eddy viscosity from the local algebraic model, which actually affects the momentum equations, is displayed as:

  - **LES Subgrid Turbulent Viscosity**

- The following quantities are specific to the Dynamic LES subgrid-scale eddy viscosity models. They are available in Embedded LES zones if the **Dynamic Smagorinsky** model is used in any Embedded LES zone; they are also available for global LES when the **Smagorinsky-Lilly** subgrid-scale model is selected with the **Dynamic Stress** option enabled or when the **Kinetic-Energy Transport** subgrid-scale model is selected:

  - **Subgrid Test-Filter Length**

  - **Subgrid Dynamic Viscosity Const**

  - **Subtest Kinetic Energy**

All of these variables can be found in the **Turbulence...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1931) for their definitions.

For additional information, see the following sections:
11.20.1. Custom Field Functions for Turbulence
11.20.2. Postprocessing Turbulent Flow Statistics
11.20.3. Troubleshooting

11.20.1. Custom Field Functions for Turbulence

In addition to the quantities listed in Postprocessing for Turbulent Flows (p. 814), above, you can define your own turbulence quantities using the Custom Field Function Calculator Dialog Box (p. 2683).

User-Defineed → Field Functions → Custom...

The following functions may be useful:

- the ratio of production of k to its dissipation ($G_k / \rho\varepsilon$)

- the ratio of the mean flow to turbulent time scale, η ($\equiv Sk / \varepsilon$)

- the Reynolds stresses derived from the Boussinesq formula (for example, $-\overline{uv} = \nu_t \frac{\partial u}{\partial y}$)

11.20.2. Postprocessing Turbulent Flow Statistics

As described in Large Eddy Simulation (LES) Model (in the Theory Guide), LES involves the solution of a transient flow field, but it is the mean flow quantities that are of interest from an engineering standpoint.

For all other turbulent flow, if **Data Sampling for Time Statistics** is enabled in the Run Calculation Task Page (p. 2537), ANSYS Fluent gathers data for time statistics while performing the simulation. The statistics that ANSYS Fluent collects at each sampling interval (which consists of the mean and the root-mean-square-error (RMSE) values) can be postprocessed by selecting **Unsteady Statistics...** in any of the postprocessing dialog boxes. You can view several variables that include, but are not limited to, shear stresses (**Resolved UV/UW/VW Reynolds Stress**), flow heat fluxes (**Resolved UT/VT/WT Heat**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Flux), and species statistics (**RMSE Mass Fraction of** species and **Mean Mass Fraction** of species). If you select **Unsteady Wall Statistics...** in any of the postprocessing dialog boxes, you can view wall statistics such as **Mean Pressure Coefficient**, **Mean Wall Shear Stress**, **Mean X-Wall Shear Stress**, **Mean Y-Wall Shear Stress**, **Mean Z-Wall Shear Stress**, **Mean Skin Friction Coefficient**, **Mean Surface Heat Flux**, **Mean Surface Heat Transfer Coef.**, **Mean Surface Nusselt Number**, **Mean Surface Stanton Number**. Note that these quantities are only the statistical evaluation of sampled solution data, and do not contain any kind of modeled turbulent fluctuations. See Postprocessing for Time-Dependent Problems (p. 1622) for details.

The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean and RMSE values. As long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

Important

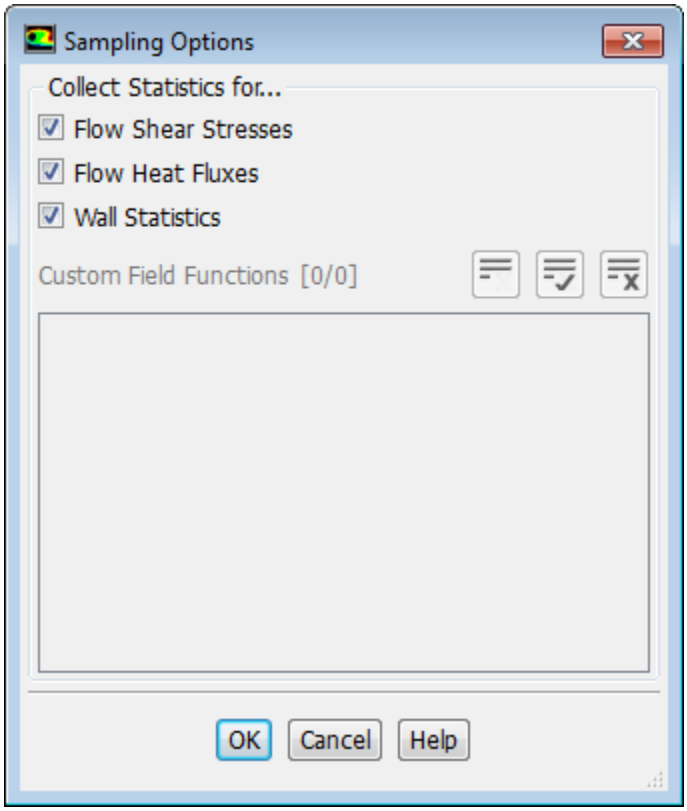
Note that *mean* statistics are collected only in interior cells and not on wall surfaces. Therefore, when node or cell values of mean quantities are plotted on the wall surface, you are actually plotting values in nearby cells attached to the wall.

If you want to control what set of variables are available for postprocessing, open the **Sampling Options** dialog box and enable or disable the statistics shown in Figure 11.26: The Sampling Options Dialog Box (p. 824).

Solution → **Run Calculation** → **Sampling Options...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 11.26: The Sampling Options Dialog Box



Important

When including or excluding statistics on variables, it is recommended that you re-initialize the flow statistics.

11.20.3. Troubleshooting

You can use the postprocessing options not only for the purpose of interpreting your results but also for investigating any anomalies that may appear in the solution. For instance, you may want to plot contours of the k field to check if there are any regions where k is erroneously large or small. You should see a high k region in the region where the production of k is large. You may want to display the turbulent viscosity ratio field in order to see whether or not the turbulence takes full effect. Usually the turbulent viscosity is at least two orders of magnitude larger than molecular viscosity for fully-developed turbulent flows modeled using the RANS approach (that is, not using LES). You may also want to check whether you are using an adequate near-wall mesh when using a y^+-insensitive wall treatment (see Grid Resolution for RANS Models (p. 756) for guidelines). For EWT-ε, you can also display filled contours of Re_y (turbulent Reynolds number) overlaid on the mesh (see Enhanced Wall Treatment ε-Equation (EWT-ε) in the Theory Guide for more details).

Chapter 12: Modeling Heat Transfer

This chapter provides details about the heat transfer models available in ANSYS Fluent. Information is presented in the following sections:

12.1. Introduction
12.2. Modeling Conductive and Convective Heat Transfer
12.3. Modeling Radiation
12.4. Modeling Periodic Heat Transfer

12.1. Introduction

The flow of thermal energy from matter occupying one region in space to matter occupying a different region in space is known as heat transfer. Heat transfer can occur by three main mechanisms: conduction, convection, and radiation. Physical models involving conduction and/or convection only are the simplest (Modeling Conductive and Convective Heat Transfer (p. 825)), while buoyancy-driven flow or natural convection (Natural Convection and Buoyancy-Driven Flows (p. 833)), and flow involving radiation (Modeling Radiation (p. 845)) are more complex. Depending on your problem, ANSYS Fluent will solve a variation of the energy equation that takes into account the heat transfer methods you have specified. ANSYS Fluent is also able to predict heat transfer in periodically repeating geometries (Modeling Periodic Heat Transfer (p. 912)), therefore greatly reducing the required computational effort in certain cases.

12.2. Modeling Conductive and Convective Heat Transfer

ANSYS Fluent allows you to include heat transfer within the fluid and/or solid regions in your model. Problems ranging from thermal mixing within a fluid to conduction in composite solids can therefore be handled by ANSYS Fluent.

When your ANSYS Fluent model includes heat transfer you will need to enable the relevant physical models, supply thermal boundary conditions, and enter material properties (which may vary with temperature) that govern heat transfer. For information about heat transfer theory, see Heat Transfer Theory in the Theory Guide. Information about heat transfer theory and how to set up and use heat transfer in your ANSYS Fluent model is presented in the following subsections:

12.2.1. Solving Heat Transfer Problems
12.2.2. Solution Strategies for Heat Transfer Modeling
12.2.3. Postprocessing Heat Transfer Quantities
12.2.4. Natural Convection and Buoyancy-Driven Flows
12.2.5. Shell Conduction Considerations

12.2.1. Solving Heat Transfer Problems

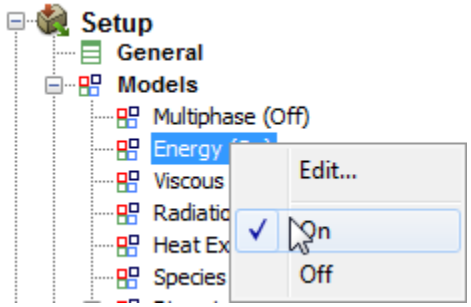
The procedure for setting up a heat transfer problem is described below. Note that this procedure includes only those steps necessary for the heat transfer model itself; you will need to define the other settings (for example, other models, boundary conditions) as usual.

1. To activate the calculation of heat transfer, enable the energy equation by right-clicking **Energy** in the tree (under **Setup/Models**) and clicking **On** in the menu that opens.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Energy → On

Figure 12.1: Enabling the Energy Equation



2. (Optional, pressure-based solver only.) If you are modeling viscous flow and you want to include the viscous heating terms in the energy equation, enable the **Viscous Heating** option in the **Viscous Model** dialog box.

   Setup → Models → Viscous → Edit...

   As noted in Inclusion of the Viscous Dissipation Terms in the Theory Guide, the viscous heating terms in the energy equation are (by default) ignored by ANSYS Fluent when the pressure-based solver is used. They are always included for the density-based solver. Viscous dissipation should be enabled when the shear stress in the fluid is large (for example, in lubrication problems) and/or in high-velocity, compressible flows. See Equation 5.9 in the Theory Guide.

3. Define thermal boundary conditions at flow inlets, flow outlets, and walls. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

   Setup → Boundary Conditions

   At flow inlets and exits you will set the temperature; at walls you may use any of the following thermal conditions:

   - specified heat flux
   - specified temperature
   - convective heat transfer
   - external radiation
   - combined external radiation and external convective heat transfer

   Thermal Boundary Conditions at Walls (p. 370) provides details on the model inputs that govern these thermal boundary conditions. The default thermal boundary condition at inlets is a specified

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

temperature of 300 K; at walls the default condition is zero heat flux (adiabatic). See Cell Zone and Boundary Conditions (p. 237) for details about boundary condition inputs.

Important

If your heat transfer application involves two separated fluid regions, see the information provided below.

4. Define material properties for heat transfer.

   Setup → Materials

   Heat capacity and thermal conductivity must be defined, and you can specify many properties as functions of temperature as described in Physical Properties (p. 459).

12.2.1.1. Limiting the Predicted Temperature Range

For stability reasons, ANSYS Fluent includes a limit on the predicted temperature range. The purpose of the temperature ceiling and floor is to improve the stability of calculations in which the temperature should physically lie within known limits. Sometimes intermediate solutions of the equations give rise to temperatures beyond these limits for which property definitions, and so on, are not well defined.

The temperature limits keep the temperatures within the expected range for your problem. If the ANSYS Fluent calculation predicts a temperature above the maximum limit, the stored temperature values are "pegged" at this maximum value. The default for the temperature ceiling is 5000 K. If the ANSYS Fluent calculation predicts a temperature below the minimum limit, the stored temperature values are "pegged" at this minimum value. The default for the temperature minimum is 1 K.

If you expect the temperature in your domain to exceed 5000 K, use the **Solution Limits** dialog box to increase the **Maximum Static Temperature**.

Solution → Controls → Limits...

12.2.1.2. Modeling Heat Transfer in Two Separated Fluid Regions

If your heat transfer application involves two fluid regions separated by a solid zone or a wall, as illustrated in Figure 12.2: Typical Counterflow Heat Exchanger Involving Heat Transfer Between Two Separated Fluid Streams (p. 828), you will need to define the problem with some care. Specifically:

- You should not use outflow boundary conditions in either fluid.
- You can establish separate fluid properties by selecting a different fluid material for each zone. For species calculations, however, you can only select a single mixture material for the entire domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.2: Typical Counterflow Heat Exchanger Involving Heat Transfer Between Two Separated Fluid Streams

12.2.2. Solution Strategies for Heat Transfer Modeling

Although many simple heat transfer problems can be successfully solved using the default solution parameters assumed by ANSYS Fluent, you may accelerate the convergence of your problem and/or improve the stability of the solution process using some of the guidelines provided in this section.

12.2.2.1. Under-Relaxation of the Energy Equation

When you use the pressure-based solver, ANSYS Fluent under-relaxes the energy equation using the under-relaxation parameter defined by you in the **Solution Controls** task page, as described in Setting Under-Relaxation Factors (p. 1564).

Solution → **Controls**

If you are using the non-adiabatic non-premixed combustion model, you will set the energy under-relaxation factor as usual but you will also set an under-relaxation factor for temperature, as described below.

ANSYS Fluent uses a default under-relaxation factor of 1.0 for the energy equation, regardless of the form in which it is solved (temperature or enthalpy). In problems where the energy field impacts the fluid flow (via temperature-dependent properties or buoyancy) you should use a lower value for the under-relaxation factor, in the range of 0.8–1.0. In problems where the flow field is decoupled from the temperature field (no temperature-dependent properties or buoyancy forces), you can usually retain the default value of 1.0.

12.2.2.2. Under-Relaxation of Temperature When the Enthalpy Equation is Solved

When the enthalpy form of the energy equation is solved (that is, when you are using the non-adiabatic non-premixed combustion model), ANSYS Fluent also under-relaxes the temperature, updating the temperature by only a fraction of the change that would result from the change in the (under-relaxed) enthalpy values. This second level of under-relaxation can be used to good advantage when you would like to let the enthalpy field change rapidly, but the temperature response (and its effect on fluid properties) to lag. ANSYS Fluent uses a default setting of 1.0 for the under-relaxation on temperature and you can modify this setting using the **Solution Controls** task page.

Solution → **Controls**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.2.2.3. Disabling the Species Diffusion Term

If you are solving for species transport using the pressure-based solver and you encounter convergence difficulties, you may want to consider disabling the **Diffusion Energy Source** option in the **Species Model** dialog box.

Setup → Models → Species Edit...

When this option is disabled, ANSYS Fluent will neglect the effects of species diffusion on the energy equation.

Note that species diffusion effects are always included when the density-based solver is used.

12.2.2.4. Step-by-Step Solutions

Often the most efficient strategy for predicting heat transfer is to compute an isothermal flow first and then add the calculation of the energy equation. The procedure differs slightly, depending on whether or not the flow and heat transfer are coupled.

12.2.2.4.1. Decoupled Flow and Heat Transfer Calculations

If your flow and heat transfer are decoupled (no temperature-dependent properties or buoyancy forces), you can first solve the isothermal flow (energy equation turned off) to yield a converged flow-field solution and then solve the energy transport equation alone.

Important

Since the density-based solver always solves the flow and energy equations together, the procedure for solving for energy alone applies to the pressure-based solver, only.

You can temporarily disable the flow equations or the energy equation by deselecting them in the **Equations** dialog box:

Solution → Controls Equations...

You can also disable the energy equation:

Setup → Models → Energy Off

12.2.2.4.2. Coupled Flow and Heat Transfer Calculations

If the flow and heat transfer are coupled (that is, your model includes temperature-dependent properties or buoyancy forces), you can first solve the flow equations before enabling energy. Once you have a converged flow-field solution, you can enable energy and solve the flow and energy equations simultaneously to complete the heat transfer simulation.

12.2.2.5. Specifying a Solid Time step

For transient conjugate heat transfer (CHT) problems, particularly those with combustion, the dominant time-scales in the fluid and solid zones are often quite different. In most cases, it is desirable to have a

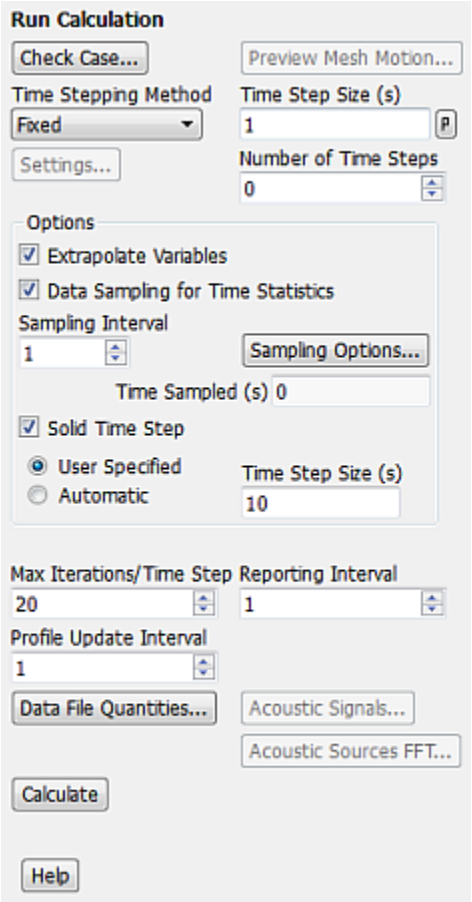
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

larger time step in solid zones, while maintaining a smaller time step in fluid zones. This will increase the speed at which the solid heat transfer reaches steady-state without compromising the solution accuracy of the fluid flow.

You can specify a solid time step on the **Run Calculation** task page:

Solution → Run Calculation

Figure 12.3: The Run Calculation Task Page Showing Solid Time Step



1. Under **Options**, select **Solid Time Step**.
2. Use the default **Automatic** time step or select **User Specified** to enter your own time step.

12.2.2.5.1. Automatic Time Step Calculation

The default **Automatic** time step is calculated by ANSYS Fluent using the following formula:

$$\Delta t_{solid} = \frac{L_{scale_solid}^2}{\alpha} \tag{12.1}$$

where,

- L_{scale_solid} is the representative length scale and is calculated as $\sqrt[3]{Solid_Volume}$.
- α is $\frac{k}{\rho c_p}$, the representative velocity scale, where k is the conductivity, ρ is the density, and c_p is the specific heat capacity of the solid.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The calculation for Δt_{solid} results in an approximation for the solid time step which might aide in the solution running more efficiently. It should be noted, however, that this is only an engineering approximation as there is no general way to calculate a meaningful length scale for an arbitrary geometry.

12.2.3. Postprocessing Heat Transfer Quantities

For information about postprocessing heat transfer quantities, see the following sections:

12.2.3.1. Available Variables for Postprocessing
12.2.3.2. Definition of Enthalpy and Energy in Reports and Displays
12.2.3.3. Reporting Heat Transfer Through Boundaries
12.2.3.4. Reporting Heat Transfer Through a Surface
12.2.3.5. Reporting Averaged Heat Transfer Coefficients
12.2.3.6. Exporting Heat Flux Data

12.2.3.1. Available Variables for Postprocessing

ANSYS Fluent provides reporting options for simulations involving heat transfer. You can generate graphical plots or reports of the following variables/functions:

- **Static Temperature**
- **Total Temperature**
- **Enthalpy**
- **Relative Total Temperature**
- **Rothalpy**
- **Wall Temperature**
- **Wall Temperature (Thin)**
- **Total Enthalpy**
- **Total Enthalpy Deviation**
- **Entropy**
- **Total Energy**
- **Internal Energy**
- **Total Surface Heat Flux**
- **Surface Heat Transfer Coef.**
- **Surface Nusselt Number**
- **Surface Stanton Number**

The first 12 variables listed above are contained in the **Temperature...** category of the variable selection drop-down list that appears in postprocessing dialog boxes, and the remaining variables are in the **Wall Fluxes...** category. See Field Function Definitions (p. 1931) for their definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.2.3.2. Definition of Enthalpy and Energy in Reports and Displays

The reported enthalpy values may be different between the pressure-based and density-based solver depending on the properties of the working fluid, compressible, incompressible, ideal gas, etc. For details, see the discussion of enthalpy in The Energy Equation in chapter 5, Heat Transfer of the Theory Guide.

12.2.3.3. Reporting Heat Transfer Through Boundaries

You can use the **Flux Reports** dialog box to compute the heat transfer through each boundary of the domain, or to sum the heat transfer through all boundaries to check the heat balance.

Results → **Reports** → **Fluxes** **Edit...**

It is recommended that you perform a heat balance check to ensure that your solution is truly converged.

12.2.3.4. Reporting Heat Transfer Through a Surface

You can use the **Surface Integrals** dialog box to compute the heat transfer through any boundary or any surface created using the methods described in Creating Surfaces and Cell Registers for Displaying and Reporting Data (p. 1709).

Results → **Reports** → **Surface Integrals** **Edit...**

To report the mass flow rate of enthalpy

$$Q = \int H \rho \vec{v} \cdot d\vec{A} \tag{12.2}$$

choose **Flow Rate** for the **Report Type** in the **Surface Integrals** dialog box, select **Enthalpy** (in the **Temperature...** category) as the **Field Variable**, and select the surface(s) on which to integrate.

12.2.3.5. Reporting Averaged Heat Transfer Coefficients

The **Surface Integrals** dialog box can also be used to generate a report of averaged heat transfer coefficient h on a surface ($\frac{1}{A}\int h dA$).

Results → **Reports** → **Surface Integrals** **Edit...**

In the **Surface Integrals** dialog box, choose **Area-Weighted Average** for **Report Type**, select **Surface Heat Transfer Coef.** (in the **Wall Fluxes...** category) as the **Field Variable**, and select the surface.

12.2.3.6. Exporting Heat Flux Data

It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. To save a heat flux file, you will use the `custom-heat-flux` text command.

`file` → `export` → `custom-heat-flux`

Heat transfer data will be exported in the following free format for each face zone that you select for export:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
zone-name nfaces
x_f y_f z_f A Q T_w T_c HTC
.
.
.
```

Each block of data starts with the name of the face zone (`zone-name`) and the number of faces in the zone (`nfaces`). Next there is a line for each face (that is, `nfaces` lines), each containing the components of the face centroid (`x_f`, `y_f`, and, in 3D, `z_f`), the face area (A), the heat transfer rate (Q), the face temperature (T_w), the adjacent cell temperature (T_c), and the heat transfer coefficient (HTC). If the heat transfer coefficient is calculated based on wall function (Equation 33.55 (p. 2001)), then Q is the convective heat transfer rate. Otherwise, Q will be the total heat transfer rate, including radiation heat transfer.

12.2.4. Natural Convection and Buoyancy-Driven Flows

When heat is added to a fluid and the fluid density varies with temperature, a flow can be induced due to the force of gravity acting on the density variations. Such buoyancy-driven flows are termed natural-convection (or mixed-convection) flows and can be modeled by ANSYS Fluent.

For more information about the theory behind natural convection and buoyancy-driven flows, see Natural Convection and Buoyancy-Driven Flows Theory in the Theory Guide.

12.2.4.1. Modeling Natural Convection in a Closed Domain

When you model natural convection inside a closed domain, the solution will depend on the mass inside the domain. Since this mass will not be known unless the density is known, you must model the flow in one of the following ways:

- Perform a transient calculation. In this approach, the initial density will be computed from the initial pressure and temperature, so the initial mass is known. As the solution progresses over time, this mass will be properly conserved. If the temperature differences in your domain are large, you must follow this approach.
- Perform a steady-state calculation using the Boussinesq model (described in The Boussinesq Model (p. 833)). In this approach, you will specify a constant density, so the mass is properly specified. This approach is valid only if the temperature differences in the domain are small. If not, you use the transient approach.

Important

For a closed domain, you can use the *incompressible* ideal gas law only with a *fixed* operating pressure. It *cannot* be used with a floating operating pressure. You can use the *compressible* ideal gas law with either *floating* or *fixed* operating pressure.

See Floating Operating Pressure (p. 597) for more information about the floating operating pressure option.

12.2.4.2. The Boussinesq Model

For many natural-convection flows, you can get faster convergence with the Boussinesq model than you can get by setting up the problem with fluid density as a function of temperature. This model treats density as a constant value in all solved equations, except for the buoyancy term in the momentum equation:

$$\left(\rho-\rho_0\right)g \approx -\rho_0\beta\left(T-T_0\right)g \tag{12.3}$$

where ρ_0 is the (constant) density of the flow, T_0 is the operating temperature, and β is the thermal expansion coefficient. Equation 12.3 (p. 833) is obtained by using the Boussinesq approximation $\rho=\rho_0\left(1-\beta\Delta T\right)$ to eliminate ρ from the buoyancy term. This approximation is accurate as long as changes in actual density are small; specifically, the Boussinesq approximation is valid when $\beta\left(T-T_0\right)\ll 1$.

12.2.4.3. Limitations of the Boussinesq Model

The Boussinesq model should not be used if the temperature differences in the domain are large. In addition, it cannot be used with species calculations, combustion, or reacting flows.

12.2.4.4. Steps in Solving Buoyancy-Driven Flow Problems

The procedure for including buoyancy forces in the simulation of mixed or natural convection flows is described below.

1. To activate the calculation of heat transfer, enable the energy equation by right-clicking **Energy** in the tree (under **Setup/Models**) and clicking **On** in the menu that opens (Figure 12.1: Enabling the Energy Equation (p. 826)).

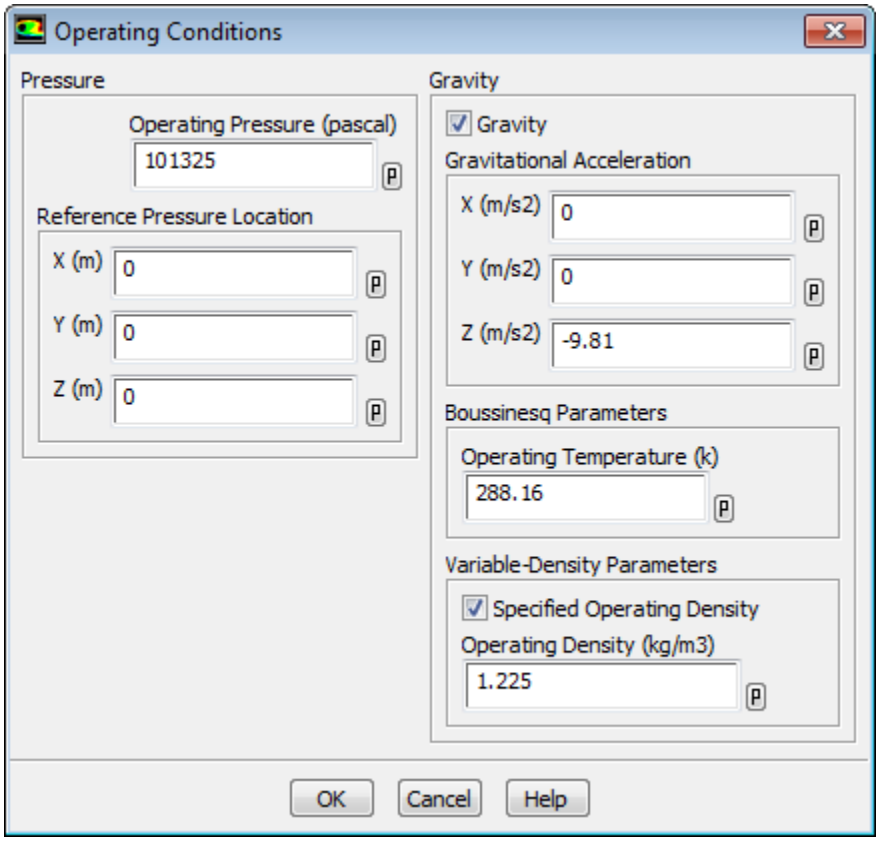
   Setup → **Models** → **Energy** → **On**

2. Define the operating conditions in the **Operating Conditions** dialog box (Figure 12.4: The Operating Conditions Dialog Box (p. 835)).

   Setup → **Cell Zone Conditions** → **Operating Conditions...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.4: The Operating Conditions Dialog Box



a. Enable the **Gravity** option under **Gravity**.

b. Enter the appropriate values in the **X**, **Y**, and (for 3D) **Z** fields for **Gravitational Acceleration** for each Cartesian coordinate direction. (Note that the default gravitational acceleration in ANSYS Fluent is zero.)

c. If you are using the incompressible ideal gas law, check that the **Operating Pressure** is set to an appropriate (nonzero) value.

d. Depending on whether or not you use the Boussinesq approximation, specify the appropriate parameters described below:

- If you are not using the Boussinesq model, the inputs are as follows:

  i. If necessary, enable the **Specified Operating Density** option in the **Operating Conditions** dialog box, and enter a value for the **Operating Density**. See below for details.

  ii. Define the fluid density as a function of temperature as described in Defining Properties Using Temperature-Dependent Functions (p. 475) and Density (p. 479).

  Setup → Materials

- If you are using the Boussinesq model (described in The Boussinesq Model (p. 833)) the inputs are as follows:

  i. Enter the **Operating Temperature** (T_0 in Equation 12.3 (p. 833)) in the **Operating Conditions** dialog box.

ii. Select **boussinesq** in the drop-down list for **Density** in the **Create/Edit Materials** dialog box as described in Defining Properties Using Temperature-Dependent Functions (p. 475) and Density (p. 479), and enter a constant value.

iii. Also in the **Create/Edit Materials** dialog box, enter an appropriate value for the **Thermal Expansion Coefficient** (β in Equation 12.3 (p. 833)) for the fluid material.

Note that if your model involves multiple fluid materials you can choose whether or not to use the Boussinesq model for each material. As a result, you may have some materials using the Boussinesq model and others not. In such cases, you will need to set all the parameters described above in this step.

3. Define the boundary conditions. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

Setup → **Boundary Conditions**

The boundary pressures that you specify at pressure inlet and outlet boundaries are the redefined pressures as given by Equation 12.4 (p. 836). In general you should enter equal pressures, p', at the inlet and exit boundaries of your ANSYS Fluent model if there are no externally imposed pressure gradients.

4. Set the parameters that control the solution, using the **Solution Methods** task page.

Solution → **Methods**

a. Select **Body Force Weighted** or **Second Order** in the drop-down list for **Pressure** under **Spatial Discretization** in the **Solution Methods** task page.

b. If you are using the pressure-based solver, selecting **PRESTO!** for **Pressure** under **Spatial Discretization** is recommended.

c. Add cells near the walls to resolve boundary layers, if necessary.

See also Solving Heat Transfer Problems (p. 825) for information on setting up heat transfer calculations.

12.2.4.5. Operating Density

When the Boussinesq approximation is not used, the operating density ρ_0 appears in the body-force term in the momentum equations as $\left(\rho-\rho_0\right)g$. This form of the body-force term follows from the redefinition of pressure in ANSYS Fluent as

$$p_s'=p_s-\rho_0 g x \tag{12.4}$$

The hydrostatic pressure in a fluid at rest is then

$$p_s'=0 \tag{12.5}$$

12.2.4.5.1. Setting the Operating Density

By default, ANSYS Fluent will compute the operating density by averaging over all cells. In some cases, you may obtain better results if you explicitly specify the operating density instead of having the solver compute it for you. For example, if you are solving a natural-convection problem with a pressure

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

boundary, it is important to understand that the pressure you are specifying is p_s' in Equation 12.4 (p. 836). Although you will know the actual pressure p_s, you will need to know the operating density ρ_0 in order to determine p_s' from p_s. Therefore, you should explicitly specify the operating density rather than use the computed average. The specified value should, however, be representative of the average value.

In some cases the specification of an operating density will improve convergence behavior, rather than the actual results. For such cases use the approximate bulk density value as the operating density and be sure that the value you choose is appropriate for the characteristic temperature in the domain.

Note that if you are using the Boussinesq approximation for all fluid materials, the operating density ρ_0 does not appear in the body-force term of the momentum equation. Consequently, you need not specify it.

12.2.4.6. Solution Strategies for Buoyancy-Driven Flows

For high-Rayleigh-number flows you may want to consider the solution guidelines below. In addition, the guidelines presented in Solution Strategies for Heat Transfer Modeling (p. 828) for solving other heat transfer problems can also be applied to buoyancy-driven flows. No steady-state solution exists for some laminar, high-Rayleigh-number flows.

12.2.4.6.1. Guidelines for Solving High-Rayleigh-Number Flows

When you are solving a high-Rayleigh-number flow ($Ra > 10^8$), you should follow one of the procedures outlined below for best results.

The first procedure uses a steady-state approach:

1. Start the solution with a lower value of Rayleigh number (for example, 10^7) and run it to convergence using the first-order scheme.
2. To change the effective Rayleigh number, change the value of gravitational acceleration (for example, from 9.8 to 0.098 to reduce the Rayleigh number by two orders of magnitude).
3. Use the resulting data file as an initial guess for the higher Rayleigh number and start the higher-Rayleigh-number solution using the first-order scheme.
4. After you obtain a solution with the first-order scheme you may continue the calculation with a higher-order scheme.

The second procedure uses a time-dependent approach to obtain a steady-state solution [41] (p. 2889):

1. Start the solution from a steady-state solution obtained for the same or a lower Rayleigh number.
2. Estimate the time constant as [10] (p. 2887)

$$\tau = \frac{L}{U} \sim \frac{L^2}{\alpha}\left(PrRa\right)^{-1/2} = \frac{L}{\sqrt{g\beta\Delta TL}} \tag{12.6}$$

   where L and U are the length and velocity scales, respectively. Use a time step Δt such that

$$\Delta t \approx \frac{\tau}{4} \tag{12.7}$$

   Using a larger time step Δt may lead to divergence.

3. After oscillations with a typical frequency of $f\tau$= 0.05–0.09 have decayed, the solution reaches steady-state. Note that τ is the time constant estimated in Equation 12.6 (p. 837) and f is the oscillation frequency in Hz. In general this solution process may take as many as 5000 time steps to reach steady-state.

12.2.4.7. Postprocessing Buoyancy-Driven Flows

The postprocessing reports of interest for buoyancy-driven flows are the same as for other heat transfer calculations. See Postprocessing Heat Transfer Quantities (p. 831) for details.

12.2.5. Shell Conduction Considerations

For information about shell conduction considerations, see the following sections:

12.2.5.1. Introduction
12.2.5.2. Physical Treatment
12.2.5.3. Limitations of Shell Conduction Walls
12.2.5.4. Managing Shell Conduction Walls
12.2.5.5. Initializing Shells
12.2.5.6. Locking the Temperature for Shells
12.2.5.7. Postprocessing Shells

12.2.5.1. Introduction

By default, ANSYS Fluent treats walls as having zero-thickness and presenting no thermal resistance to heat transfer across them. If a thickness is specified for a wall (thereby making it a thin wall, as described in Thin-Wall Thermal Resistance Parameters (p. 373)) then the appropriate thermal resistance across the wall thickness is imposed, although conduction is considered in the wall in the normal direction only. There are applications, however, where conduction in the planar directions of the wall is also important. For these applications, you have two options: you can either mesh the thickness, or you can use the shell conduction approach. Shell conduction can be used to model one or more layers of wall cells without the need to mesh the wall thickness in a preprocessor. When the shell conduction approach is utilized, you have the ability to easily switch on and off conjugate heat transfer on any wall. If you create a shell—either by enabling **Shell Conduction** in an individual **Wall** dialog box (as described in Shell Conduction (p. 376)) or by defining multiple walls as shell conduction zones using the **Shell Conduction Manager** dialog box (as described in Managing Shell Conduction Walls (p. 840))—and define the settings for the shell layer(s) using the **Shell Conduction Layers** dialog box, then ANSYS Fluent will automatically grow the specified layers of cells for the wall during the solution process. The cells that are grown will be either prism cells or hex cells, depending on the type of face mesh that is utilized; at no point are the cells visible in the displayed mesh.

Shell conduction can be used to account for thermal mass in transient thermal analysis problems (see Locking the Temperature for Solid and Shell Zones (p. 297) for more information). It can also be used for multiple junctions and allows heat conduction through the junctions. Shell conduction can be applied on boundary walls as well as two-sided walls.

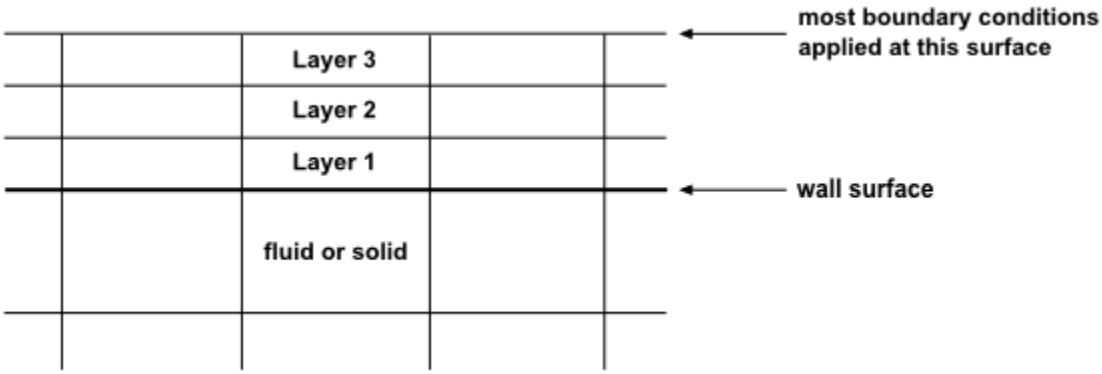
12.2.5.2. Physical Treatment

In the case where shell conduction is applied on a boundary wall, the original surface is referred to as the "wall surface" and is always adjacent to the fluid / solid cells. As part of the solution, layers of wall cells are grown away from the fluid / solid zone. These layers are numbered sequentially, starting with the one closest to the wall surface. See Figure 12.5: A Boundary Wall with Shell Conduction (p. 839) for a visualization of how the solver treats shells.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

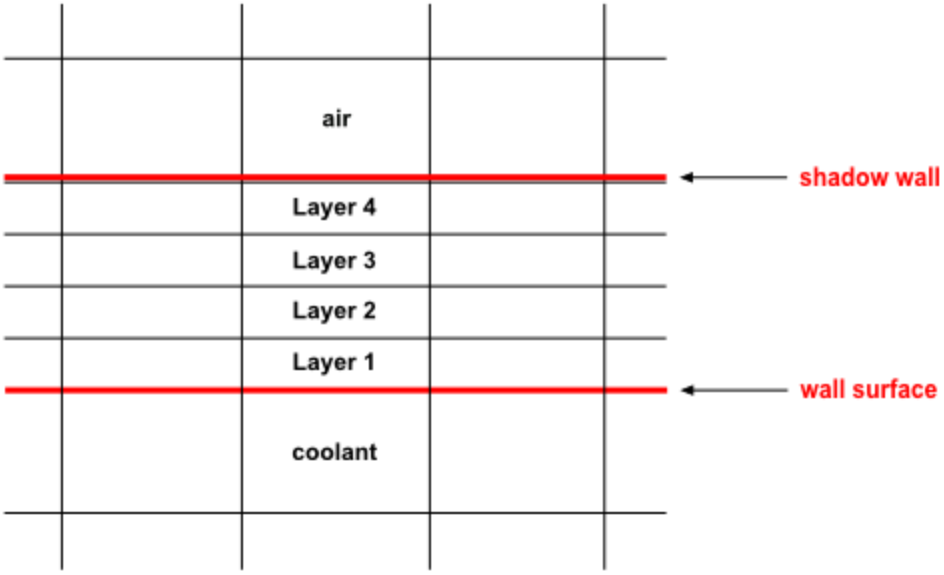
For the most part, the boundary conditions that you specify for the boundary wall are applied to the layer surface that is furthest from the wall surface; only the internal emissivity is applied at the wall surface. The sides of the shell zone require boundary conditions as well. If the shell is connected to another wall that does not have shell conduction enabled, the shell side will take the boundary condition of the attached wall. The sides will be adiabatic if they are connected to face zones that have a boundary condition type other than **wall**. If the attached wall has shell conduction enabled, then the common sides at the junction will be coupled.

Figure 12.5: A Boundary Wall with Shell Conduction



The layers of cells grown for two-sided walls can be visualized in a similar way to Figure 12.5: A Boundary Wall with Shell Conduction (p. 839), except that the layer surface that is furthest from the wall surface is also adjacent to a shadow wall (which is then adjacent to the other fluid / solid zone).

Figure 12.6: A Two-Sided Wall with Shell Conduction



12.2.5.3. Limitations of Shell Conduction Walls

The following is a list of limitations for the shell conduction model:

- Shells cannot be created on non-conformal interfaces, including mapped interfaces.
- Shell conduction cannot be used on moving wall zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Shell conduction cannot be used with FMG initialization.
- Shell conduction is not available when the wall is set up to receive thermal data via system coupling.
- Shell conduction is not available for 2D.
- Shell conduction is available only when the pressure-based solver is used.
- Shell conducting walls cannot be split or merged. If you need to split or merge a shell conducting wall, you will need to turn off the **Shell Conduction** option for the wall (in the **Wall** dialog box), perform the split or merge operation, and then enable **Shell Conduction** for the new wall zones.
- The shell conduction model cannot be used on a wall zone that has been adapted. If you want to perform adaption elsewhere in the computational domain, be sure to use the mask register described in Manipulating Adaption Registers (p. 1701). This will ensure that adaption is not performed on the shell conducting wall.
- Fluxes at the ends of a shell conducting wall are not included in heat balance reports. These fluxes are accounted for correctly in the ANSYS Fluent solution, but are not listed in the flux report.
- The junction of a wall with shell conduction enabled and a non-conformal coupled wall is not supported. Such a junction will not be thermally connected, that is, there will be no heat transfer between the shell and the mesh interface wall.
- When running the parallel solver with the shell conduction model, note that coupled walls are encapsulated. If you encounter problems with the partitioning of the mesh, you can try changing the encapsulation method to see if that resolves the problem (see Troubleshooting (p. 2056) for this and other troubleshooting options).
- When running the parallel solver with the shell conduction model, junctions between coupled walls and periodic boundaries are not supported. An error message will be thrown and shell conduction will be disabled.

12.2.5.4. Managing Shell Conduction Walls

The **Shell Conduction Manager** dialog box provides a convenient way for you to manage, define, and display multiple shell conduction zones. You can

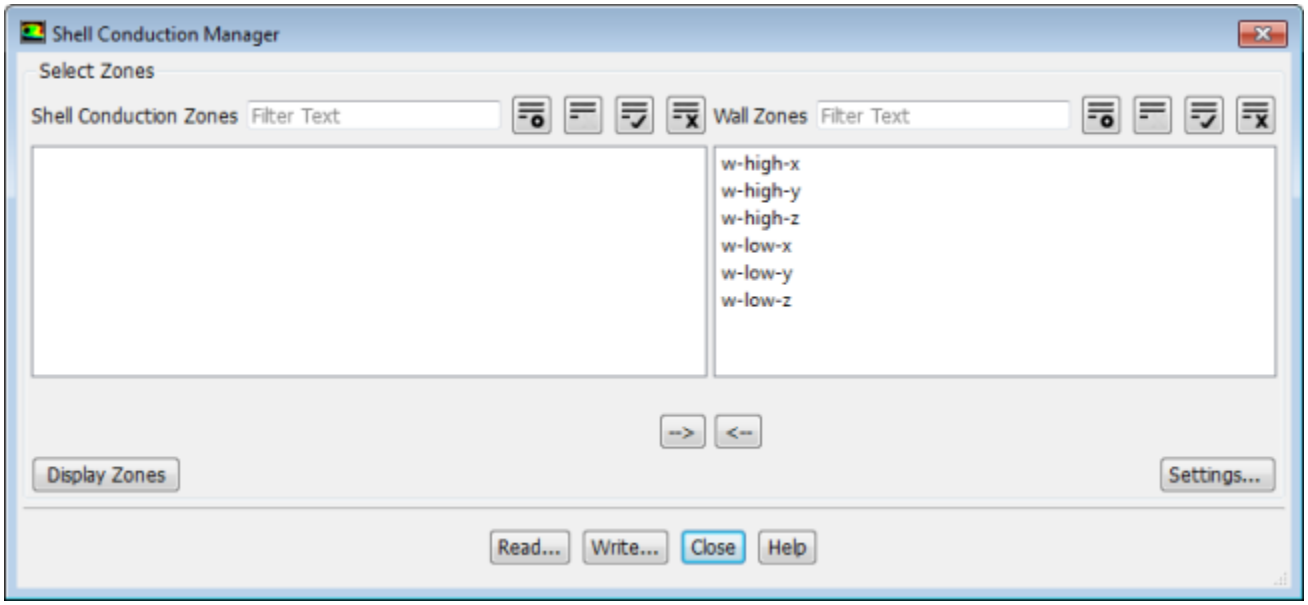
- display any wall zone
- enable or disable shell conduction for a wall
- define the settings for shell conduction walls or layers, such as thickness, material, and heat generation rate

Note that you can still enable shell conduction for a wall and define the related settings using the **Wall** dialog box, as described in Shell Conduction (p. 376). However, the **Shell Conduction Manager** dialog box provides you with an alternative to do such activities from a single dialog box for all the walls, instead of visiting the individual **Wall** boundary condition dialog boxes.

Setting Up Physics → Model Specific → Shell Conduction...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.7: The Shell Conduction Manager Dialog Box



To manage shell conduction using the **Shell Conduction Manager** dialog box, perform the following steps:

1. (optional) If you have previously generated a CSV file that contains shell conduction settings for the layers of the walls, you can read it by clicking **Read...** at the bottom of the **Shell Conduction Manager** dialog box and using the dialog box that opens; otherwise, you should proceed to the steps that follow.

   Using a CSV file can be helpful when you have a large number of layers and walls. It is not necessary to create the CSV file from nothing, as you can create a simplified CSV file with sample values using the **Write...** button (as described in step 5.), and then revise the settings using a spreadsheet program. See Shell Conduction Settings File Format (p. 2868) for details about the format of the CSV file.

2. Use the -> and <- buttons to move the selected zones from one list to another, and thereby define whether they are shells. Zones with shell conduction enabled are listed under **Shell Conduction Zones** and those without shell conduction are listed under **Wall Zones**. In essence, the -> button disables shell conduction and the <- button enables shell conduction.

3. Click the **Display Zones** button to display the selected walls in the graphics window. Note that you can select walls with or without shell conduction. The zones will be displayed with different colors depending on the option selected in the **Mesh Colors** dialog box, which is accessible from the **Mesh Display** dialog box.

4. Define settings for all of the shells by performing the following steps:

   a. Select walls from the **Shell Conduction Zones** for which you want to define the same settings.

   b. Click the **Settings...** button to open the **Shell Conduction Layers** dialog box (Figure 12.8: Shell Conduction Layers Dialog Box (p. 842)). There you can specify the number of layers, and then define the thickness, material, and heat generation rate for each layer. Note that you have the option of defining the heat generation rate using a user-defined function (UDF) that utilizes the

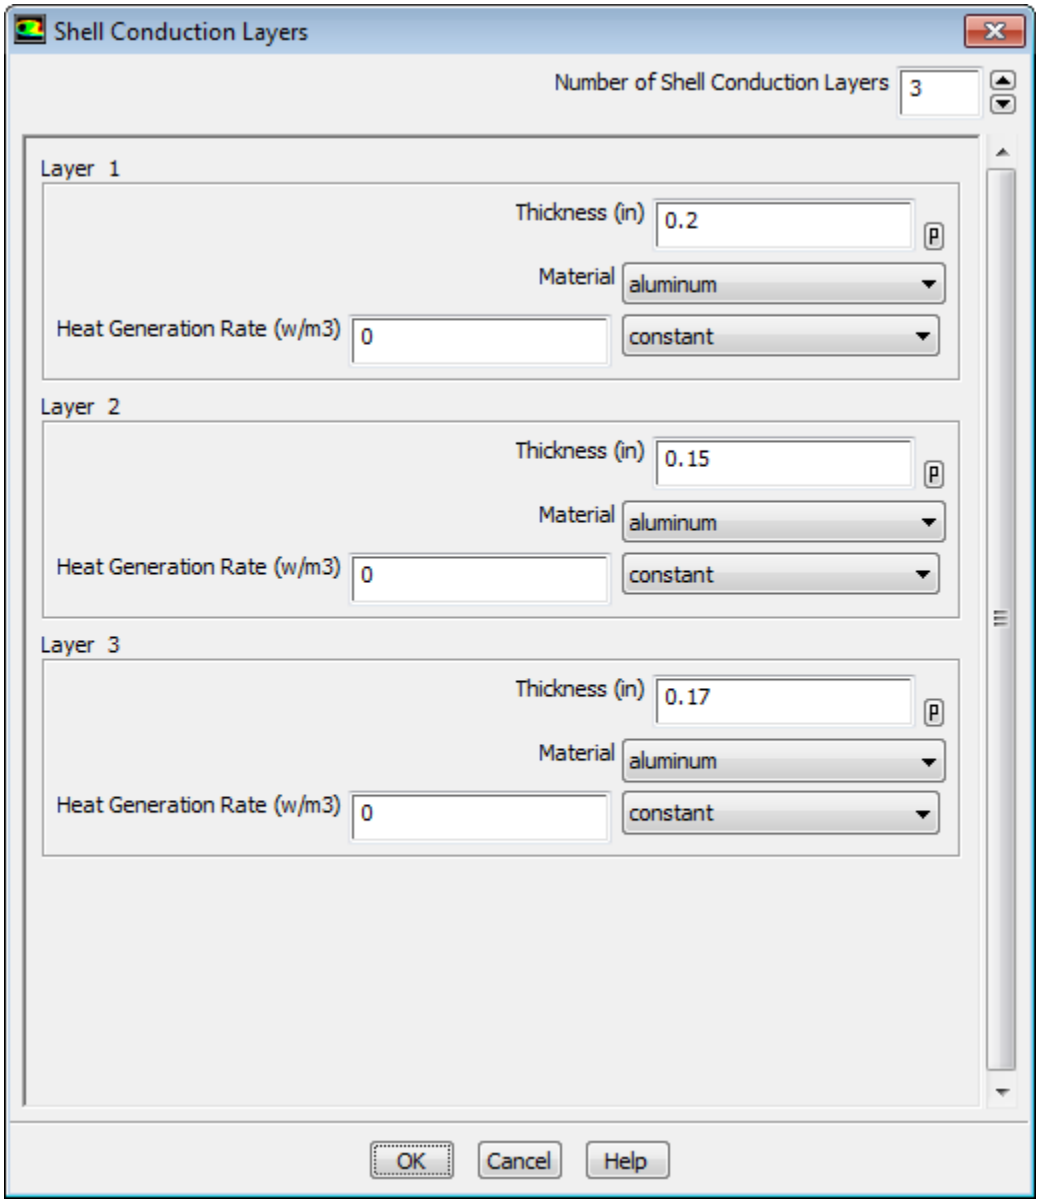
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DEFINE_PROFILE macro; for more information on creating and using user-defined functions, see the Fluent Customization Manual.

Important

You must specify a nonzero-thickness for every layer.

Figure 12.8: Shell Conduction Layers Dialog Box



c. Click **OK** to save your settings for the selected walls and close the **Shell Conduction Layers** dialog box.

5. If you want to save all of the settings you specified using the **Shell Conduction Manager** dialog box as a CSV file, click **Write...** and specify a name in the dialog box that opens. You can edit the shell conduction settings in this CSV file using a spreadsheet program, and then read it in this or a separate case file, as described in step 1. Note that information will not be written for any wall that defines the heat generation rate using a UDF.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that you have the option of disabling shell conduction in every wall with a single action, by using the following text command. This capability is available in both serial and parallel mode.

`define` → `boundary-conditions` → `modify-zones` → `delete-all-shells`

12.2.5.5. Initializing Shells

Shell zones can be patched using the **Patch** dialog box, as described in Patching Values in Selected Cells (p. 1593).

Solution → **Initialization** **Patch...**

12.2.5.6. Locking the Temperature for Shells

You can lock (or "freeze") the temperature values for all the cells in shells and solid zones (including those to which you have a hooked an energy source through a UDF) by using the `solve/set/lock-solid-temperature?` text command, as described in Locking the Temperature for Solid and Shell Zones (p. 297).

12.2.5.7. Postprocessing Shells

In order to facilitate the postprocessing of shells, surfaces (referred to as "shell surfaces") are created at the interface of adjacent layers, as well as at the layer surface that is furthest from the wall surface. Note that shell surfaces are not created on the sides of the shell zones or in the interior of the layers. The shell surfaces can then be selected from the **Surfaces** list available in a variety of dialog boxes (for example, the **Contours** dialog box, the **Surface Report Definition** dialog box, and the **Solution XY Plot** dialog box) in the same way as the surfaces for the wall and (for two-sided walls) the shadow wall. When visualized in the graphics display window, these shell surfaces will be coincident with the wall they are associated with.

The default naming convention for these shell surfaces is <*wall_name*>**-**<*c0*>**:**<*c1*>, where:

- <*wall_name*> is the name of the wall on which the layers have been grown.
- <*c0*> is the rank of the layer on the c0 side of the interface (that is, the layer closest to the wall surface).
- <*c1*> is the rank of the layer on the c1 side of the interface (that is, the layer furthest from the wall surface). Note that the layer surface that is furthest from the wall surface does not have a layer on the c1 side, and so a different convention is used: for boundary walls, <*c1*> is set to **external**; for two-sided walls, <*c1*> is set to the name of the fluid / solid adjacent to the shadow wall.

You have the ability to rename the shell surfaces, if you want. The following figures illustrate the default naming convention, where the wall/shadow surfaces are displayed in red and the shell surfaces are displayed in black.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.9: Shell Surface Names for a Boundary Wall

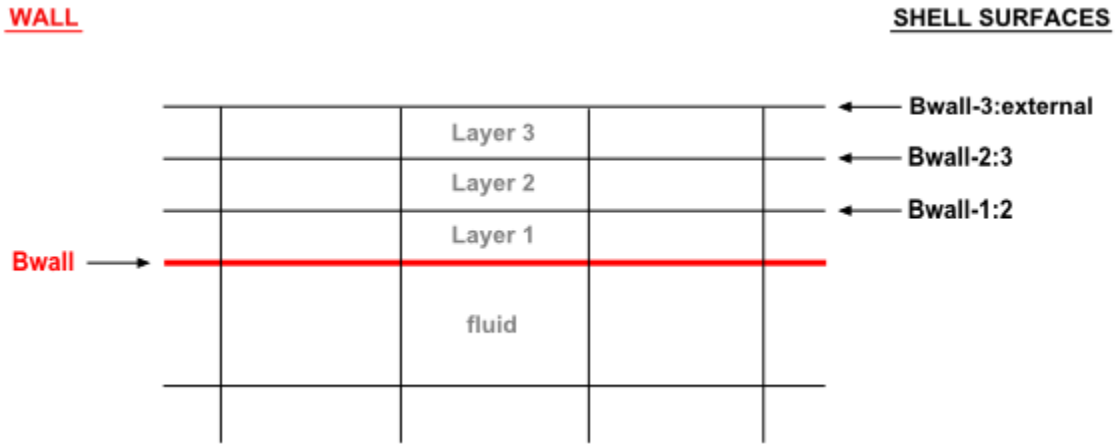


Figure 12.10: Shell Surface Names for a Two-Sided Wall

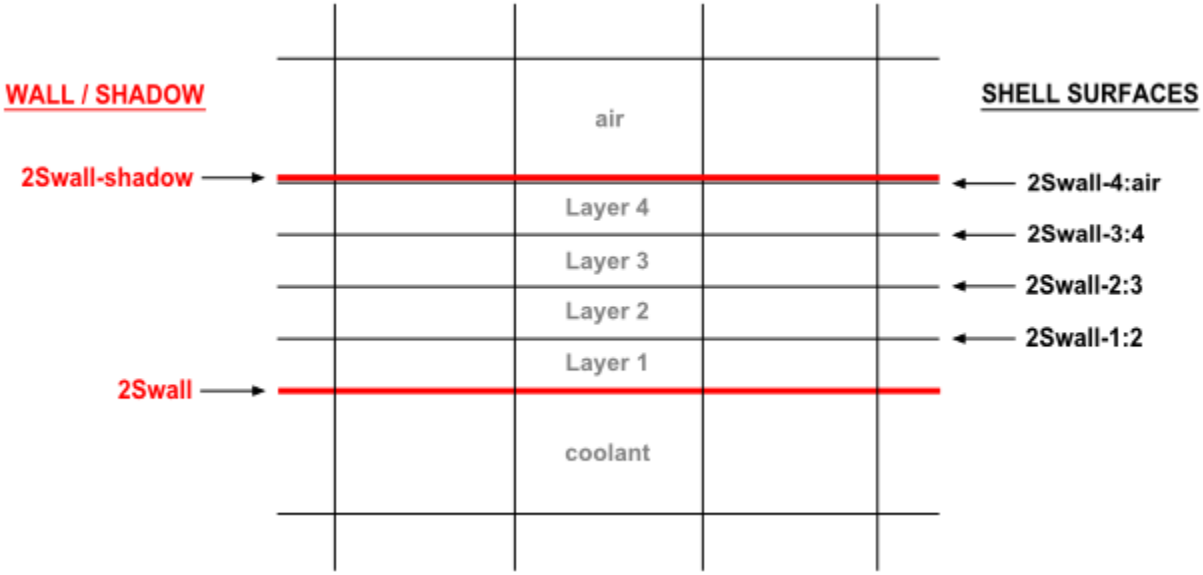


You can use the walls, shadow walls, and shell surfaces to display the temperature of the interfaces and adjacent cells. The **Temperature...** category provides two options: the temperature of the cell on the c0 side of the surface is stored as **Static Temperature**; and the temperature of the surface itself is stored as **Wall Temperature**. If a more detailed analysis of the solid zone and surfaces is required, then you should consider creating layers of solid cells in your meshing application.

The following examples illustrate how to postprocess the surfaces shown in Figure 12.9: Shell Surface Names for a Boundary Wall (p. 844):

- The **Static Temperature** and **Wall Temperature** of **Bwall** will provide the temperature of the fluid cells adjacent to **Bwall** and the temperature of the **Bwall** surface itself, respectively.
- The **Static Temperature** and **Wall Temperature** of **Bwall-1:2** will provide the temperature of the cells of **Layer 1** and the temperature of the interface between **Layer 1** and **Layer 2** (that is, the **Bwall-1:2** shell surface), respectively.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Static Temperature** and **Wall Temperature** of **Bwall-3:external** will provide the temperature of the cells of **Layer 3** and the temperature of the layer surface that is furthest from the wall surface (that is, the **Bwall-3:external** shell surface), respectively.

The following examples illustrate how to postprocess the surfaces shown in Figure 12.10: Shell Surface Names for a Two-Sided Wall (p. 844):

- The **Static Temperature** and **Wall Temperature** of **2Swall-4:air** will provide the temperature of the cells of **Layer 4** and the temperature of the interface between **Layer 4** and the shadow wall (that is, the **2Swall-4:air** shell surface), respectively.

- The **Static Temperature** and **Wall Temperature** of **2Swall-shadow** will provide the temperature of the air cells adjacent to **2Swall-shadow** and the temperature of the shadow wall, respectively.

When postprocessing shells, note the following limitations:

- You should not enable **Node Values** when postprocessing any surfaces associated with shells (that is, the wall, shadow wall, or shell surfaces). The layers share nodes at the edges, and thus the averaging at such nodes is erroneous.

- You cannot postprocess shells in ANSYS CFD-Post, as shell surfaces are not supported.

12.3. Modeling Radiation

Information about radiation modeling is presented in the following sections:

12.3.1. Using the Radiation Models
12.3.2. Setting Up the P-1 Model with Non-Gray Radiation
12.3.3. Setting Up the DTRM
12.3.4. Setting Up the S2S Model
12.3.5. Setting Up the DO Model
12.3.6. Setting Up the MC Model
12.3.7. Defining Material Properties for Radiation
12.3.8. Defining Boundary Conditions for Radiation
12.3.9. Solution Strategies for Radiation Modeling
12.3.10. Postprocessing Radiation Quantities
12.3.11. Solar Load Model

For theoretical information about the radiation models in ANSYS Fluent, refer to Modeling Radiation in the Theory Guide.

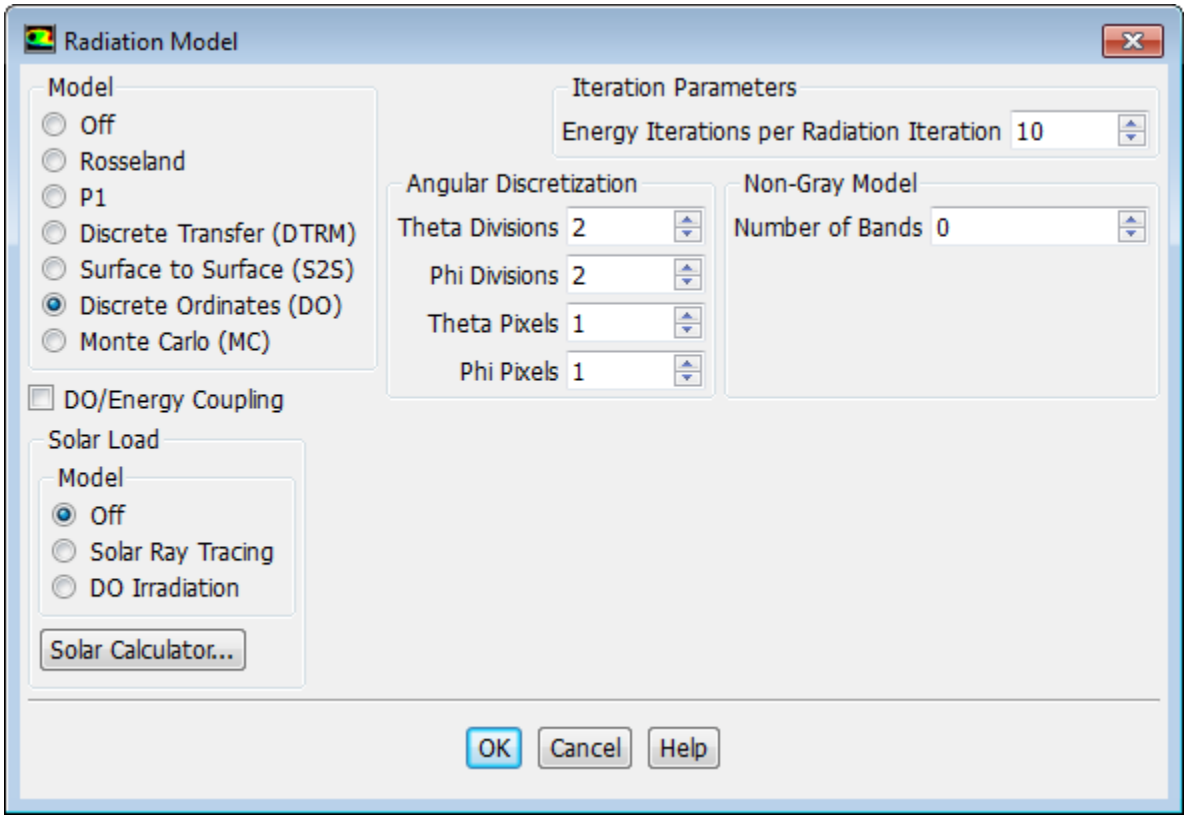
12.3.1. Using the Radiation Models

The procedure for setting up and solving a radiation problem is outlined below, and described in detail in referenced sections. Steps that are relevant only for a particular radiation model are noted as such. The steps that are pertinent to radiation modeling, are shown here. For information about inputs related to other models that you are using in conjunction with radiation, see the appropriate sections for those models.

1. Enable radiative heat transfer by selecting a radiation model (**Rosseland**, **P1**, **Discrete Transfer (DTRM)**, **Surface to Surface (S2S)**, **Discrete Ordinates**, or **Monte Carlo (MC)**) under **Model** in the **Radiation Model** dialog box (Figure 12.11: The Radiation Model Dialog Box (DO Model) (p. 846)).

   Setup → **Models** → **Radiation** → **Edit...**

Figure 12.11: The Radiation Model Dialog Box (DO Model)



Important

The **Rosseland** model can be used only with the pressure-based solver.

Note that when the P-1, the DTRM, the S2S, DO, or MC model is enabled, the **Radiation Model** dialog box expands to show additional parameters. These parameters will not appear if you select the Rosseland model. If you are running a 3D case, you will have the added option of using the solar load model. The solar load options will be displayed in the dialog box, below the radiation model settings.

When the radiation model is active, the radiation fluxes will be included in the solution of the energy equation at each iteration. If you set up a problem with the radiation model turned on, and you then decide to turn it off completely, you must select the **Off** button in the **Radiation Model** dialog box.

Note that when you enable a radiation model, ANSYS Fluent will automatically enable the energy equation so that step is not needed.

2. Set the appropriate radiation parameters.

   a. If you are modeling non-gray radiation using the P-1 model, define the non-gray radiation parameters as described in Setting Up the P-1 Model with Non-Gray Radiation (p. 847).

   b. If you are using the DTRM, define the ray tracing as described in Setting Up the DTRM (p. 848).

   c. If you are using the S2S model, define the surface clusters and view factors settings and compute or read the view factors as described in Setting Up the S2S Model (p. 851).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. If you are using the DO model, choose **DO/Energy Coupling** if desired, define the angular discretization as described in Setting Up the DO Model (p. 864) and, if relevant, define the non-gray radiation parameters as described in Defining Non-Gray Radiation for the DO Model (p. 865).

e. If you are using the MC model, specify the **Target Number of Histories** as described in Setting Up the MC Model (p. 867) and, if relevant, similar to when using the DO model, define the non-gray radiation parameters as described in Defining Non-Gray Radiation for the DO Model (p. 865).

3. Define the material properties as described in Defining Material Properties for Radiation (p. 868).

4. Define the boundary conditions as described in Defining Boundary Conditions for Radiation (p. 869). If your model contains a semi-transparent medium, see the information below on setting up semi-transparent media.

5. Set the parameters that control the solution (DTRM, DO, MC, S2S, and P-1 only) as described in Solution Strategies for Radiation Modeling (p. 878).

6. Run the solution as described in Running the Calculation (p. 880).

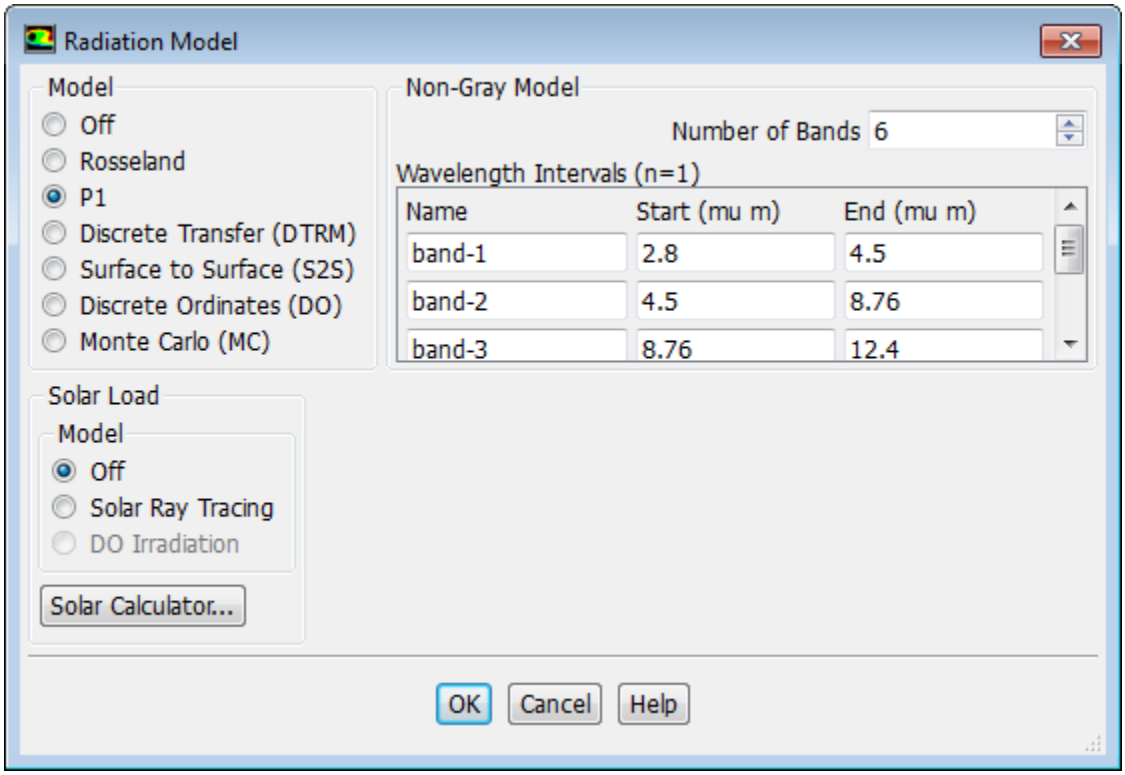
7. Postprocess the results as described in Postprocessing Radiation Quantities (p. 882).

12.3.2. Setting Up the P-1 Model with Non-Gray Radiation

If you want to model non-gray radiation using the P-1 model, you can specify the **Number of Bands** under **Non-Gray Model** in the expanded **Radiation Model** dialog box (Figure 12.12: The Radiation Model Dialog Box (Non-Gray P-1 Model) (p. 848)). By default, the **Number of Bands** is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases directly with the number of bands, you should try to minimize the number of bands used. When a nonzero **Number of Bands** is specified, the **Radiation Model** dialog box will expand once again to show the **Wavelength Intervals**. For each wavelength band, you can specify a **Name**, as well as the **Start** and **End** wavelength of the band in μm. Note that the wavelength bands are specified for vacuum (n=1). For more information about non-gray radiation calculations, see Defining Non-Gray Radiation for the DO Model (p. 865).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.12: The Radiation Model Dialog Box (Non-Gray P-1 Model)



ANSYS Fluent allows you to use a user-defined function (UDF) to modify the emissivity weighting factor $F\left(0\rightarrow n\lambda_2 T\right)-F\left(0\rightarrow n\lambda_1 T\right)$ (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of the radiative transfer equation for the non-gray model, as shown in Equation 5.25 in the Theory Guide. For more information, see the Fluent Customization Manual.

12.3.3. Setting Up the DTRM

For information about setting up the DTRM, see the following sections:

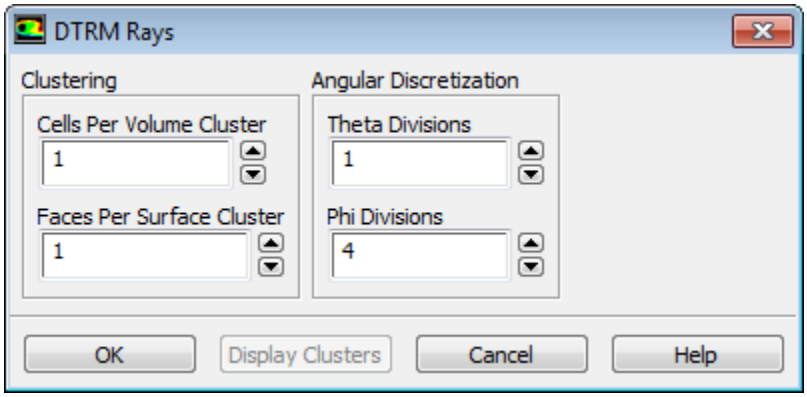
12.3.3.1. Defining the Rays
12.3.3.2. Controlling the Clusters
12.3.3.3. Controlling the Rays
12.3.3.4. Writing and Reading the DTRM Ray File
12.3.3.5. Displaying the Clusters

12.3.3.1. Defining the Rays

When you select the **Discrete Transfer** model and click **OK** in the **Radiation Model** dialog box, the **DTRM Rays** dialog box (Figure 12.13: The DTRM Rays Dialog Box (p. 849)) will open automatically. If you need to modify the current settings later in the problem setup or solution procedure, you can open this dialog box by clicking **DTRM Rays...** in the **Setting Up Physics** ribbon tab (**Model Specific** group box).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.13: The DTRM Rays Dialog Box



In this dialog box you will set parameters for and create the rays and clusters discussed in The DTRM Equations in the Theory Guide.

The procedure is as follows:

1. To control the number of radiating surfaces and absorbing cells, set the **Cells Per Volume Cluster** and **Faces Per Surface Cluster**. (See the explanation below.)

2. To control the number of rays being traced, set the number of **Theta Divisions** and **Phi Divisions**. (Guidelines are provided below.)

3. When you click **OK** in the **DTRM Rays** dialog box, The Select File Dialog Box (p. 19) will open prompting you for the name of the "ray file". After you have specified the filename and chosen whether to write a binary ray file, ANSYS Fluent will write the ray file and then read it afterward. During the write process the status of the DTRM ray tracing will be reported in the ANSYS Fluent console. For example:

   ```
   Completed 25% tracing of DTRM rays

   Completed 50% tracing of DTRM rays

   Completed 75% tracing of DTRM rays

   Completed 100 % tracing of DTRM rays
   ```

   See following sections for details on **DTRM Rays** dialog box inputs.

Important

If you cancel the **DTRM Rays** dialog box without writing and reading the ray file, the DTRM will be disabled.

12.3.3.2. Controlling the Clusters

Your inputs for **Cells Per Volume Cluster** and **Faces Per Surface Cluster** will control the number of radiating surfaces and absorbing cells. By default, each is set to 1, so the number of surface clusters (radiating surfaces) will be the number of boundary faces, and the number of volume clusters (absorbing cells) will be the number of cells in the domain. For small 2D problems, these are acceptable numbers,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

but for larger problems you will want to reduce the number of surface and/or volume clusters in order to reduce the ray-tracing expense. See Clustering in the Theory Guide for details about clustering.

Note

- Only zones attached to fluid cell zones are used for creating surface clusters.
- **Faces Per Surface Cluster** (FPSC) is indicative of the actual reduction factor except when the surfaces are planar. The surface clustering algorithm uses other criteria (angle between faces, and so on) to ensure the clusters are nearly planar, so it is possible that there will be no further reduction in the total number of clusters beyond a certain value of FPSC.

12.3.3.3. Controlling the Rays

Your inputs for **Theta Divisions** and **Phi Divisions** will control the number of rays being traced from each surface cluster (radiating surface).

Theta Divisions defines the number of discrete divisions in the angle θ used to define the solid angle about a point P on a surface. The solid angle is defined as θ varies from 0 to 90 degrees (in the Theory Guide), and the default setting of 1 for the number of discrete settings implies that there will be one ray traced from the surface.

Phi Divisions defines the number of discrete divisions in the angle ϕ used to define the solid angle about a point P on a surface. The solid angle is defined as ϕ varies from 0 to 360 degrees (Figure 5.2: Angles θ and ϕ Defining the Hemispherical Solid Angle About a Point P in the Theory Guide). The default setting of 4 implies that each ray traced from the surface will be located at a 90° angle, and in combination with the default setting for **Theta Divisions**, above, implies that 4 rays will be traced from each surface control volume. In many cases, it is recommended that you at least double the number of divisions in θ and ϕ.

12.3.3.4. Writing and Reading the DTRM Ray File

After you have activated the DTRM and defined all of the parameters controlling the ray tracing, you must create a ray file, which will be read back in and used during the radiation calculation. The ray file contains a description of the ray traces (for example, path lengths, cells traversed by each ray). This information is stored in the ray file, instead of being recomputed, in order to speed up the calculation process.

By default, a binary ray file will be written. You can also create text (formatted) ray files by turning off the **Write Binary Files** option in The Select File Dialog Box (p. 19).

Important

Do not write or read a compressed ray file, because ANSYS Fluent will not be able to access the ray tracing information properly from a compressed ray file.

The ray filename must be specified to ANSYS Fluent only once. Thereafter, the filename is stored in your case file and the ray file will be automatically read into ANSYS Fluent whenever the case file is read. ANSYS Fluent will remind you that it is reading the ray file after it finishes reading the rest of the case file by reporting its progress in the console.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the ray filename stored in your case file may not contain the full name of the directory in which the ray file exists. The full directory name will be stored in the case file only if you initially read the ray file through the GUI (or if you typed in the directory name along with the filename when using the text interface). In the event that the full directory name is absent, the automatic reading of the ray file may fail (since ANSYS Fluent does not know in which directory to look for the file), and you will need to manually specify the ray file, using the **File/Read/DTRM Rays...** ribbon tab item. The safest approaches are to use the GUI when you first read the ray file or to supply the full directory name when using the text interface.

Important

You must recreate the ray file whenever you do anything that changes the mesh, such as:

- change the type of a boundary zone
- adapt the mesh
- scale the mesh

You can open the **DTRM Rays** dialog box directly by clicking **DTRM Rays...** in the **Setting Up Physics** ribbon tab (**Model Specific** group box).

12.3.3.5. Displaying the Clusters

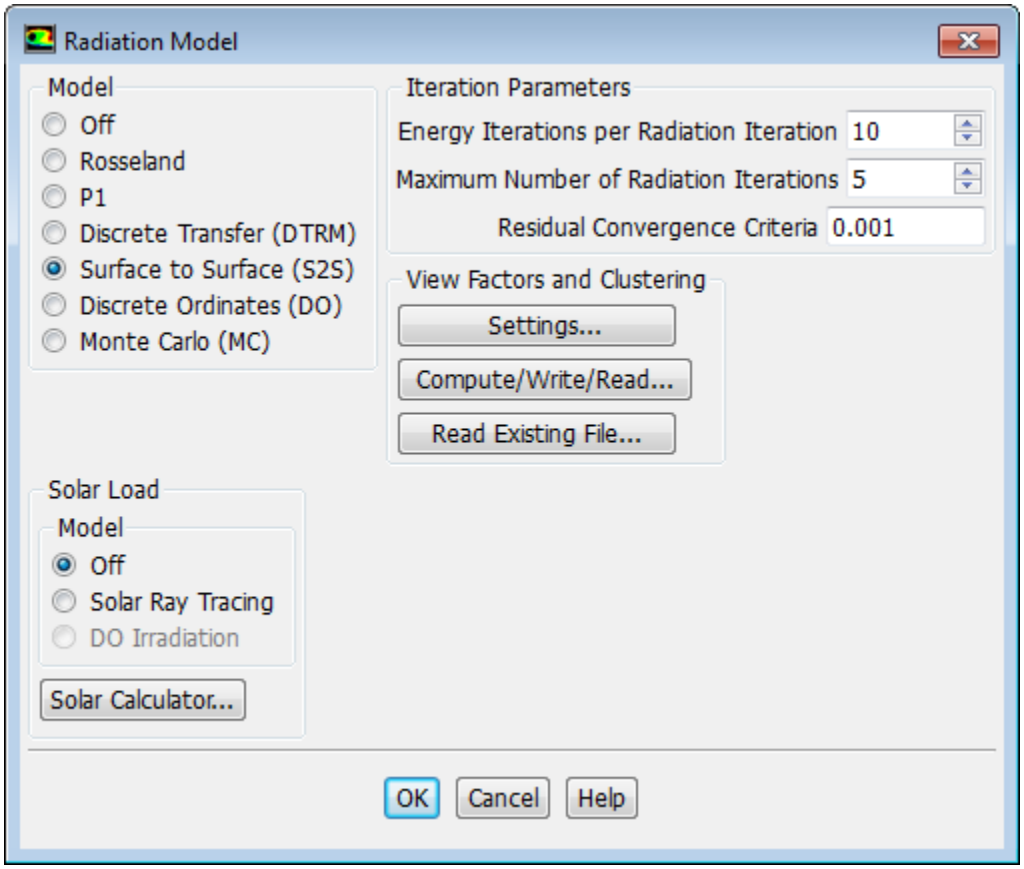
Once a ray file has been created or read in manually, you can click the **Display Clusters** button in the **DTRM Rays** dialog box to graphically display the clusters in the domain. See Displaying Rays and Clusters for the DTRM (p. 883) for additional information about displaying rays and clusters.

12.3.4. Setting Up the S2S Model

When you select the **Surface to Surface (S2S)** model, the **Radiation Model** dialog box will expand to show additional parameters (see Figure 12.14: The Radiation Model Dialog Box (S2S Model) (p. 852)). In these additional group boxes, you will set the solution parameters (see S2S Solution Parameters (p. 880) for further details), access the view factors and clustering settings, and compute the view factors for your problem or read previously computed view factors into ANSYS Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.14: The Radiation Model Dialog Box (S2S Model)



The S2S radiation model is very expensive in terms of computation effort and memory requirements when there are a large number of radiating surfaces. You can reduce the number of radiating surfaces by grouping faces together to form surface clusters. The surface cluster information (coordinates and connectivity of the nodes, surface cluster IDs) is used by ANSYS Fluent in the radiosity calculations and to compute the view factors.

Important

- You must recreate the surface cluster information whenever you do anything that changes the mesh, such as:
  - change the type of a boundary zone
  - scale the mesh

  Note that you do *not* need to recalculate view factors after shell conduction at any wall has been enabled or disabled (see Thermal Boundary Conditions at Walls (p. 370) for more information about shell conduction). However, enabling or disabling shell conduction in the parallel version of Fluent does cause a migration of cells and hence a change in the partition. Whenever there is cell migration, the previously read view factor file is no longer valid, and the view factor file must be read again using either the **Read Existing File** button in the **Radiation Model** dialog box or the **File/Read/View Factors...** ribbon tab item.

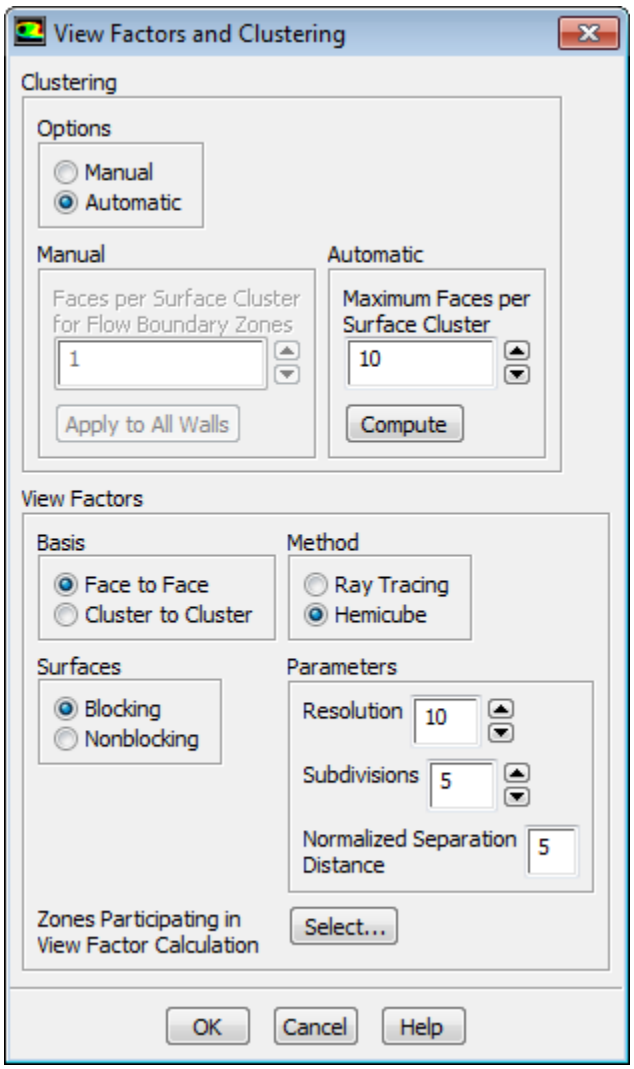
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ANSYS Fluent will warn you to recreate the cluster/view factor file if a boundary zone has been changed from a wall to an internal wall (or vice versa), or if a boundary zone has been merged, separated, or fused.

12.3.4.1. View Factors and Clustering Settings

You can use the **View Factors and Clustering** dialog box (Figure 12.15: The View Factors and Clustering Dialog Box (p. 853)) to define how the surface clusters are formed and how the view factors are calculated for the S2S model. To open this dialog box, click **Settings...** in the **View Factors and Clustering** group box in the Radiation Model Dialog Box (p. 2190) (Figure 12.14: The Radiation Model Dialog Box (S2S Model) (p. 852)) or use the **File/Write/Surface Clusters...** ribbon tab item.

Figure 12.15: The View Factors and Clustering Dialog Box



12.3.4.1.1. Forming Surface Clusters

You can set the number of faces per surface cluster (FPSC) for each flow boundary (that is, exhaust fan, inlet vent, intake fan, outlet vent, mass-flow inlet, mass-flow outlet, pressure far-field, pressure inlet, pressure outlet, outflow, and velocity inlet boundary) and wall that is adjacent to a fluid zone; in this way, you can control the number of radiating surfaces and (if you select **Cluster to Cluster** for **Basis**)

view factor surfaces. By default, the FPSC value is set to 1 everywhere, so the number of surface clusters (radiating/view factor surfaces) will be equal to the number of boundary faces. For small 2D problems, this is an acceptable number. For larger problems, you may want to reduce the number of surface clusters (that is, increase the FPSC) to reduce both the size of the view factor file and the memory requirement. Such a reduction in the number of clusters, however, comes at the cost of some accuracy. Note that for a thermally coupled mesh interface (that is, a fluid-fluid interface with **Coupled Wall** enabled, or an interface involving a solid zone), the FPSC is always set to 1. See Clustering in the Theory Guide for details about clustering.

Important

If you plan to use the cluster to cluster basis for the view factor calculation, be sure that the FPSC values are appropriate for both the radiosity calculation and the view factors.

Note that during the creation of a cluster on a non-conformal interface, its parent thread is taken into the consideration; it may happen that the cluster is somewhat larger than its child face, which may lead some inaccuracy in the flux calculation.

The **Clustering** group box in the **View Factors and Clustering** dialog box (Figure 12.15: The View Factors and Clustering Dialog Box (p. 853)) provides two methods for revising the default FPSC values:

- manual
- automatic

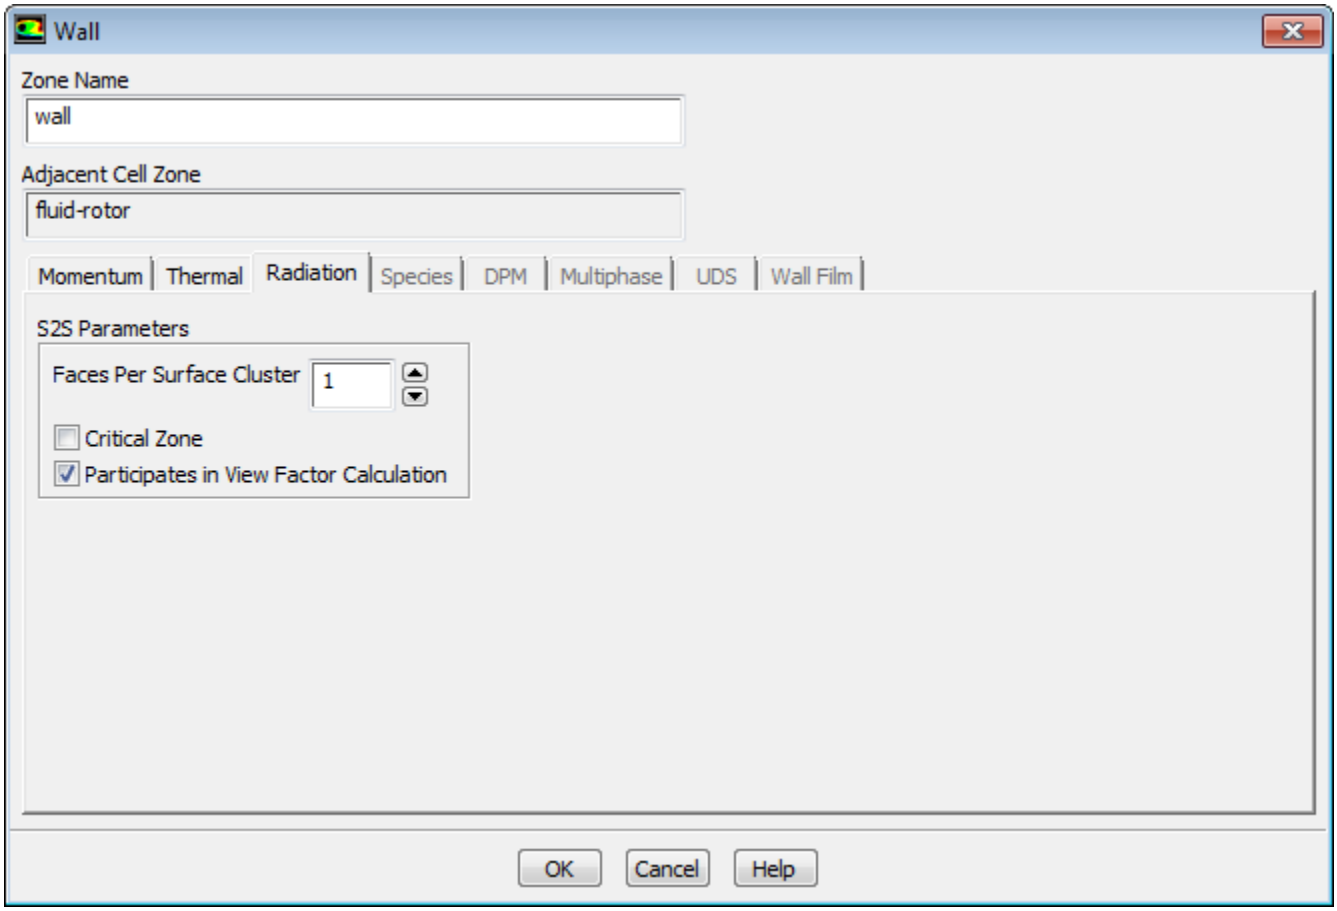
If you select **Manual** in the **Options** group box, you can specify an FPSC value for all flow boundaries in the **Faces per Surface Cluster for Flow Boundary Zones** number-entry box in the **Manual** group box. If you then click **Apply to All Walls**, you will apply this value to all wall zones that are adjacent to fluid zones as well. For a wall that requires a different FPSC value (that is, you may want a lower value for walls in critical areas, and higher values in non-critical areas), you will need to open the boundary condition dialog box (Figure 12.16: The Wall Dialog Box (p. 855)) for that particular wall and modify the **Faces Per Surface Cluster** in the **S2S Parameters** group box of the **Radiation** tab. Note that the **Radiation** tab also allows you to specify whether the wall participates in the view factor calculation, as described in Specifying Boundary Zone Participation (p. 858).

Note

- Only zones attached to fluid cell zones are used for creating surface clusters.
- **Faces Per Surface Cluster** (FPSC) is indicative of the actual reduction factor except when the surfaces are planar. The surface clustering algorithm uses other criteria (angle between faces, and so on) to ensure the clusters are nearly planar, so it is possible that there will be no further reduction in the total number of clusters beyond a certain value of FPSC.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.16: The Wall Dialog Box



Important

The **Faces Per Surface Cluster** number-entry box will not be visible in the GUI on wall boundary zones that are attached to a solid.

Using the manual method to specify the FPSC values for walls can become very cumbersome if the model involves a large number of radiating faces, which is typically the case in underhood models. In such circumstances, it is recommended that you use the automatic clustering method instead. In this method, different FPSC values are assigned to the walls automatically, based on the distance of the walls from and the FPSC values of the walls that are defined as critical. The steps you will need to take are as follows:

1. Select **Automatic** from the **Options** list in the **View Factors and Clustering** dialog box.
2. For each wall that you deem critical, perform the following actions in the **Wall** dialog box (Figure 12.16: The Wall Dialog Box (p. 855)):
   a. Click the **Radiation** tab.
   b. Enter an appropriate value for **Faces Per Surface Cluster** in the **S2S Parameters** group box.
   c. Enable the **Critical Zone** option.
   d. Click **OK** to close the **Wall** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Enter the **Maximum Faces per Surface Cluster** value in the **View Factors and Clustering** dialog box and click the **Compute** button. ANSYS Fluent will automatically calculate and update the **Faces Per Surface Cluster** values for all **Wall** dialog boxes adjacent to fluid zones that do not have **Critical Zone** enabled, without computing the clusters.

4. You can check the automatically assigned FPSC values by opening the boundary condition dialog box of any non-critical wall of interest and examining the value for **Faces Per Surface Cluster** in the **S2S Parameters** group box of **Radiation** tab. You can manually modify the value for **Faces Per Surface Cluster** as necessary.

12.3.4.1.1.1. Setting the Split Angle for Clusters

Whether you set the FPSC value manually or automatically, you have the option of modifying the cutoff or "split" angle between adjacent face normals for the purpose of controlling surface clustering. The split angle sets the limit for which adjacent faces are clustered. A smaller split angle allows for a better representation of the view factor. By default, no surface cluster will contain any face that has a face normal greater than 20°. To modify the value of this parameter, you can use the `split-angle` text command:

`define` → `models` → `radiation` → `s2s-parameters` → `split-angle`

or

`file` → `write-surface-clusters` → `split-angle`

12.3.4.1.2. Setting Up the View Factor Calculation

You can control many aspects of how the view factors are calculated for your S2S model: how surfaces are defined; the computational method and related parameters; whether surface blocking will be accounted for; and which boundary zones will participate in the calculation. All of these controls are available in the **View Factors** group box in the **View Factors and Clustering** dialog box (Figure 12.15: The View Factors and Clustering Dialog Box (p. 853)), and are described in the sections that follow.

12.3.4.1.2.1. Selecting the Basis for Computing View Factors

ANSYS Fluent allows two ways to define the surfaces used for the view factor calculation, as described in Clustering and View Factors in the Theory Guide. If you want the surfaces to be the boundary faces of the mesh, select **Face to Face** for **Basis** in the **View Factor** group box of the **View Factors and Clustering** dialog box. This is the default selection.

Alternatively, you can select **Cluster to Cluster** for **Basis**, in order to reduce the computational expense and storage requirements. In this case, the surfaces used to calculate the view factors are the clusters defined by the settings in the **Cluster** group box of the **View Factors and Clustering** dialog box. The reduction in computational time will be proportional to the number of surface clusters used in the view factor calculation. The trade-offs of using the cluster to cluster basis for the calculation are that the accuracy may decrease, and the following limitations apply:

- The mesh must be 3D.
- You cannot subdivide the faces as part of the hemicube method parameters, which can cause the view factors to be overestimated.
- Polyhedral meshes are restricted to 1 face per surface cluster.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- When using the cluster to cluster basis with non-conformal interfaces, the **Faces Per Surface Cluster** will be limited to one, giving no advantage to the cluster to cluster basis.

12.3.4.1.2.2. Selecting the Method for Computing View Factors

ANSYS Fluent provides two methods for computing view factors: the ray tracing method (which is selected by default) and the hemicube method. The following limitations apply:

- The hemicube method is available only for 3D and axisymmetric cases.
- The hemicube method should not be used when any of the zones are defined as periodic or symmetry boundaries, as these types are not currently supported.
- For the ray tracing method, when running in distributed parallel mode, the working directory must be shared across all machines.

The hemicube method uses a differential area-to-area method and calculates the view factors on a row-by-row basis. The view factors calculated from the differential areas are summed to provide the view factor for the whole surface. This method originated from the use of the radiosity approach in the field of computer graphics [22] (p. 2888).

To use the hemicube method to compute the view factors, select **Hemicube** from the **Method** list in the **View Factors and Clustering** dialog box. It is recommended that you use the hemicube method for large, complex models with few obstructing surfaces between the radiating surfaces.

The hemicube method is based upon three assumptions about the geometry of the surfaces: aliasing, visibility, and proximity. To validate these assumptions, you can specify three different hemicube parameters, which can help you obtain better accuracy in calculating view factors. In most cases, however, the default settings will be sufficient.

- Aliasing—The true projection of each visible face onto the hemicube can be accurately accounted for by using a finite-resolution hemicube. As described previously, the faces are projected onto a hemicube. Because of the finite resolution of the hemicube, the projected areas and resulting view factors may be overestimated or underestimated. Aliasing effects can be reduced by increasing the value of the **Resolution** of the hemicube in the **Parameters** group box.
- Visibility—The visibility between any two faces does not change. In some cases, face i has a complete view of face k from its centroid, but some other face j occludes much of face k from face i. In such a case, the hemicube method will overestimate the view factor between face i and face k calculated from the centroid of face i. This error can be reduced by subdividing face i into smaller subfaces. You can specify the number of subfaces by entering a value for **Subdivisions** in the **Parameters** group box. Note that you cannot subdivide the faces when **Cluster to Cluster** is selected for **Basis**.
- Proximity—The distance between faces is great compared to the effective diameter of the faces. The proximity assumption is violated whenever faces are close together in comparison to their effective diameter or are adjacent to one another. In such cases, the distances between the centroid of one face and all points on the other face vary greatly. Since the view factor dependence on distance is nonlinear, the result is a poor estimate of the view factor.

  In the **Parameters** group box, you can set a limit for the **Normalized Separation Distance**, which is the ratio of the minimum face separation to the effective diameter of the face. If the computed normalized separation distance is less than the specified value, the face will then be divided into a number of subfaces until the normalized distances of the subfaces are greater than the specified

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

value. Alternatively, you can specify the number of subfaces to create for such faces by entering a value for **Subdivisions**.

While the hemicube method projects radiating surfaces onto a hemicube, the ray tracing method instead traces rays through the centers of every hemicube face to determine which surfaces are visible through that face. Note that the ray tracing method does not subdivide the faces (as can be done when using the hemicube method by setting the **Subdivisions** or **Normalized Separation Distance** parameters), and so the view factors may be less accurate than those calculated using the hemicube method for surfaces that have a normalized separation distance less than 5.

To use the ray tracing method to compute the view factors, select **Ray Tracing** from the **Method** list in the **View Factors and Clustering** dialog box. You can adjust the value of the **Resolution** in the **Parameters** group box in order to reduce the impact of aliasing effects, as described previously.

12.3.4.1.2.3. Accounting for Blocking Surfaces

View factor calculations depend on the geometric orientations of surface pairs with respect to each other. Two situations may be encountered when examining surface pairs:

- If there is no obstruction between the surface pairs under consideration, then they are referred to as "non-blocking" surfaces.
- If there is another surface blocking the views between the surfaces under consideration, then they are referred to as "blocking" surfaces. Blocking will change the view factors between the surface pairs and require additional checks to compute the correct value of the view factors.

For cases with blocking surfaces, select **Blocking** from the **Surfaces** list in the **View Factors and Clustering** dialog box. For cases with nonblocking surfaces, you can choose either **Blocking** or **Nonblocking** without affecting the accuracy. However, it is better to choose **Nonblocking** for such cases, as it takes less time to compute.

12.3.4.1.2.4. Specifying Boundary Zone Participation

You can choose to exclude walls and inlet and exit boundaries from participating in the view factor calculation. If you are unsure whether it is necessary to calculate view factors for a particular boundary zone ahead of time, it is recommended that you allow it to participate; you can always reverse this decision as part of a future calculation run.

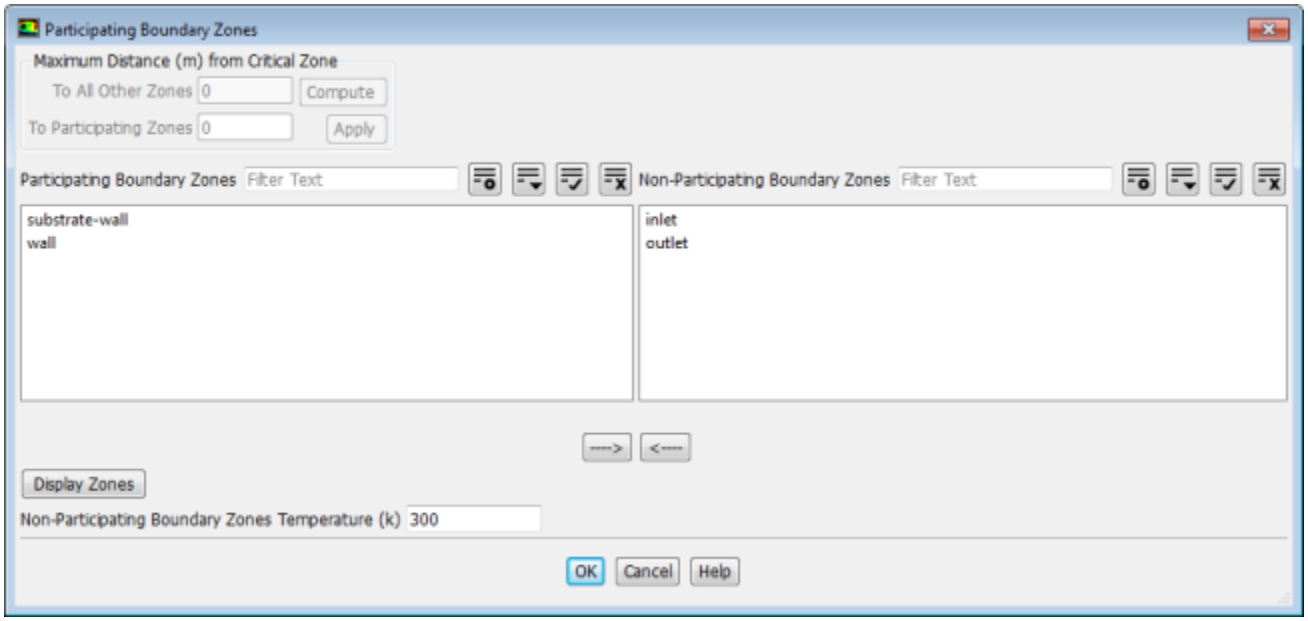
There are two ways in which you can enable/disable the participation of walls and inlet and exit boundaries in the view factor calculation. One of those ways is to use the **Participates in View Factor Calculation** option in the **Radiation** tab of the boundary condition dialog box. The other method is to use the **Participating Boundary Zones** dialog box (Figure 12.17: The Participating Boundary Zones Dialog Box (p. 859)), which is accessed by clicking the **Select...** button next to the **Zones Participating in View Factor Calculation** label in the **View Factors and Clustering** dialog box. For cases that are made up of a very large number of zones, such as underhood applications, the latter method is recommended.

Important

If you compute the view factors and then later alter which boundary zones participate in the view factor calculation, you must recompute the view factors so that the data is up to date.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.17: The Participating Boundary Zones Dialog Box



The **Participating Boundary Zones** dialog box allows you to easily specify those zones that are participating or non-participating without having to visit the boundary conditions dialog box of each zone. For cases that have a small number of boundary zones, you can simply select the zones that you do not want to participate in the view factor calculation from the **Participating Boundary Zones** list and click the arrow button that points to the right, so that the zones are moved to the **Non-Participating Boundary Zones** list; if you make an error, you can always reverse this process (that is, select a zone in the **Non-Participating Boundary Zones** list and click the arrow button that points to the left). This can be cumbersome for cases that have a large number of boundary zones, and so the following procedure is recommended instead:

1. Make sure that your clustering options (see Forming Surface Clusters (p. 853)) are appropriate for your view factor settings:

   a. Select **Automatic** from the **Options** list in the **Clustering** group box of the **View Factors and Clustering** dialog box, as this enables some GUI items in the **Participating Boundary Zones** dialog box.

   Important

   Note that if you do not want to use the **Automatic** option for the clustering, you can revert to the **Manual** option after you are done using the **Participating Boundary Zones** dialog box.

   b. Verify that the walls you specified as critical (by enabling the **Critical Zone** option in the **Radiation** tab of the boundary condition dialog box) also correspond to those that are critical for the view factor calculation. You must have specified at least one critical zone for the steps that follow.

2. Click the **Compute** button in the **Maximum Distance from Critical Zone** dialog box, to update the value displayed for **To All Other Zones**. This value represents the maximum distance between the centroids of a critical zone and a non-critical zone in the mesh; it is for information purposes only, and cannot be edited in this dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Based on the value displayed for **To All Other Zones**, enter a threshold value for **To Participating Zones**. The value you enter will specify the maximum distance allowed between the centroids of a critical zone and a zone that participates in the view factor calculation. Then click the **Apply** button to move all zones beyond this distance into the **Non-Participating Boundary Zones** list.

4. Review the zones displayed in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists. If necessary, select zones in these lists and use the arrow buttons to move them to the appropriate list, as described previously.

If at any point you want to visually identify zones displayed in the **Participating Boundary Zones** and **Non-Participating Boundary Zones** lists, select the zones and click the **Display Zones** button. Only the selected zones will be displayed in the graphics window.

If any zones are displayed in the **Non-Participating Boundary Zones** list, ensure to enter an appropriate temperature for **Non-Participating Boundary Zones Temperature**. In most cases the appropriate value is the ambient temperature, which by default is assumed to be 300 K.

After you have specified which zones do not participate in view factor calculation and set their temperature, click **OK** to store the settings and close the **Participating Boundary Zones** dialog box. You can then proceed to computing the view factors, as described in the section that follows.

12.3.4.2. Computing View Factors

ANSYS Fluent can compute the view factors for your problem in the current session and save them to a file for use in the current session and future sessions. Alternatively, you can save the surface cluster information and view factor parameters to a file, calculate the view factors outside ANSYS Fluent, and then read the view factors into ANSYS Fluent. These methods for computing view factors are described in the following sections.

Important

For large meshes or complex models, it is recommended that you calculate the view factors outside ANSYS Fluent and then read them into ANSYS Fluent before starting your simulation.

Note

You can accelerate view factor calculations by using ANSYS Fluent in parallel. For more information see Accelerating View Factor Calculations for General Purpose Computing on Graphics Processing Units (GPGPUs) (p. 2064).

12.3.4.2.1. Computing View Factors Inside ANSYS Fluent

To compute view factors in your current ANSYS Fluent session, you must first set the parameters for the view factor calculation in the **View Factors and Clustering** dialog box (see View Factors and Clustering Settings (p. 853) for details) and click **OK** to save them. When you have set the view factor and surface cluster parameters, click the **Compute/Write/Read...** button in the **View Factors and Clustering** group box of the **Radiation Model** dialog box. A **Select File** dialog box will open, prompting you for the name of the file in which ANSYS Fluent should save the surface cluster information and the view factors. Note that the option to **Write Binary Files** is enabled by default, in order to reduce the time needed to write and read the view factor files. When you click **OK** in the **Select File** dialog box, ANSYS Fluent will write the surface cluster information to the file. ANSYS Fluent will use the surface cluster information to compute the view factors, save the view factors to the same file, and then automatically

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

read the view factors. The ANSYS Fluent console will report the status of the view factor calculation. For example:

```
Completed 25% calculation of view factors

Completed 50% calculation of view factors

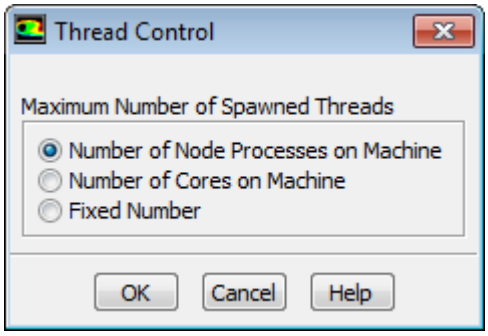
Completed 75% calculation of view factors

Completed 100 % calculation of view factors
```

Important

- You must recompute the view factors if you take any of following actions after the initial computation:
  - if you alter which boundary zones participate in the view factor calculation (either by using the **Participating Boundary Zones** dialog box, or by enabling / disabling the **Participates in View Factor Calculation** option in the **Radiation** tab of the boundary condition dialog box)
  - if you scale or unscale the mesh by using the **Scale Mesh** dialog box
- The view factor file format for this version of ANSYS Fluent is known as the compressed row format (CRF) and is a more efficient way of writing view factors than in versions that are prior to Fluent 6.4. In the CRF format, only nonzero view factors with their associated cluster IDs are stored to the file. This reduces the size of the `.s2s` file, and reduces the time it takes to read the file into ANSYS Fluent. While the CRF file format is the default, you can still use the older file format if necessary. Contact your support engineer for more information.
- View factors using ray tracing are computed with the MPI/OpenMP hybrid model for parallel runs. By default, one OpenMP thread is used per MPI process, as specified in the Thread Control Dialog Box (p. 2811) (see Controlling the Threads (p. 2058) for details). To use all the available cores on your machine as OpenMP threads, select **Number of Cores on Machine**. A **Fixed Number** of cores can also be used based on your needs.

Figure 12.18: The Thread Control Dialog Box



Note

For cases that use the S2S model and contain non-conformal interfaces, if the mesh interfaces are defined after the case has been read, then the intersection of the interface zones will occur during the initialization process, which will cause relabeling of faces

throughout the domain. If you attempt to compute view factors before solution initialization in such a case, then the following message will be displayed in the console and the view factors will be computed automatically during solution initialization to avoid a mismatch with the case file:

```
Intersection zones for non-conformal interfaces are not created.
View factors will be computed during solution initialization.
```

12.3.4.2.2. Computing View Factors Outside ANSYS Fluent

To compute view factors outside ANSYS Fluent, you must save the surface cluster information and view factor parameters to a file.

File → **Write** → **Surface Clusters...**

ANSYS Fluent will open the **View Factors and Clustering** dialog box, where you will set the view factor and surface cluster parameters (see View Factors and Clustering Settings (p. 853) for details). When you click **OK** in the **View Factors and Clustering** dialog box, a **Select File** dialog box will open, prompting you for the name of the file in which ANSYS Fluent should save the surface cluster information and view factor parameters to the file. If the specified **Filename** ends in `.gz` or `.Z`, appropriate file compression will be performed.

To calculate the view factors outside ANSYS Fluent, enter one of the following commands:

- For the serial solver:

  `utility viewfac` *inputfile*

  where *inputfile* is the filename, or the correct path to the filename, for the surface cluster information and view factor parameters file that you saved from ANSYS Fluent. You can then read the view factors into ANSYS Fluent, as described below.

- For the parallel solver:

  – Viewfac utility module:

  `utility viewfac -t` *nprocs* `[-p` *interconnect* `] [-mpi=` *mpi_type* `] [-cnf=` *hosts* `]` *inputfile*

  where *inputfile* is the filename, for which you will need to provide the full path.

  – Raytracing utility module:

  `utility raytracing -t` *nprocs* `[-p` *interconnect* `] [-mpi=` *mpi_type* `] [-cnf=` *hosts* `] [-ompthreads=` *N* `]` *inputfile*

  where *inputfile* is the filename, for which you will need to provide the full path.

  On Windows:
  `-t`*nprocs* specifies the number of processes to use. When the `-cnf` option is present, the hosts file argument is used to determine which machines to use for the parallel job. For example, if there are 8 machines listed in the hosts file and you want to run a job with 4 processes, set *nprocs* to 4 (that is `-t4`) and ANSYS Fluent will use the first 4 machines listed in the hosts file. Note that this does not apply to the Compute Cluster Server (CCS).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`-p`*interconnect* (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See Table 34.2: Supported Interconnects for the Windows Platform (p. 2023), Table 34.3: Available MPIs for Windows Platforms (p. 2023), and Table 34.4: Supported MPIs for Windows Architectures (Per Interconnect) (p. 2023) for more information.
`-mpi=`*mpi_type* (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect (IBM MPI) will be used (the use of the default MPI is recommended). The available MPIs for Windows are shown in Table 34.3: Available MPIs for Windows Platforms (p. 2023).
`-cnf=`*hosts* (optional) specifies the hosts file, which contains a list of the machines on which you want to run the parallel job. This option functions the same as that in the command for launching parallel Fluent; see Starting Parallel ANSYS Fluent on a Windows System Using Command Line Options (p. 2021) for details.
`-ompthreads=`*N* (optional) specifies that the desired number of OpenMP threads to be used per machine is *N*.

On Linux:
`-t`*nprocs* specifies the number of processes to used. When the `-cnf` option is present, the hosts file argument is used to determine which machines to use for the parallel job. For example, if there are 10 machines listed in the hosts file and you want to run a job with 5 processes, set *nprocs* to 5 (that is `-t5`) and ANSYS Fluent will use the first 5 machines listed in the hosts file.
`-p`*interconnect* (optional) specifies the type of interconnect. The ethernet interconnect is used by default if the option is not explicitly specified. See Table 34.5: Supported Interconnects for Linux Platforms (Per Platform) (p. 2028), Table 34.6: Available MPIs for Linux Platforms (p. 2028), and Table 34.7: Supported MPIs for Linux Architectures (Per Interconnect) (p. 2028) for more information.
`-mpi=`*mpi_type* (optional) specifies the type of MPI. If the option is not specified, the default MPI for the given interconnect will be used (the use of the default MPI is recommended). The available MPIs for Linux are shown in Table 34.6: Available MPIs for Linux Platforms (p. 2028).
`-cnf=`*hosts* (optional) specifies the hosts file, which contains a list of the machines on which you want to run the parallel job. This option functions the same as that in the command for launching parallel Fluent; see Starting Parallel ANSYS Fluent on a Linux System Using Command Line Options (p. 2026) for details.
`-ompthreads=`*N* (optional) specifies that the desired number of OpenMP threads to be used per machine is *N*.

12.3.4.3. Reading View Factors into ANSYS Fluent

If the view factors for your problem have already been computed (either inside or outside ANSYS Fluent) and saved to a file, you can read them into ANSYS Fluent. To read in the view factors, click **Read Existing File...** button in the **View Factors and Clustering** group box of the **Radiation Model** dialog box. A **Select File** dialog box will open where you can specify the name of the file containing the view factors. Alternatively, you can read the view factors file using the **File/Read/View Factors...** ribbon tab item.

Important

While the previous `.s2s` view factor file format can still be read seamlessly into ANSYS Fluent, there is now a more efficient compressed row format (CRF) that can be read into ANSYS Fluent (see the section on Computing View Factors Inside ANSYS Fluent). You can take advantage of the reduced size of the CRF file and therefore the reduced time it takes to read the file into ANSYS Fluent, by converting the existing old file format to the new format (without having to recompute the view factors) using the following command at the command prompt in your working directory:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
utility viewfac -c1 -o new.s2s.gz old.s2s.gz
```

where `new.s2s.gz` is the CRF format to which you want the old file format (`old.s2s.gz`) converted.

12.3.5. Setting Up the DO Model

For information about setting up the DO model, see the following sections:
12.3.5.1. Angular Discretization
12.3.5.2. Defining Non-Gray Radiation for the DO Model
12.3.5.3. Enabling DO/Energy Coupling

For information about accelerating the DO solver when running in parallel on Linux, see Accelerating Discrete Ordinates (DO) Radiation Calculations (p. 2065).

12.3.5.1. Angular Discretization

When you select the **Discrete Ordinates** model, the **Radiation Model** dialog box will expand to show inputs for **Angular Discretization** (see Figure 12.11: The Radiation Model Dialog Box (DO Model) (p. 846)). In this section, you will set parameters for the angular discretization and pixelation described in Angular Discretization and Pixelation in the Theory Guide.

Theta Divisions (N_θ) and **Phi Divisions** (N_ϕ) will define the number of control angles used to discretize each octant of the angular space (see Figure 5.3: Angular Coordinate System in the Theory Guide). Note that higher levels of discretization are recommended for problems where specular exchange of radiation is important to increase the likelihood of the correct beam direction being captured. For a 2D model, ANSYS Fluent will solve only 4 octants (due to symmetry); therefore, a total of $4N_\theta N_\phi$ directions $\vec{s}$ will be solved. For a 3D model, 8 octants are solved, resulting in $8N_\theta N_\phi$ directions $\vec{s}$. By default, the number of **Theta Divisions** and the number of **Phi Divisions** are both set to 2. For most practical problems, these settings are acceptable, however, a setting of 2 is considered to be a coarse estimate. Increasing the discretization of **Theta Divisions** and **Phi Divisions** to a minimum of 3, or up to 5, will achieve more reliable results. A finer angular discretization can be specified to better resolve the influence of small geometric features or strong spatial variations in temperature, but larger numbers of **Theta Divisions** and **Phi Divisions** will add to the cost of the computation.

Theta Pixels and **Phi Pixels** are used to control the pixelation that accounts for any control volume overhang (see Figure 5.7: Pixelation of Control Angle in the Theory Guide and the figures and discussion preceding it). For problems involving gray-diffuse radiation, the default pixelation of 1×1 is usually sufficient. For problems involving symmetry, periodic, specular, or semi-transparent boundaries, a pixelation of 3×3 is recommended and will achieve acceptable results. The computational effort, as a result of increasing the pixelation, is less than the computational effort caused by increasing the divisions. You should be aware, however, that increasing the pixelation adds to the cost of computation.

Important

Note that pixelations are applied to boundary faces by default.

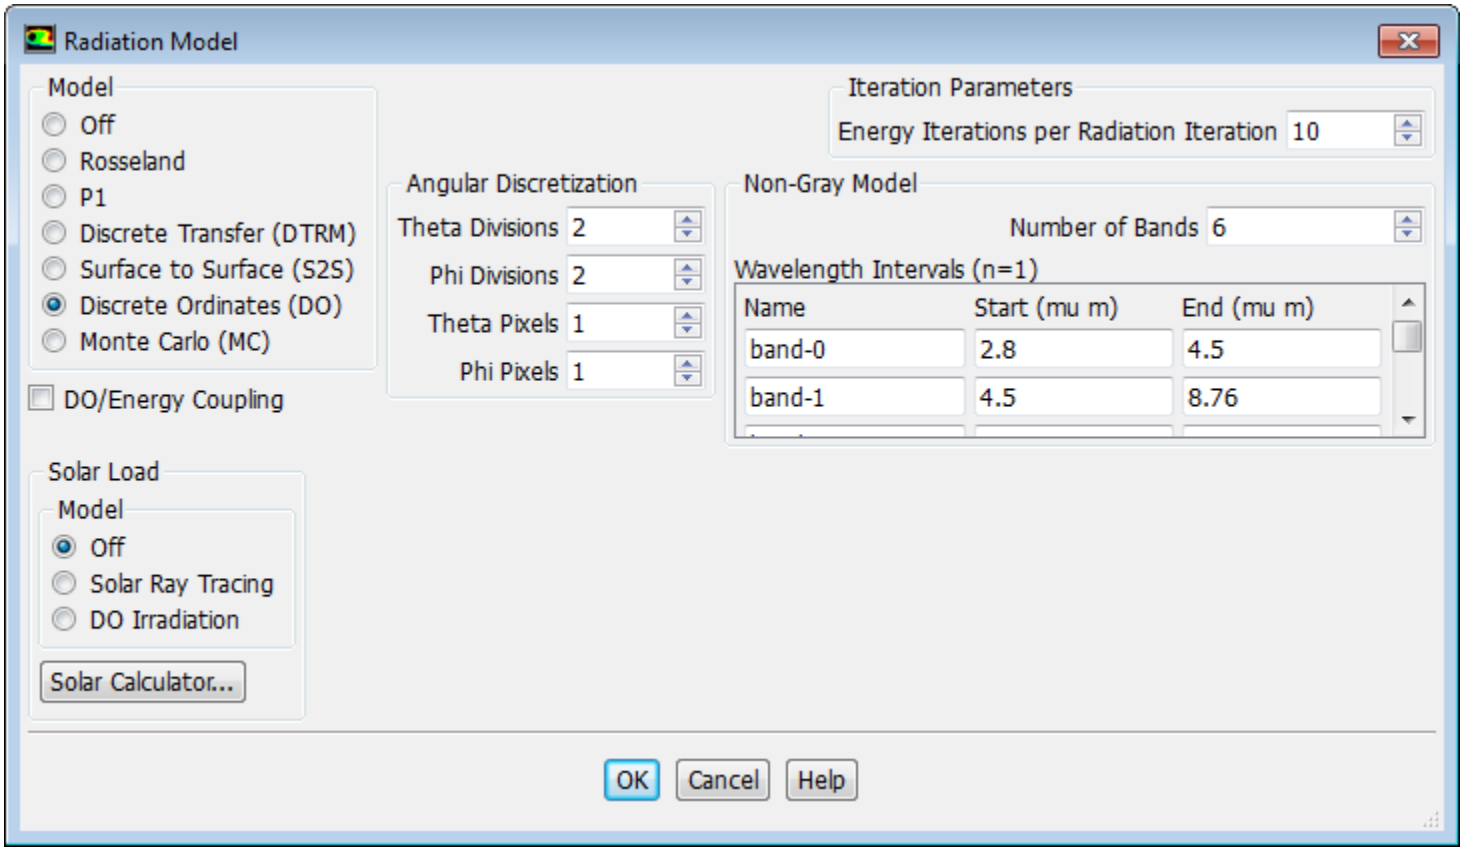
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.5.2. Defining Non-Gray Radiation for the DO Model

If you want to model non-gray radiation using the DO model, you can specify the **Number of Bands** (N) under **Non-Gray Model** in the expanded **Radiation Model** dialog box (Figure 12.19: The Radiation Model Dialog Box (Non-Gray DO Model) (p. 865)). For a 2D model, ANSYS Fluent will solve $4N_\theta N_\phi N$ directions. For a 3D model, $8N_\theta N_\phi N$ directions will be solved. By default, the **Number of Bands** is set to zero, indicating that only gray radiation will be modeled. Because the cost of computation increases directly with the number of bands, you should try to minimize the number of bands used. In many cases, the absorption coefficient or the wall emissivity is effectively constant for the wavelengths of importance in the temperature range of the problem. For such cases, the gray DO model can be used with little loss of accuracy. For other cases, non-gray behavior is important, but relatively few bands are necessary. For typical glasses, for example, two or three bands will frequently suffice.

When a nonzero **Number of Bands** is specified, the **Radiation Model** dialog box will expand once again to show the **Wavelength Intervals** (Figure 12.19: The Radiation Model Dialog Box (Non-Gray DO Model) (p. 865)). You can specify a **Name** for each wavelength band, as well as the **Start** and **End** wavelength of the band in μm. Note that the wavelength bands are specified for vacuum (n=1). ANSYS Fluent will automatically account for the refractive index in setting band limits for media with n different from unity.

Figure 12.19: The Radiation Model Dialog Box (Non-Gray DO Model)



The frequency of radiation remains constant as radiation travels across a semi-transparent interface. The wavelength, however, changes such that $n\lambda$ is constant. Therefore, when radiation passes from a medium with refractive index n_1 to one with refractive index n_2, the following relationship holds:

$$n_1\lambda_1 = n_2\lambda_2 \tag{12.8}$$

Here λ_1 and λ_2 are the wavelengths associated with the two media. It is conventional to specify the wavelength rather than frequency. ANSYS Fluent requires you to specify wavelength bands (in μm) for an equivalent medium with $n=1$.

For example, consider a typical glass with a step jump in the absorption coefficient at a cut-off wavelength of λ_c. The absorption coefficient is a_1 for $\lambda \leq \lambda_c$ and a_2 for $\lambda > \lambda_c$. The refractive index of the glass is n_g. Since $n\lambda$ is constant across a semi-transparent interface, the equivalent cut-off wavelength for a medium with $n=1$ is $n_g\lambda_c$ using Equation 12.8 (p. 865). You should choose two bands in this case, with the limits 0 to $n_g\lambda_c$ and $n_g\lambda_c$ to 100. Here, the upper wavelength limit has been chosen to be a large number, 100, in order to ensure that the entire spectrum is covered by the bands. When multiple materials exist, you should convert all the cut-off wavelengths to equivalent cut-off wavelengths for an $n=1$ medium, and choose the band boundaries accordingly.

The bands can have different widths and need not be contiguous. You can ensure that the entire spectrum is covered by your bands by choosing $\lambda_{min}=0$ and $n\lambda_{max}T_{min} \geq 50,000$. Here λ_{min} and λ_{max} are the minimum and maximum wavelength bounds of your wavelength bands, and T_{min} is the minimum expected temperature in the domain.

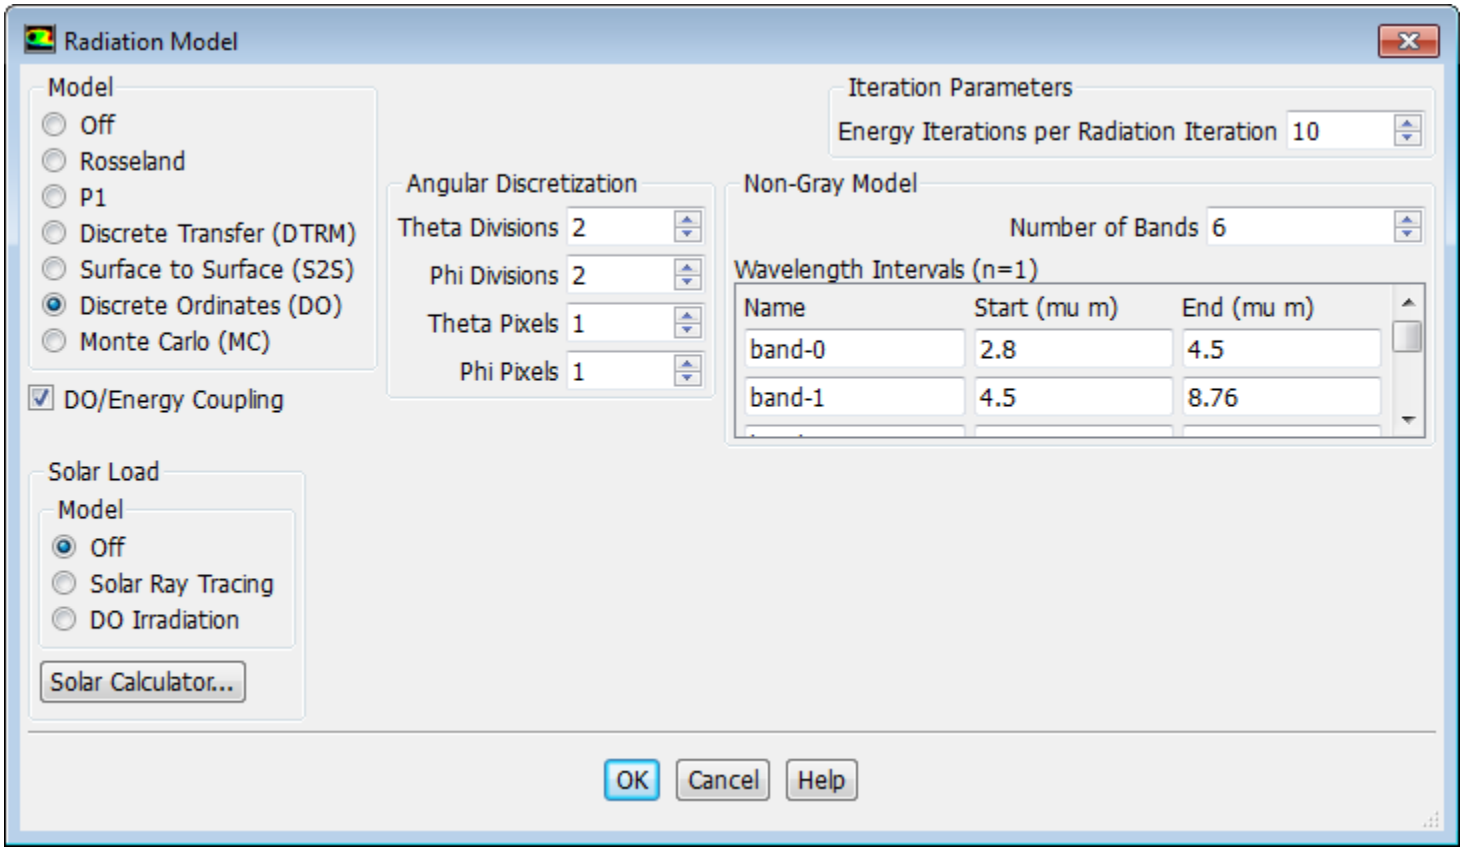
ANSYS Fluent allows you to use a user-defined function (UDF) to modify the emissivity weighting factor $F(0 \rightarrow n\lambda_2 T) - F(0 \rightarrow n\lambda_1 T)$ (which otherwise defaults to the black body emission factor obtained from a standard Planck distribution). The emissivity weighting factor appears in the emission term of the radiative transfer equation for the non-gray model, as shown in Equation 5.61 in the Theory Guide. For more information, see `DEFINE_EMISSIVITY_WEIGHTING_FACTOR` in the Fluent Customization Manual.

12.3.5.3. Enabling DO/Energy Coupling

For applications involving optical thicknesses greater than 10, you can enable the **DO/Energy Coupling** option in the **Radiation Model** (Figure 12.20: The Radiation Model Dialog Box with DO/Energy Coupling Enabled (p. 867)) in order to couple the energy and intensity equations at each cell, solving them simultaneously. This approach accelerates the convergence of the finite volume scheme for radiative heat transfer and can be used with the gray or non-gray radiation model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.20: The Radiation Model Dialog Box with DO/Energy Coupling Enabled



12.3.6. Setting Up the MC Model

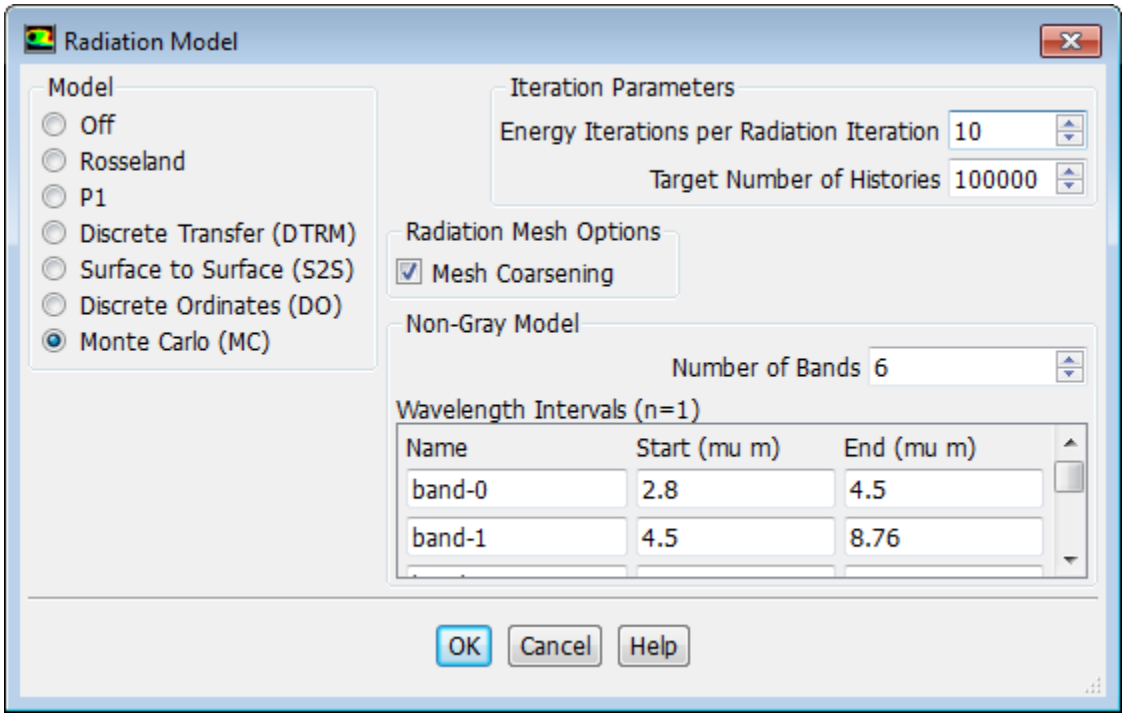
In the **Iteration Parameters** group box of the **Radiation Model** dialog box, you have the option of revising the **Target Number of Histories** to be tracked for the Monte Carlo (MC) simulation. The default value is 100,000. This can have a large effect on the accuracy of simulation results. For details, see Monte Carlo Solution Accuracy in the Theory Guide.

In the **Radiation Mesh Options** group box, you can enable **Mesh Coarsening**. **Mesh Coarsening** reduces the number of effective cells in the domain used by the MC radiation model. The coarsening is achieved by merging cells together and, therefore, does not affect the surface mesh resolution or alter the faces of any merged cells. The reduction in cells may speed up the radiation calculation and reduce peak memory usage, however, it may also have an impact on solution accuracy.

You have the option specifying multiple radiation bands using the **Non-Gray Model** group box. For each desired band, you must specify a start and end wavelength.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.21: The Radiation Model Dialog Box (MC)



12.3.7. Defining Material Properties for Radiation

When you are using the P-1, DO, MC, or Rosseland radiation model in ANSYS Fluent, you should be sure to define both the absorption and scattering coefficients of the fluid in the **Create/Edit Materials** dialog box. Note that you can either enter a constant value for these parameters, or you can specify them using a user-defined function (UDF). For more information, see DEFINE_PROPERTY UDFs in the Fluent Customization Manual.

Setup → Materials

If you are modeling semi-transparent media using the DO or MC model, you should also define the refractive index for the semi-transparent fluid or solid material. When using the Rosseland model, you can specify the refractive index only for the fluid material. When using the P-1 model, you should define the refractive index for the fluid material only. For the DTRM, you need to define only the absorption coefficient.

If your model includes gas phase species such as combustion products, absorption and/or scattering in the gas may be significant. The scattering coefficient should be increased from the default of zero if the fluid contains dispersed particles or droplets that contribute to scattering. Alternatively, you can specify the scattering coefficient as a user-defined function (UDF). For more information, see DEFINE_PROPERTY UDFs in the Fluent Customization Manual.

Note

You cannot use a UDF to define any material properties when using the MC model.

ANSYS Fluent allows you to enter a composition-dependent absorption coefficient for CO_2 and H_2O mixtures, using the WSGGM. The method for computing a variable absorption coefficient is described

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in Radiation in Combusting Flows in the Theory Guide. Radiation Properties (p. 515) provides a detailed description of the procedures used for specification of radiation properties.

12.3.7.1. Absorption Coefficient for a Non-Gray Model

If you are using the non-gray P-1, DO, or MC model, you can specify a different constant absorption coefficient for each of the bands used by the gray-band model, as described in Radiation Properties (p. 515). You cannot, however, compute a composition-dependent absorption coefficient in each band. If you use the WSGGM to compute a variable absorption coefficient, the value will be the same for all bands. Alternatively, you can specify a user-defined function (UDF) for the absorption coefficient. For more information, see DEFINE_PROPERTY UDFs in the Fluent Customization Manual.

12.3.7.2. Refractive Index for a Non-Gray Model

If you are using the non-gray P-1, DO, or MC model, you can specify a different constant refractive index for each of the bands used by the gray-band model, as described in Radiation Properties (p. 515). You cannot, however, compute a composition-dependent refractive index in each band.

12.3.8. Defining Boundary Conditions for Radiation

When you set up a problem that includes radiation, you will set additional boundary conditions at inlets, exits, and walls. These inputs are described in the sections that follow. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

Setup → **Boundary Conditions**

12.3.8.1. Inlet and Exit Boundary Conditions

12.3.8.1.1. Emissivity

When radiation is active, you can define the emissivity at each inlet and exit boundary when you are defining boundary conditions in the associated inlet or exit boundary dialog box (for example, **Pressure Inlet** dialog box, **Velocity Inlet** dialog box, **Pressure Outlet** dialog box). Enter the appropriate value for **Internal Emissivity**. The default value for all boundary types is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see DEFINE_PROFILE in the Fluent Customization Manual.

For the non-gray P-1 model and the non-gray DO model, the specified constant emissivity will be used for all wavelength bands.

Important

The **Internal Emissivity** boundary condition is not available with the Rosseland model.

12.3.8.1.2. Black Body Temperature

ANSYS Fluent includes an option that allows you to take into account the influence of the temperature of the gas and the walls beyond the inlet/exit boundaries, and specify different temperatures for radiation and convection at inlets and exits. This is useful when the temperature outside the inlet or exit differs considerably from the temperature in the enclosure. For example, if the temperature of the walls beyond

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the inlet is 2000 K and the temperature at the inlet is 1000 K, you can specify the outside wall temperature to be used for computing radiative heat flux, while the actual temperature at the inlet is used for calculating convective heat transfer. To do this, you would specify a radiation temperature of 2000 K as the black body temperature.

Although this option allows you to account for both cooler and hotter outside walls, you must use caution in the case of cooler walls, since the radiation from the immediate vicinity of the hotter inlet or outlet almost always dominates over the radiation from cooler outside walls. If, for example, the temperature of the outside walls is 250 K and the inlet temperature is 1500 K, it might be misleading to use 250 K for the radiation boundary temperature. This temperature might be expected to be somewhere between 250 K and 1500 K; in most cases it will be close to 1500 K. Its value depends on the geometry of the outside walls and the optical thickness of the gas in the vicinity of the inlet.

In the flow inlet or exit dialog box (for example, **Pressure Inlet** dialog box, **Velocity Inlet** dialog box), select **Specified External Temperature** in the **External Black Body Temperature Method** drop-down list, and then enter the value of the radiation boundary temperature as the **Black Body Temperature**.

Important

- If you want to use the same temperature for radiation and convection, retain the default selection of **Boundary Temperature** as the **External Black Body Temperature Method**.
- The **Black Body Temperature** boundary condition is not available with the Rosseland model.

12.3.8.2. Wall Boundary Conditions for the DTRM, and the P-1, S2S, and Rosseland Models

The DTRM and the S2S, Rosseland, and gray P-1 (that is, **Number of Bands** is set to zero) models assume all walls to be gray and diffuse. The only radiation boundary condition required in the **Wall** dialog box is the emissivity. For the Rosseland model, the internal emissivity is 1. For the DTRM and the S2S and gray P-1 models, you can enter the appropriate value for **Internal Emissivity** in the **Thermal** tab of the **Wall** dialog box. The default value is 1. Alternatively, you can specify a user-defined function for emissivity. For more information, see `DEFINE_PROFILE` in the Fluent Customization Manual.

For the non-gray P–1 model, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box (the default value in each band is 1). Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 246)). See Defining Boundary Conditions for Radiation (p. 869) for details.

12.3.8.2.1. Boundary Conditions for the S2S Model

When the S2S model is used, you can specify that some of the walls and inlet and exit boundaries are not participating in the view factor calculation. This capability allows you to save time computing the view factors and also reduce the memory required to store the view factor file during the ANSYS Fluent calculation. See Specifying Boundary Zone Participation (p. 858) for details.

Important

- Whenever you revise which boundary zones participate in the calculation, you will need to re-compute the view factors.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Flux Reports** dialog box will not show the exact balance of the **Radiation Heat Transfer Rate** because the radiative heat transfer to those boundaries that do not participate in the view factor calculation is not included.

12.3.8.3. Wall Boundary Conditions for the DO Model

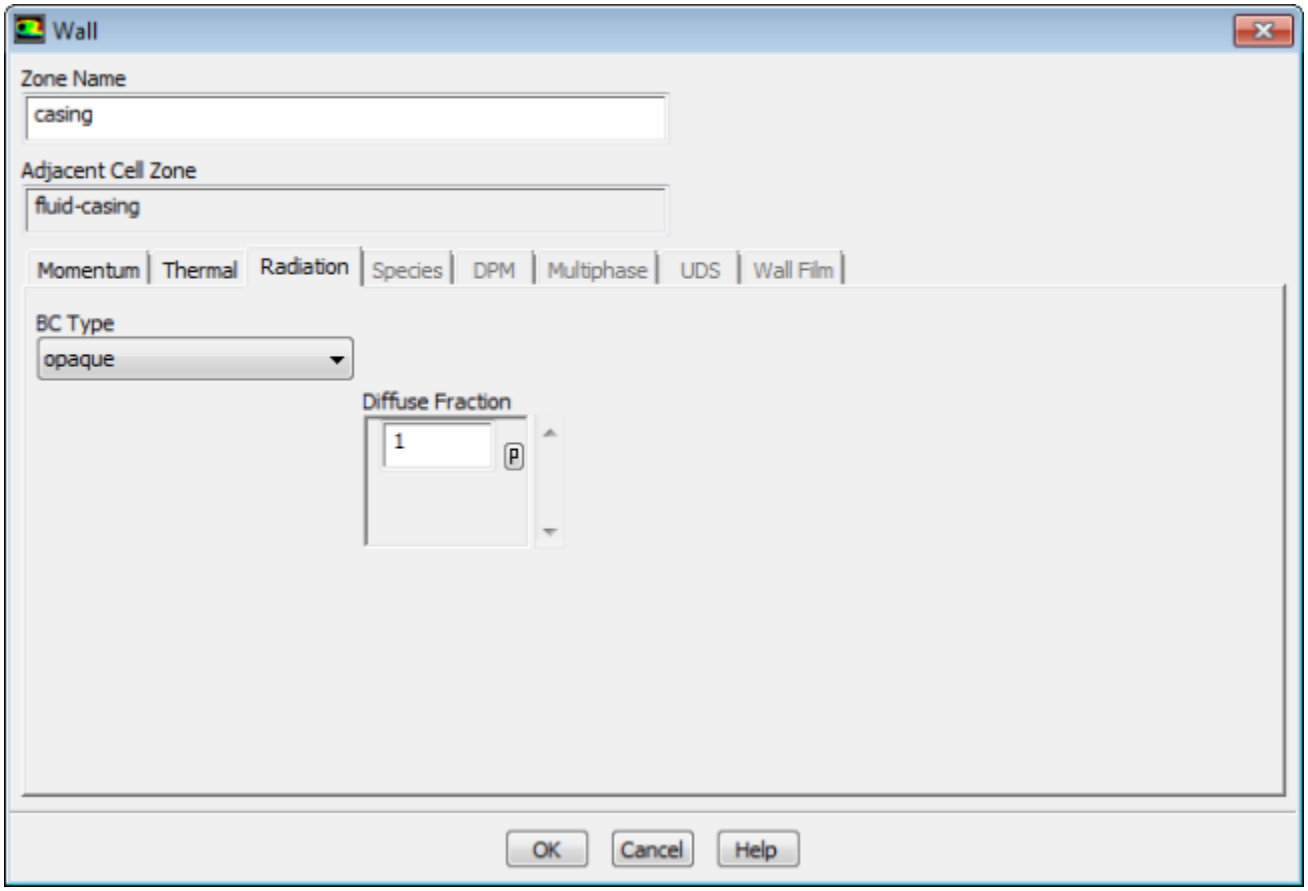
When the DO model is used, you can model opaque walls, as discussed in Boundary and Cell Zone Condition Treatment at Opaque Walls in the Theory Guide, as well as semi-transparent walls (Cell Zone and Boundary Condition Treatment at Semi-Transparent Walls in the Theory Guide).

You can use a diffuse wall to model wall boundaries in many industrial applications since, for the most part, surface roughness makes the reflection of incident radiation diffuse. For highly polished surfaces, such as reflectors or mirrors, the specular boundary condition is appropriate. The semi-transparent boundary condition can be appropriate, for example, when modeling for glass panes in air.

12.3.8.3.1. Opaque Walls

In the **Radiation** tab of the **Wall** dialog box (Figure 12.22: The Wall Dialog Box Showing Radiation Conditions for an Opaque Wall (p. 871)), select **opaque** in the **BC Type** drop-down list to specify an opaque wall. Opaque walls are treated as gray if gray radiation is being computed, or non-gray if the non-gray DO model is being used. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band.

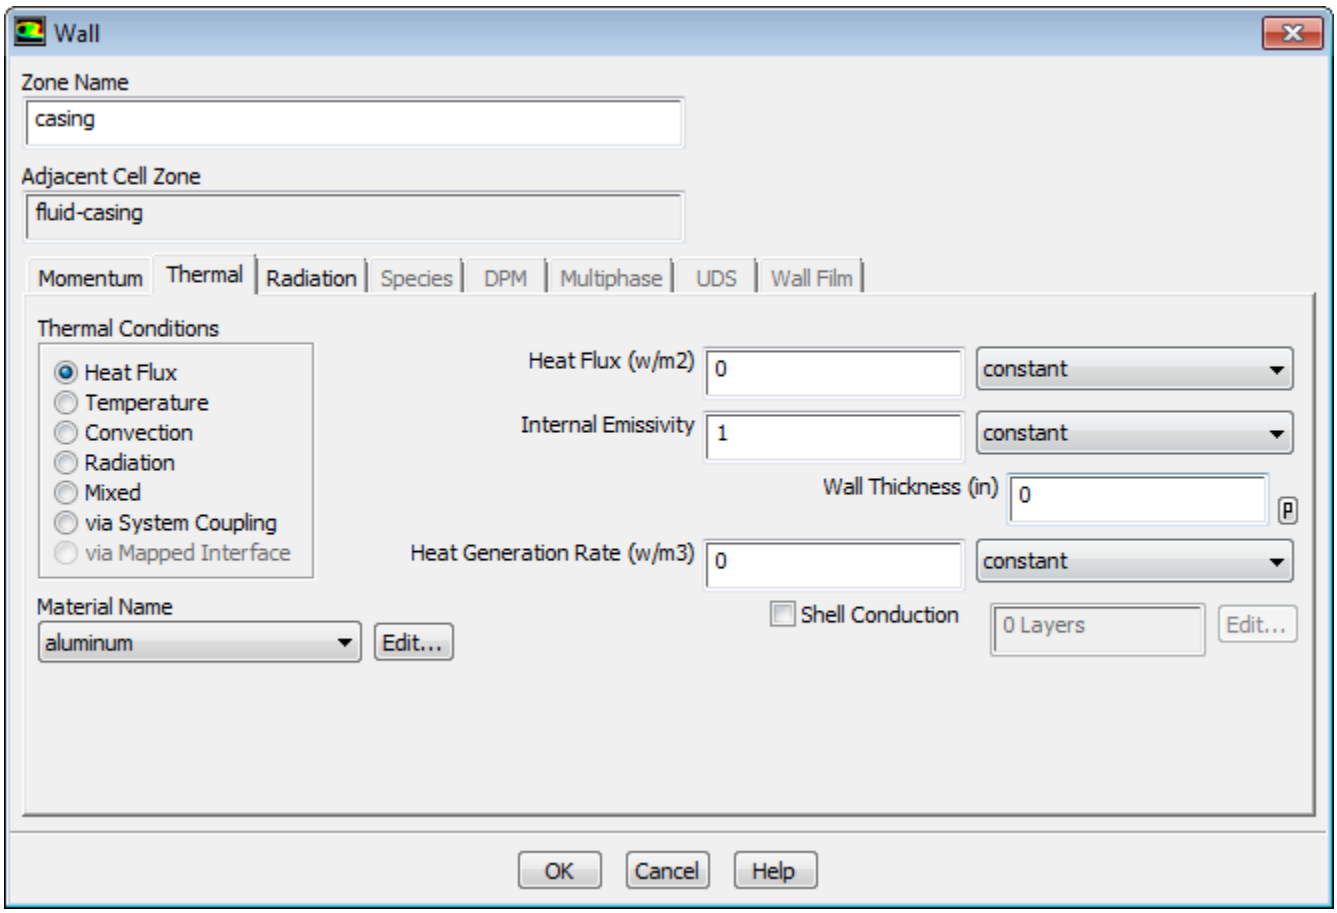
Figure 12.22: The Wall Dialog Box Showing Radiation Conditions for an Opaque Wall



After you have selected **opaque** as the **BC Type**, you can specify the fraction of reflected radiation flux that is to be treated as diffuse. By default, the **Diffuse Fraction** is set to 1, indicating that all of the radiation is diffuse. A diffuse fraction equal to 0 indicates purely specular reflected radiation. A diffuse fraction between 0 and 1 will result in partially diffuse and partially specular reflected energy. See Boundary and Cell Zone Condition Treatment at Opaque Walls in the Theory Guide for more details.

You will also be required to specify the internal emissivity in the **Thermal** tab of the **Wall** dialog box (Figure 12.23: The Wall Dialog Box Showing Internal Emissivity Thermal Conditions for an Opaque Wall (p. 872)). For gray-radiation DO models, enter the appropriate value for **Internal Emissivity**. (The default value is 1.) The value that you specify will be applied to the diffuse component only. For non-gray DO models, specify a constant **Internal Emissivity** for each wavelength band in the **Radiation** tab of the **Wall** dialog box. (The default value in each band is 1.) Alternatively, you can specify the internal emissivity using a boundary condition parameter (see Creating a New Parameter (p. 246)).

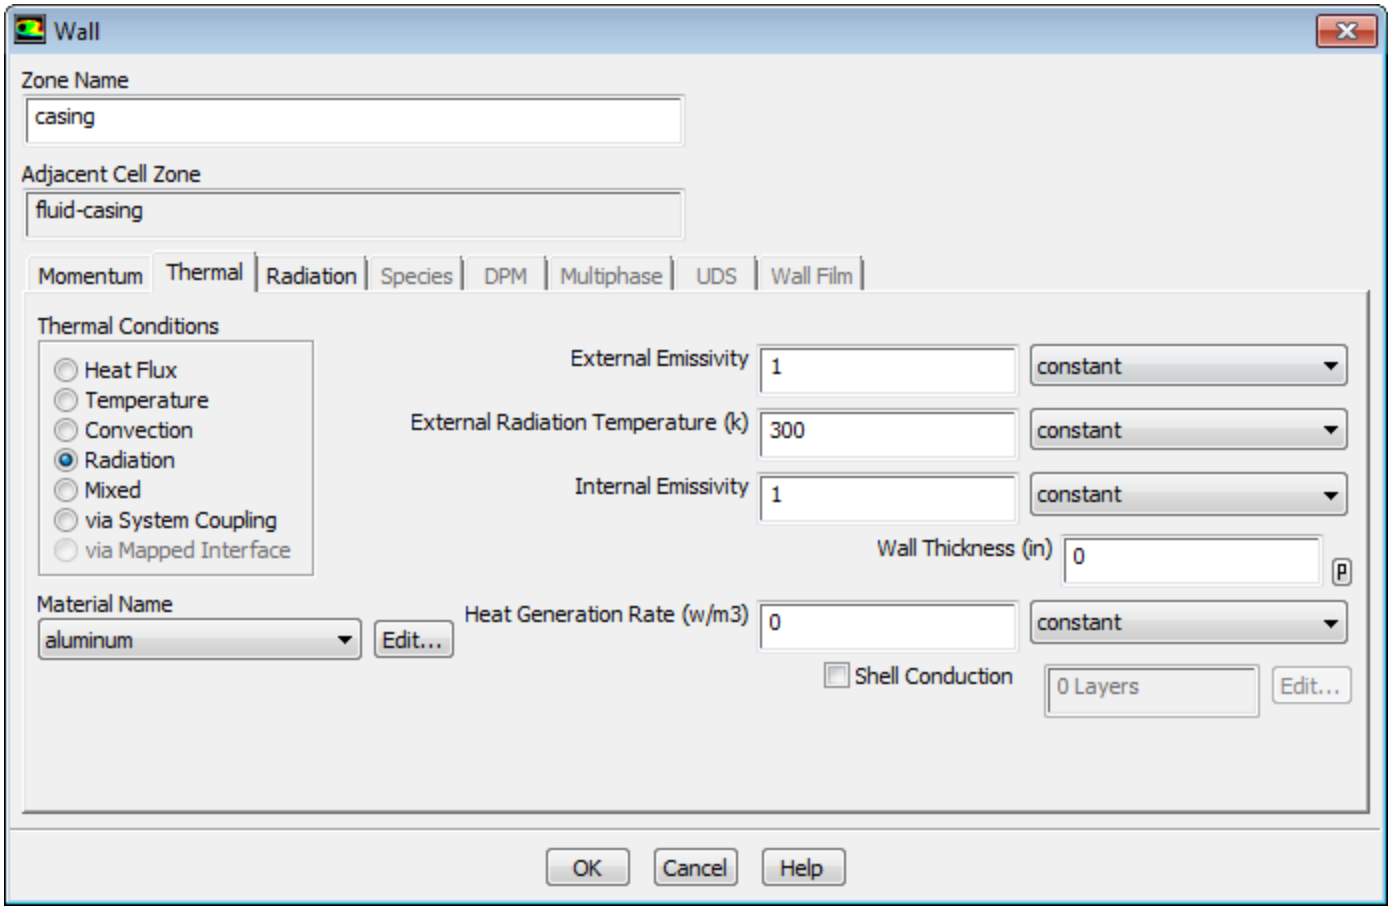
Figure 12.23: The Wall Dialog Box Showing Internal Emissivity Thermal Conditions for an Opaque Wall



You can also specify the external emissivity and external radiation temperature for an opaque wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box (Figure 12.24: The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions (p. 873)). Alternatively, you can specify a UDF for these parameters; for more information, see `DEFINE_PROFILE` in the Fluent Customization Manual.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.24: The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions



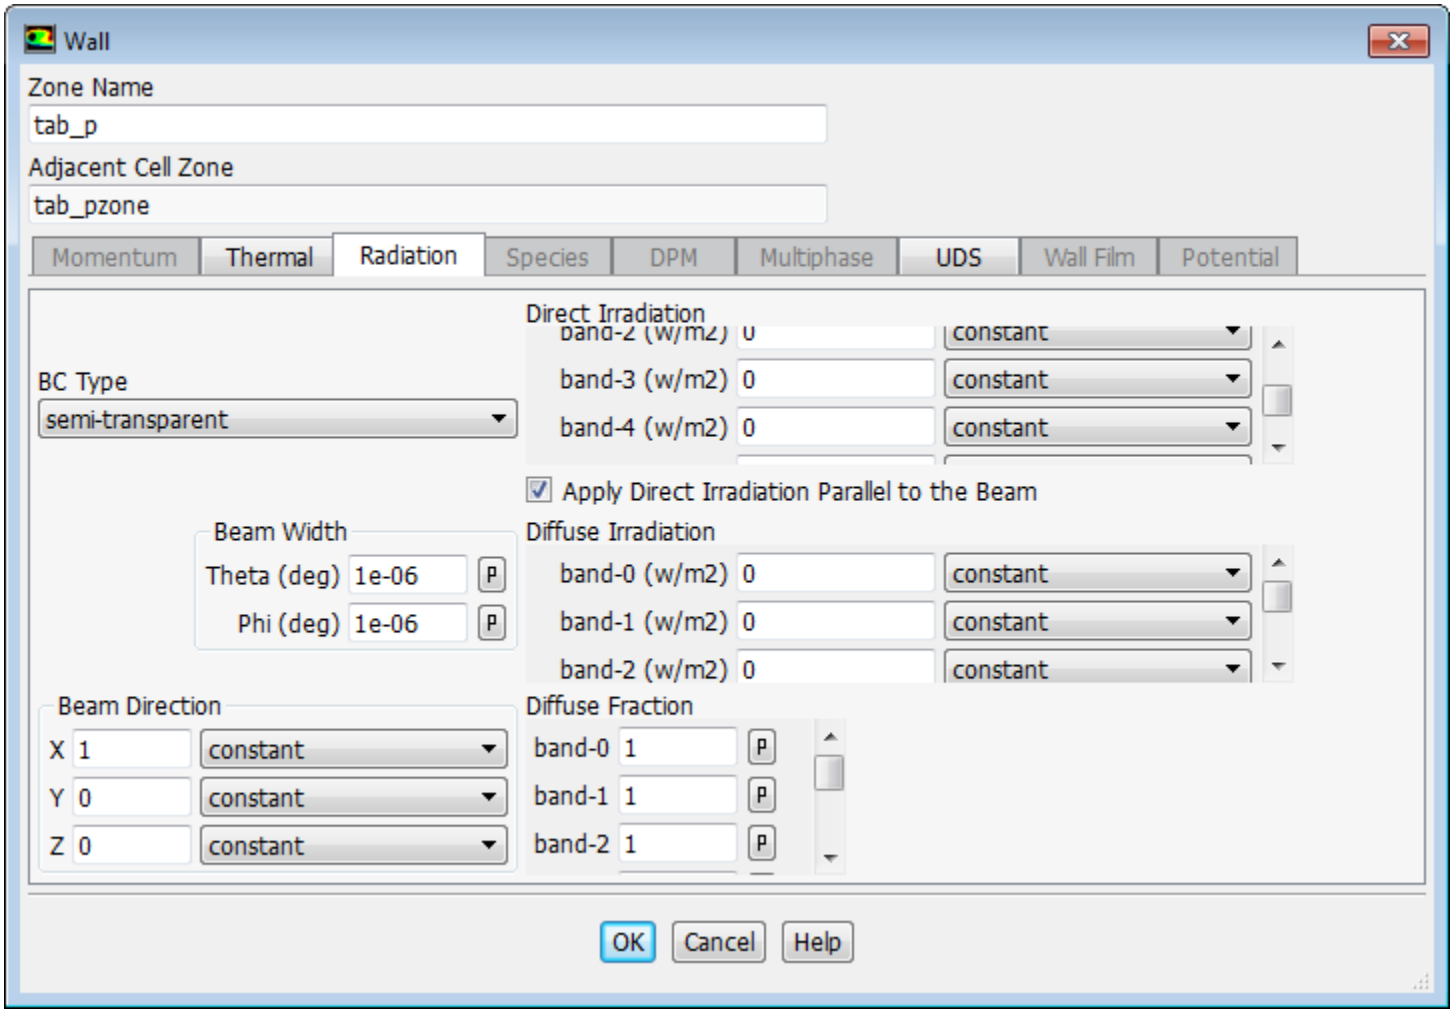
For more information on boundary condition treatment at opaque walls, see Boundary and Cell Zone Condition Treatment at Opaque Walls in the Theory Guide.

12.3.8.3.2. Semi-Transparent Walls

To define radiation for an exterior semi-transparent wall, click the **Radiation** tab in the **Wall** dialog box and then select **semi-transparent** in the **BC Type** drop-down list (Figure 12.25: The Wall Dialog Box for a Semi-Transparent Wall Boundary (p. 874)). The dialog box will expand to display the semi-transparent wall inputs needed to define an external irradiation flux (Figure 12.25: The Wall Dialog Box for a Semi-Transparent Wall Boundary (p. 874)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.25: The Wall Dialog Box for a Semi-Transparent Wall Boundary



Then perform the following steps:

1. Specify the value of the irradiation flux (in W/m^2) under **Direct** or **Diffuse Irradiation**. If the non-gray DO model is being used, a constant **Direct** or **Diffuse Irradiation** can be specified for each band.

   Important

   Note that the external diffuse irradiation specified when using **Radiation** or **Mixed** thermal conditions (selected in the **Thermal** tab), or **Diffuse Irradiation** (in the **Radiation** tab) is always distributed hemispherically after transmission through semi-transparent walls (that is independent of whether the external semi-transparent boundary wall is defined as a diffusely or specularly reflecting type).

2. **Apply Direct Irradiation Parallel to the Beam** is the default means of specifying the scale of irradiation flux. When enabled, ANSYS Fluent assumes that the value of **Direct Irradiation** that you specify is the irradiation flux parallel to the **Beam Direction**. When deselected, ANSYS Fluent instead assumes that the value specified is the flux parallel to the face normals and will calculate the resulting beam parallel flux for every face. See Figure 5.12: DO Irradiation on External Semi-Transparent Wall in Semi-Transparent Exterior Walls in the Theory Guide for details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Define the **Beam Width** by specifying the beam **Theta** and **Phi** extents. Beam width is specified as the solid angle over which the irradiation is distributed. The default value for beam width is $1e^{-6}$, which is suitable for collimated beam radiation. A beam width less than this is likely to result in zero irradiation flux.

4. Specify the (**X,Y,Z**) vector that defines the **Beam Direction**. The beam direction is defined as the vector of the centroid of the solid angle (beam width). You can specify the **Beam Direction** as a constant, a profile or a UDF. This is especially useful in applications where the shape of the radiative source is circular or cylindrical (or nonlinear). For information about boundary profiles, see Reading and Writing Profile Files (p. 53).

   Note that the actual direction of the beam of radiation that enters the domain will be further influenced by the solid angles available from the number of divisions set up; the effective direction will be the direction vector of the solid angle that the incoming beam falls into. Finally, any nonzero diffuse fraction will act to spread out (hemispherically, proportional to the diffuse fraction) the irradiation that enters the domain.

   For a UDF example that specifies the beam direction, see Example 5 - Beam Direction Profile at Semi-Transparent Walls in the Fluent Customization Manual.

5. Specify the fraction of the irradiation that is to be treated as diffuse as a real number between 0 and 1. By default, the **Diffuse Fraction** is set to 1, indicating that all of the irradiation is diffuse. A diffuse fraction of 0 treats the radiation as purely specular. If you specify a value between 0 and 1, the radiation is treated as partially diffuse and partially specular. If the non-gray DO model is being used, the **Diffuse Fraction** can be specified for each band. See Diffuse Semi-Transparent Walls in the Theory Guide for details.

Important

- Note that the refractive index of the external medium is assumed to be 1.
- If **Heat Flux** conditions are specified in the **Thermal** tab of the **Wall** dialog box, the specified heat flux is considered to be only the conduction and convection portion of the boundary flux. The given irradiation specifies the incoming exterior radiative flux; the radiative flux transmitted from the domain interior to the outside is computed as a part of the calculation by ANSYS Fluent. Internal emissivity is ignored for semi-transparent surfaces.
- Note that when a boundary wall is made semi-transparent ANSYS Fluent calculates the amount of radiation leaving as well as entering the domain. If you do not provide a source of irradiation or a radiating thermal condition (for example **Mixed** or **Radiation**) then you are effectively radiating to a temperature of 0 K and it is highly likely you may observe temperatures in your model that are lower than expected. Ensure that the external (incoming) radiant conditions give good account of the surroundings.

You can also specify the external emissivity and external radiation temperature for a semi-transparent wall when the thermal conditions are set to **Radiation** or **Mixed** in the **Wall** dialog box (Figure 12.24: The Wall Dialog Box Showing External Emissivity and External Radiation Temperature Thermal Conditions (p. 873)). Alternatively, you can specify a user-defined function (UDF) for these parameters; for more information, see `DEFINE_PROFILE` in the Fluent Customization Manual.

For a detailed description of boundary condition treatment at semi-transparent walls, see Cell Zone and Boundary Condition Treatment at Semi-Transparent Walls in the Theory Guide.

To define radiation for an interior (two-sided) semi-transparent wall, in the **Wall** dialog box click the **Radiation** tab and then select **semi-transparent** in the **BC Type** drop-down list (Figure 12.26: The Wall

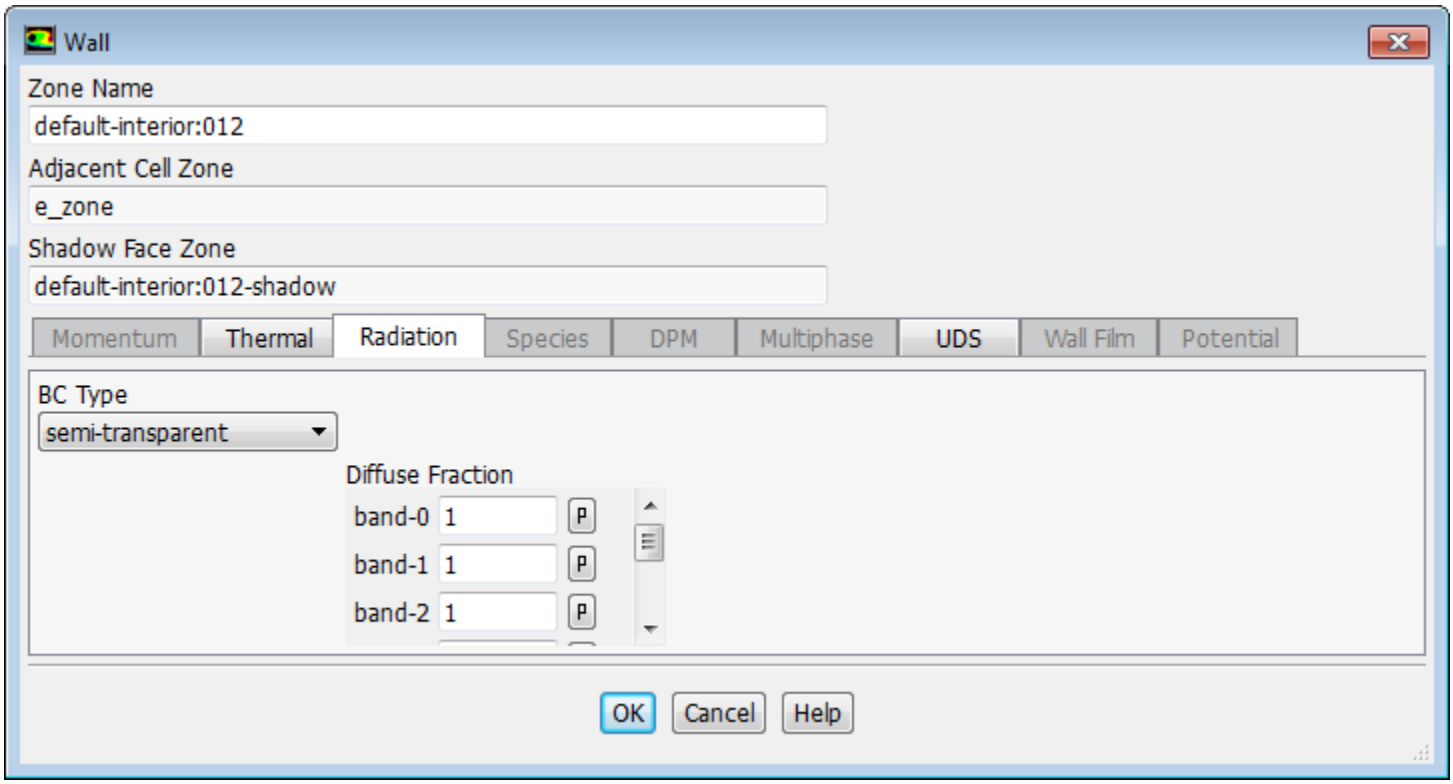
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Dialog Box for an Interior Semi-Transparent Wall (p. 876)). Then specify the **Diffuse Fraction** as described for the previous case.

Important

Note that for semi-transparent walls, the internal emissivity defined under thermal conditions is ignored. If you want to include the effect of internal emissivity at semi-transparent walls, you must create a solid zone and specify that it participates in the radiation calculation; see Solid Semi-Transparent Media in the Theory Guide for details.

Figure 12.26: The Wall Dialog Box for an Interior Semi-Transparent Wall



12.3.8.4. Boundary Conditions for the MC Model

When the MC model is used, you can define the boundaries in a similar manner as for the DO model, with the following differences:

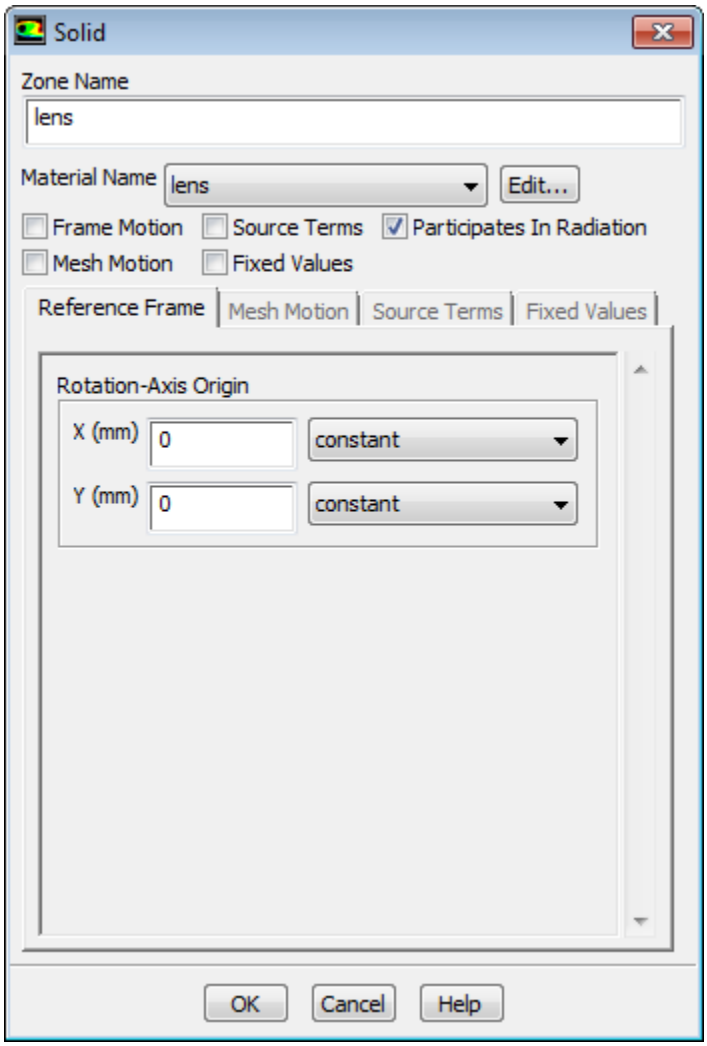
- The MC model does not require a beam width.
- For opaque walls, the MC model allows you to enable a **Boundary Source** option, which allows you to specify the **Beam Direction** and the **Direct Irradiation**.
- To model diffuse irradiation, you must set the **Beam Direction** to 0.
- The semi-transparent boundary condition is not supported on external walls
- Unlike the DO model, direct irradiation cannot be defined for semi-transparent walls.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.8.5. Solid Cell Zones Conditions for the DO Model

With the DO model, you can specify whether or not you want to solve for radiation in each cell zone in the domain. By default, the DO equations are solved in all fluid zones, but not in any solid zones. If you want to model semi-transparent media, for example, you can enable radiation in the solid zone(s). To do so, enable the **Participates In Radiation** option in the **Solid** dialog box (Figure 12.27: The Solid Dialog Box (p. 877)).

Figure 12.27: The Solid Dialog Box



Important

In general, you should *not* disable the **Participates In Radiation** option for any fluid zones.

See Solid Semi-Transparent Media in the Theory Guide for more information on solid semi-transparent media.

12.3.8.6. Thermal Boundary Conditions

In general, any well-posed combination of thermal boundary conditions can be used when any of the radiation models is active. The radiation model will be well-posed in combination with fixed temperature walls, conducting walls, and/or walls with set external heat transfer boundary conditions (Thermal

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Boundary Conditions at Walls (p. 370)). You can also use any of the radiation models with heat flux boundary conditions defined at walls, in which case the heat flux you define will be treated as the sum of the convective and radiative heat fluxes. The exception to this is the case of semi-transparent walls for the DO model. Here, ANSYS Fluent allows you to specify the convective and radiative portions of the heat flux separately.

12.3.9. Solution Strategies for Radiation Modeling

For the P-1, DTRM, S2S, and the DO radiation models, there are several parameters that control the radiation calculation. You can use the default solution parameters for most problems, or you can modify these parameters to control the convergence and accuracy of the solution. Iteration parameters that are unique for a particular radiation model are specified in the **Radiation Model** dialog box (for example, **Energy Iterations per Radiation Iteration**). **Spatial Discretization** (Discretization in the Theory Guide) and **Under-Relaxation Factors** (Under-Relaxation of Variables in the Theory Guide) are specified in the **Solution Methods** and **Solution Controls** task pages, respectively. The **Convergence Criterion** (Modifying Convergence Criteria (p. 1631)) is set in the **Residual Monitors** dialog box.

There are no solution parameters to be set for the Rosseland model, since it impacts the solution only through the energy equation.

Important

If radiation is the only model being solved in ANSYS Fluent and all other equations are disabled, then the radiation transfer equation will automatically be solved for every iteration, regardless of what the **Energy Iterations per Radiation Iteration** field is set to in the user interface.

12.3.9.1. P-1 Model Solution Parameters

For the P-1 radiation model, you can control the convergence criterion and under-relaxation factor. You should also pay attention to the optical thickness, as described below.

The default convergence criterion for the P-1 model is 10^{-6}, the same as that for the energy equation, since the two are closely linked. See Monitoring Residuals (p. 1624) for details about convergence criteria. You can set the **Convergence Criterion** for **p1** in the **Residual Monitors** dialog box.

Solution → **Monitors** → **Residuals** **Edit...**

The under-relaxation factor for the P-1 model is set with those for other variables, as described in Setting Under-Relaxation Factors (p. 1564). Note that since the equation for the radiation temperature (Equation 5.21 in the Theory Guide) is a relatively stable scalar transport equation, in most cases you can safely use large values of under-relaxation (0.9–1.0).

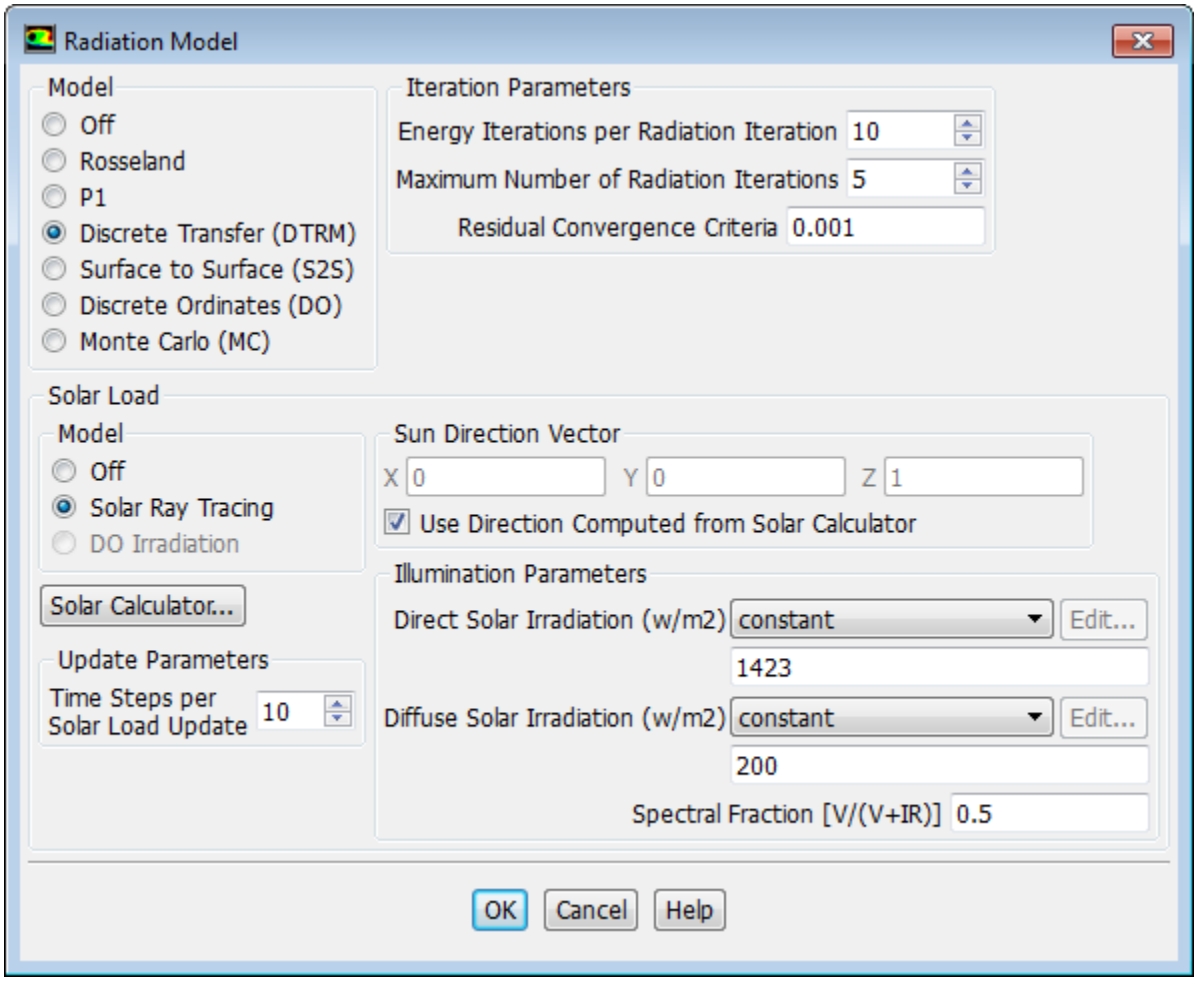
For optimal convergence with the P-1 model, the optical thickness $(a+\sigma_s)L$ must be between 0.01 and 10 (preferably not larger than 5). Smaller optical thicknesses are typical for very small enclosures (characteristic size of the order of 1 cm), but for such problems you can safely increase the absorption coefficient to a value for which $(a+\sigma_s)L=0.01$. Increasing the absorption coefficient will not change the physics of the problem because the difference in the level of transparency of a medium with optical thickness = 0.01 and one with optical thickness <0.01 is indistinguishable within the accuracy level of the computation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.9.2. DTRM Solution Parameters

When the DTRM is active, ANSYS Fluent updates the radiation field during the calculation and computes the resulting energy sources and heat fluxes via the ray-tracing technique described in Ray Tracing in the Theory Guide. ANSYS Fluent provides several solution parameters in the expanded portion of the **Radiation Model** dialog box (Figure 12.28: The Radiation Model Dialog Box (DTRM) (p. 879)).

Figure 12.28: The Radiation Model Dialog Box (DTRM)



You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the **Maximum Number of Radiation Iterations**. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The **Residual Convergence Criteria** parameter (0.001 by default) determines when the radiation intensity update is converged. It is defined as the maximum normalized change in the surface intensity from one DTRM radiation iteration to the next (see Equation 12.9 (p. 881)).

You can also control the frequency that the radiation field is updated as the continuous phase solution proceeds. The **Energy Iterations per Radiation Iteration** parameter is set to 10 by default. This means that the radiation calculation is performed once every 10 iterations of the solution process. Increasing the number can speed the calculation process, but may slow overall convergence.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.9.3. S2S Solution Parameters

For the S2S model, as for the DTRM, you can control the frequency with which the radiosity is updated as the continuous-phase solution proceeds. See the previous description of **Energy Iterations per Radiation Iteration**.

If you are using the pressure-based solver and you first solve the flow equations with the energy equation turned off, you should reduce the **Energy Iterations per Radiation Iteration** from 10 to 1 or 2. This will ensure the convergence of the radiosity. If the default value of 10 is kept in this case, it is possible that the flow and energy residuals may converge and the solution will terminate before the radiosity is converged. See Residual Reporting for the S2S Model (p. 881) for more information about residuals for the S2S model.

You can control the maximum number of iterations of the radiation calculation during each global iteration by changing the **Maximum Number of Radiation Iterations**. The default setting of 5 means that the radiosity will be updated up to 5 times. The actual number of iterations will be less if the residual convergence criterion is exceeded at any point during these iterations.

The **Residual Convergence Criteria** (0.001 by default) determines when the radiosity update is converged. It is defined as the maximum normalized change in the radiosity from one S2S radiation iteration to the next (see Equation 12.10 (p. 881)).

12.3.9.4. DO Solution Parameters

For the discrete ordinates model, as for the DTRM, you can control the frequency that the surface intensity is updated as the continuous phase solution proceeds through the **Energy Iterations per Radiation Iteration** setting. See the description of DTRM Solution Parameters (p. 879).

For most problems, the default under-relaxation of 1.0 for the DO equations is adequate. For problems with large optical thicknesses ($aL>10$), you may experience slow convergence or solution oscillation. For such cases, under-relaxing the energy and DO equations is useful. Under-relaxation factors between 0.9 and 1.0 are recommended for both equations.

12.3.9.5. MC Solution Parameters

For the MC model, as for the DTRM, you can control the frequency that the surface intensity is updated as the continuous phase solution proceeds through the **Energy Iterations per Radiation Iteration** setting. See the description of DTRM Solution Parameters (p. 879).

12.3.9.6. Running the Calculation

Once the radiation problem has been set up, you can proceed as usual with the calculation. Note that while the P-1 and DO models will solve additional transport equations and report residuals, the DTRM and the Rosseland and S2S models will not (since they impact the solution only through the energy equation). Residuals for the DTRM and S2S model radiation iterations are reported by ANSYS Fluent every time such an iteration is performed, as described below.

When running the S2S model with the parallel solver, note that coupled walls are encapsulated, which may cause problems with the partitioning of the mesh. See Troubleshooting (p. 2056) for recommendations on correcting such problems.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.9.6.1. Residual Reporting for the P-1 Model

The residual for radiation as calculated by the P-1 model is updated after each iteration and reported with the residuals for all other variables. ANSYS Fluent reports the normalized P-1 radiation residual as defined in Monitoring Residuals (p. 1624) for the other transport equations.

12.3.9.6.2. Residual Reporting for the DO Model

After each DO iteration, the DO model reports a composite normalized residual for all the DO transport equations. The definition of the residuals is similar to that for the other transport equations (see Monitoring Residuals (p. 1624)).

12.3.9.6.3. Residual Reporting for the DTRM

ANSYS Fluent does not include a DTRM residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time a DTRM iteration is performed, ANSYS Fluent will print out the normalized radiation error for each DTRM radiation iteration. The normalized radiation error is defined as

$$E = \frac{\sum_{all\ radiating\ surfaces} \left(I_{new} - I_{old} \right)}{N \left(\sigma T^4 / \pi \right)} \tag{12.9}$$

where the error E is the maximum change in the intensity (I) at the current radiation iteration, normalized by the maximum surface emissive power, and N is the total number of radiating surfaces. Note that the default radiation convergence criterion, as noted in DTRM Solution Parameters (p. 879), defines the radiation calculation to be converged when E decreases to 10^{-3} or less.

12.3.9.6.4. Residual Reporting for the S2S Model

ANSYS Fluent does not include an S2S residual in its usual residual report that is issued after each iteration. The effect of radiation on the solution can be gathered, instead, via its impact on the energy field and the energy residual. However, each time an S2S iteration is performed, ANSYS Fluent will print out the normalized radiation error for each S2S radiation iteration. The normalized radiation error is defined as

$$E = \frac{\sum_{all\ radiating\ surface\ clusters} \left(J_{new} - J_{old} \right)}{N \sigma T^4} \tag{12.10}$$

where the error E is the maximum change in the radiosity (J) at the current radiation iteration, normalized by the maximum surface emissive power, and N is the total number of radiating surface clusters. Note that the default radiation convergence criterion, as noted in DTRM Solution Parameters (p. 879), defines the radiation calculation to be converged when E decreases to 10^{-3} or less.

12.3.9.6.5. Disabling the Update of the Radiation Fluxes

Sometimes, you may want to set up your ANSYS Fluent model with the radiation model active and then disable the radiation calculation during the initial calculation phase. For the P-1 and DO models, you can turn off the radiation calculation temporarily by deselecting **P1** or **Discrete Ordinates** in the **Equations** dialog box, which is accessed by right-clicking **Solution Controls** in the tree (under **Solution**) and clicking **Equations...** in the menu that opens. For the DTRM and the S2S model, there is no radiation calculation to disable in the **Equations** dialog box. You can instead set a very large number for **Energy**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Iterations per Radiation Iteration in the **Iteration Parameters** group box of the **Radiation Model** dialog box.

If you turn off the radiation calculation, ANSYS Fluent will skip the update of the radiation field during subsequent iterations, but will leave in place the influence of the current radiation field on energy sources due to absorption, wall heat fluxes, and so on. Turning the radiation calculation off in this way can therefore be used to initiate your modeling work with the radiation model inactive and/or to focus the computational effort on the other equations if the radiation model is relatively well converged.

12.3.10. Postprocessing Radiation Quantities

Information regarding postprocessing radiation quantities can be found in the following sections:

12.3.10.1. Available Variables for Postprocessing
12.3.10.2. Reporting Radiative Heat Transfer Through Boundaries
12.3.10.3. Overall Heat Balances When Using the DTRM
12.3.10.4. Displaying Rays and Clusters for the DTRM
12.3.10.5. Reporting Radiation in the S2S Model

12.3.10.1. Available Variables for Postprocessing

ANSYS Fluent provides radiation quantities that you can use in postprocessing when your model includes the solution of radiative heat transfer. You can generate graphical plots or alphanumeric reports of the following variables/functions:

In the **Radiation...** category:

- **Incident Radiation** (P-1, DO, and MC models)
- **Incident Radiation (Band n)** (non-gray P-1, non-gray DO, non-gray MC models)
- **Absorption Coefficient** (DTRM, P-1, DO, and Rosseland models)
- **Scattering Coefficient** (P-1, DO, and Rosseland models)
- **Refractive Index** (P–1, DO, and Rosseland models)
- **Radiation Temperature** (P-1, DO, and MC models)
- **Surface Cluster ID** (S2S model)
- **Volumetric Absorbed Radiation** (MC model)
- **Volumetric Emitted Radiation** (MC model)
- **Radiation Intensity.Normalized Std Deviation** (MC model)
- **Wall Irradiation Flux.Normalized Std Deviation** (MC model)

In the **Wall Fluxes...** category:

- **Radiation Heat Flux** (all radiation models)
- **Surface Incident Radiation** (S2S, DTRM, and DO models)
- **Absorbed Radiation Flux** (DO model, semi-transparent wall)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Reflected Radiation Flux** (DO model, semi-transparent wall)
- **Transmitted Radiation Flux** (DO model, semi-transparent wall)
- **Beam Irradiation Flux** (DO model, semi-transparent wall)

See Field Function Definitions (p. 1931) for definitions of these postprocessing variables. Note that in addition, incident radiation, transmitted, reflected and absorbed radiation flux are also available on a per-band basis for the non-gray DO model.

Important

- The sign convention on the radiative heat flux is such that the heat flux from the wall surface is a positive quantity.
- It is possible to export heat flux data on wall zones (including radiation) to a generic file that you can examine or use in an external program. See Exporting Heat Flux Data (p. 832) for details.
- Take care not to confuse **Incident Radiation** and **Surface Incident Radiation**. **Incident Radiation** is a volumetric quantity giving the total radiant load passing through the cell (in all directions), whereas **Surface Incident Radiation** is the total radiant load hitting the surface (which will subsequently be absorbed, transmitted and reflected). There is no direct means to report how much radiation has been absorbed/emitted/scattered in cells.

12.3.10.2. Reporting Radiative Heat Transfer Through Boundaries

You can use the **Flux Reports** dialog box to compute the radiative heat transfer through each boundary of the domain, or to sum the radiative heat transfer through all boundaries.

Results → Reports → Fluxes **Edit...**

See Fluxes Through Boundaries (p. 1911) for details about generating flux reports.

12.3.10.3. Overall Heat Balances When Using the DTRM

The DTRM yields a global heat balance and a balance of radiant heat fluxes only in the limit of a sufficient number of rays. In any given calculation, therefore, if the number of rays is insufficient you may find that the radiant fluxes do not obey a strict balance. Such imbalances are the inevitable consequence of the discrete ray tracing procedure and can be minimized by selecting a larger number of rays from each wall boundary.

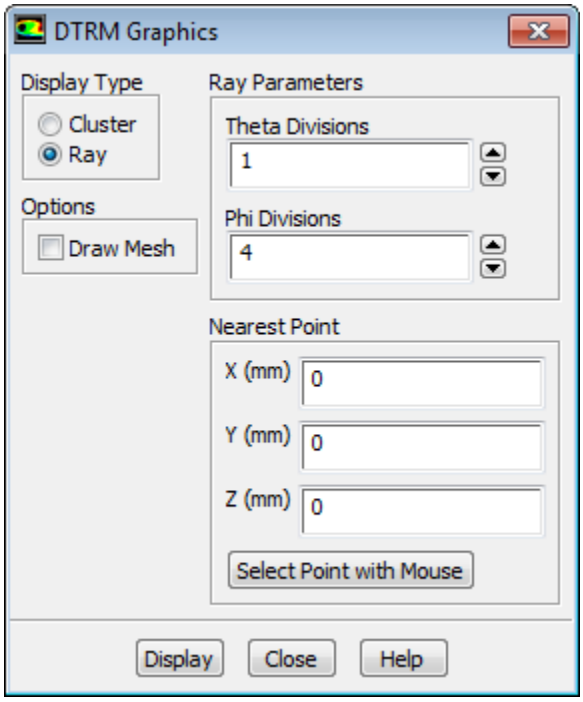
12.3.10.4. Displaying Rays and Clusters for the DTRM

When you use the DTRM, ANSYS Fluent allows you to display surface or volume clusters, as well as the rays that emanate from a particular surface cluster. You can use the **DTRM Graphics** dialog box (Figure 12.29: The DTRM Graphics Dialog Box (p. 884)) for all of these displays.

Postprocessing → Model Specific → DTRM Graphics...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.29: The DTRM Graphics Dialog Box



12.3.10.4.1. Displaying Clusters

To view clusters, select **Cluster** under **Display Type** and then select either **Surface** or **Volume** under **Cluster Type**.

To display all of the surface or volume clusters, select the **Display All Clusters** option under **Cluster Selection** and click the **Display** button.

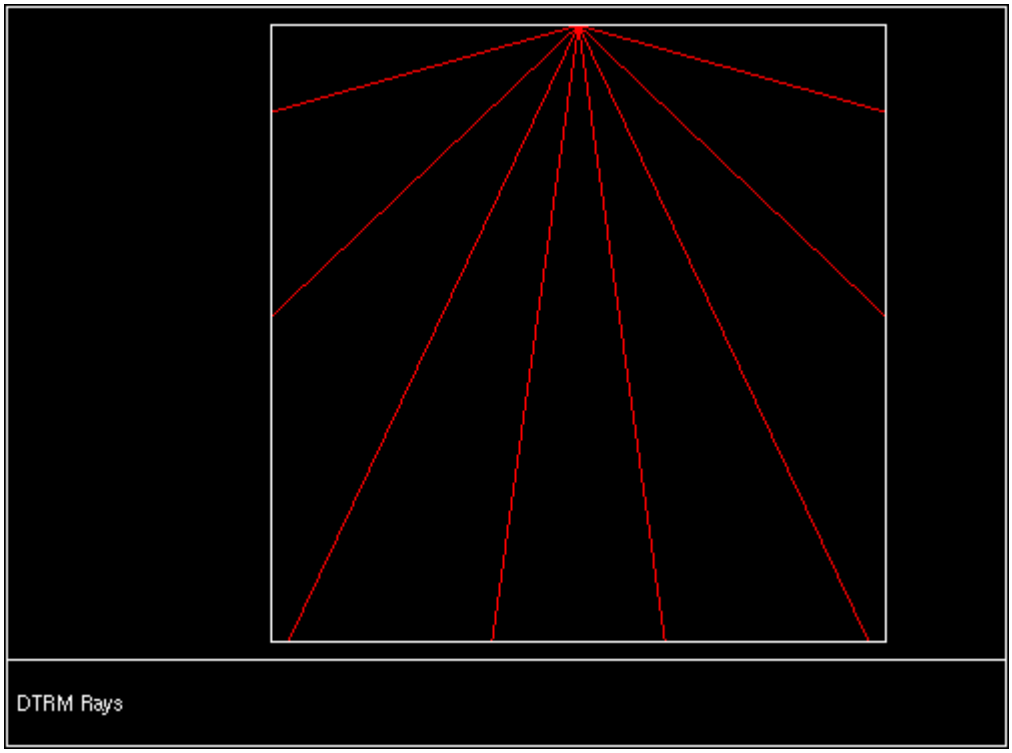
To display only the cluster (surface or volume) nearest to a specified point, deselect the **Display All Clusters** option and specify the coordinates under **Nearest Point**. You may also use the mouse to choose the nearest point. Click the **Select Point With Mouse** button and then right-click a point in the graphics window.

12.3.10.4.2. Displaying Rays

To display the rays emanating from the surface cluster nearest to the specified point, select **Ray** under **Display Type**. Set the appropriate values for **Theta** and **Phi Divisions** under **Ray Parameters** (see Setting Up the DTRM (p. 848) for details), and then click the **Display** button. Figure 12.30: Ray Display (p. 885) shows a ray plot for a simple 2D geometry.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.30: Ray Display



12.3.10.4.3. Including the Mesh in the Display

For some problems, especially complex 3D geometries, you may want to include portions of the mesh in your ray or cluster display as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with displaying the rays. This is accomplished by enabling the **Draw Mesh** option in the **DTRM Graphics** dialog box. The **Mesh Display** dialog box will appear automatically when you enable the **Draw Mesh** option, and you can set the mesh display parameters there. When you click **Display** in the **DTRM Graphics** dialog box, the mesh display, as defined in the **Mesh Display** dialog box, will be included in the ray or cluster display.

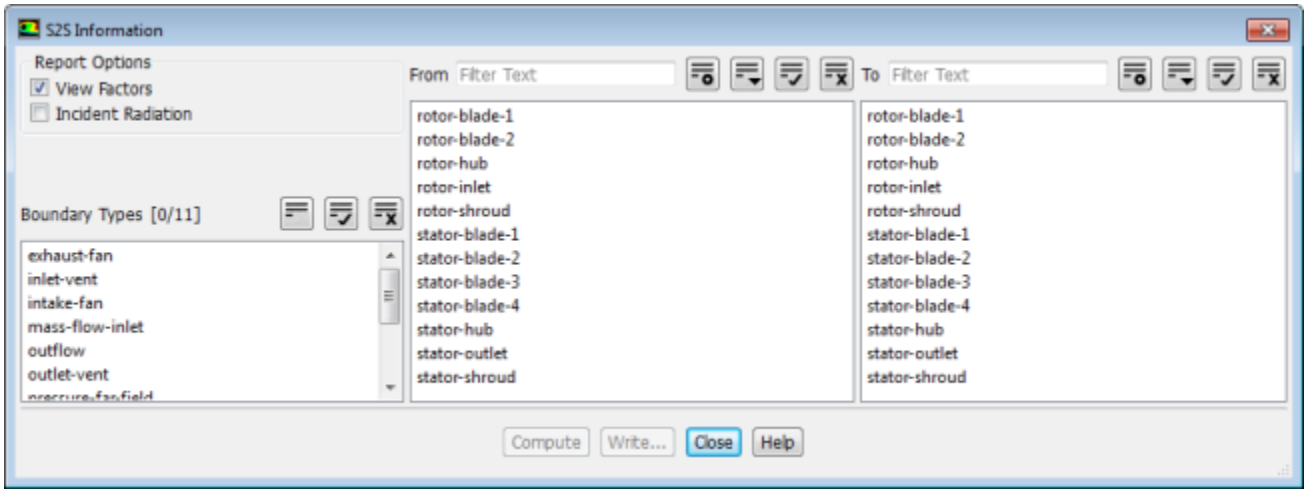
12.3.10.5. Reporting Radiation in the S2S Model

When you use the S2S model, ANSYS Fluent allows you to view the values of the view factor and radiation emitted from one zone to any other zone. You can use the **S2S Information** dialog box (Figure 12.31: The S2S Information Dialog Box (p. 886)) to generate a report of these values in the console or as a separate file.

Postprocessing → Model Specific → S2S Information...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.31: The S2S Information Dialog Box



The steps for generating the report are as follows:

1. Specify the values in which you are interested by selecting **View Factors** and/or **Incident Radiation**.

2. Choose the zones for which you would like data by selecting them in the lists under **From** and **To** (at least one zone must be selected under each list). To select all of the zones of a particular type, click that category in the list under **Boundary Types**.

3. Specify how you would like to present the data. To report the values in the console, click the **Compute** button. To write the data as an S2S Info File (`.sif` format), click the **Write...** button and enter a file name in The Select File Dialog Box (p. 19).

The following is an example of how the data is presented:

```
S2S Information
From wall1 to:
                    View factor       Incident Radiation
          wall1          0.0000                  0.0000
          wall2          0.2929             171387.7813
          wall3          0.2929             155305.7969
          wall4          0.4142              29055.9023

From wall2 to:
                    View factor       Incident Radiation
          wall1          0.2929             306451.9688
          wall2          0.0000                  0.0000
          wall3          0.4142             214195.0938
          wall4          0.2929              19153.2715
```

Note that the header listed above (`S2S Information`) is not displayed in the console.

12.3.11. Solar Load Model

ANSYS Fluent provides a solar load model that can be used to calculate radiation effects from the sun's rays that enter a computational domain. Two options are available for the model: solar ray tracing and DO irradiation. The ray tracing approach is a highly efficient and practical means of applying solar loads as heat sources in the energy equations. In cases where you want to use the discrete ordinates (DO) model to calculate radiation effects within the domain, an option is available to supply outside beam direction and intensity parameters directly to the DO model. The solar load model includes a solar calculator utility that can be used to construct the sun's location in the sky for a given time-of-day, date,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and position. Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

12.3.11.1. Introduction

Typical applications that are well-suited for solar load simulations include the following:

- automotive climate control (ACC) applications
- human comfort modeling applications in buildings

The effects of solar loading are needed in many ACC applications, where the temperature, humidity, and velocity fields around passengers (and drivers) are desired. ACC systems are tested for their capacity to cool down passenger compartments after they have been "soaked" in intense solar radiation. ANSYS Fluent's solar load model will enable you to simulate solar loading effects and predict the time it will take to reasonably cool down the cabin of a car that has been exposed to solar radiation, as well as predict the time interval needed to lower the temperature in specified points and areas within the domain.

In the analysis of buildings, solar loading provides a significant burden on the cooling requirement in warm climates, particularly where architects want to use the aesthetics of glazed facades. Even in cooler climates, solar loading can provide a burden during warmer seasons where modern buildings are well insulated against thermal loss during winter months. As well as providing an engineer with a practical tool for determining the solar heating effect inside a building, ANSYS Fluent's solar load model will allow the solar transmission through all glazed surfaces to be determined over the course of a day, allowing important decisions to be made before undertaking any flow studies. ANSYS Fluent's solar load model also allows you to simulate porous blinds, which can transmit a portion of the solar radiation while also allowing fluid flow.

12.3.11.2. Solar Ray Tracing

The solar load model's ray tracing algorithm can be used to predict the direct illumination energy source that results from incident solar radiation. It takes a beam that is modeled using the sun position vector and illumination parameters, applies it to any or all wall, porous jump, and inlet/outlet boundary zones that you specify, performs a face-by-face shading analysis to determine well-defined shadows on all boundary faces and interior walls, and computes the heat flux on the boundary faces that results from the incident radiation.

Important

The solar ray tracing model includes only boundary zones that are adjacent to fluid zones in the ray tracing calculation. Therefore, boundary zones that are attached to solid zones are treated as transparent and are not included in the ray tracing algorithm.

The resulting heat flux that is computed by the solar ray tracing algorithm is coupled to the ANSYS Fluent calculation via a source term in the energy equation. The heat sources are added directly to computational cells bordering each face and are assigned to adjacent cells in the following order: shell conduction cells, solid cells, and fluid cells. Heat sources are assigned to one of these types of adjacent cells, only. You can choose to override this order and include adjacent fluid cells in the solar load calculation by issuing a command in the text user interface (see Text Interface-Only Commands (p. 907) for details). Note that the sun position vector and solar intensity can be entered either directly by you or computed from the solar calculator. Direct and diffuse irradiation parameters can also be specified using a user-defined function (UDF) and hooked to ANSYS Fluent in the **Radiation Model** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The solar ray tracing option allows you to include the effects of direct solar illumination as well as diffuse solar radiation in your ANSYS Fluent model. A two-band spectral model is used for direct solar illumination and accounts for separate material properties in the visible and infrared bands. A single-band hemispherical-averaged spectral model is used for diffuse radiation. Opaque materials are characterized in terms of two-band absorptivities. A semi-transparent material requires specification of absorptivity and transmissivity. Values that you specify for transmissivity and absorptivity are defined for normal incident rays. ANSYS Fluent recomputes/interpolates these values for the given angle of incidence.

The solar ray tracing algorithm also accounts for internal scattered and diffusive loading. The reflected component of direct solar irradiation is tracked. A fraction of this radiative heat flux, called internally scattered energy is applied to all the surfaces participating in the solar load calculation, weighted by area. The internally scattered energy depends on the scattering fraction that is specified in the TUI, whose default value is 1. Depending on the reflectivity of the primary surface, the scattering fraction can be responsible for the inclusion (or exclusion) of a large amount of radiation within the rest of the domain.

Also included as internally scattered energy is the contribution of the transmitted component of diffuse solar irradiation (which enters a domain through semi-transparent walls depending upon the hemispherical transmissivity). The total value of internally scattered energy is reported to the ANSYS Fluent console. The ambient flux is obtained by dividing the internally scattered energy by the total surface area of the faces participating in the solar load calculation.

Note that **Solar Ray Tracing** is *not* a participating radiation model. It does not deal with emission from surfaces, and the reflecting component of the primary incident load is distributed uniformly across all surfaces rather than being local to the surfaces reflected to. If surface emission is an important factor in your case then you can consider implementing a radiation model (for example, P-1) in conjunction with **Solar Ray Tracing**.

Note the following limitation when using the solar ray tracing model:

- Non-conformal interfaces are not supported with the solar ray tracing model.

12.3.11.2.1. Shading Algorithm

The shading calculation that is used for solar ray tracing is a straightforward application of vector geometry. A ray is traced from the centroid of a test face in the direction of the sun. Every other face is checked to determine if the ray intersects the candidate face and if the candidate face is in front of the test face. If both conditions are met, then an opaque face completely shades the test face. A semi-transparent face attenuates the incident energy.

A Barycentric coordinate formulation is used to construct triangle-ray intersections. A quadrilateral ray intersection method is used to handle the case when model surfaces contain quadrilaterals. A quad-tree preprocessing step is applied to reduce the ray tracing algorithm complexity that can lead to long run times for 10^4 faces and greater. The quad-tree refinement factor can be modified in the text interface. The default value of this parameter is 7, which is sufficient to cover the entire spectrum of mesh sizes between one cell and five million cells. If the mesh is greater than five million cells, an increase in this parameter would reduce the CPU time needed to compute the solar loads.

12.3.11.2.2. Glazing Materials

Incident solar radiation can be applied to glass and plastic glazing materials of various types at wall boundaries, and the effects of coated glazings modeled using the solar ray tracing algorithm. To model solar optical properties, you will need to specify the transmissivity and reflectivity of the material in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Wall boundary conditions dialog box. You can obtain these values from the glass (or plastic) manufacturer or use data from another source (for example, ASHRAE Handbook).

Glazing optical properties are dependent on incident angle, and the variation is significant for an incident angle greater than 40 degrees. As the incident angle increases from zero, transmissivity decreases, reflectivity increases, and absorptivity increases initially due to lengthened optical path, and then decreases as more incident radiation is reflected. The shape of the property curve varies with glass type and thickness. This difference is more pronounced for coated glass or for a multiple-pane glazing system. It cannot be assumed that all glazing systems have a universal angular dependence.

For coated glazings, the spectral transmissivity and reflectivity at any incident angle are approximated in the solar load model from the normal angle of incidence [31] (p. 2888).

Transmissivity is given by

$$T(\theta,\lambda)=T(0,\lambda)Tref(\theta) \tag{12.11}$$

where

$$Tref(\theta)=a0+a1cos(\theta)+a^2cos(\theta^2)+a3cos(\theta^3)+a4cos(\theta^4) \tag{12.12}$$

Reflectivity is given by

$$R(\theta,\lambda)=R(0,\lambda)[1-Rref(\theta)]+Rref(\theta) \tag{12.13}$$

where

$$Rref(\theta)=b0+b1cos(\theta)+b^2cos(\theta^2)+b3cos(\theta^3)+b4cos(\theta^4)-Tref(\theta) \tag{12.14}$$

The constants used in Equation 12.11 (p. 889) and Equation 12.13 (p. 889) are for coated glazings and are taken from Finlayson and Arasteh. [31] (p. 2888). The normal transmissivity and reflectivity, $T(0,\lambda)$ and $R(0,\lambda)$ are specified in the **Wall** boundary conditions dialog box.

12.3.11.2.3. Inputs

The following inputs are required for the solar ray tracing algorithm:

- sun direction vector
- direct solar irradiation
- diffuse solar irradiation
- spectral fraction
- direct and IR absorptivity (opaque wall)
- direct and IR absorptivity and transmissivity (semi-transparent wall and porous jump)
- diffuse hemispherical absorptivity and transmissivity (semi-transparent wall)
- solar transmissivity factor
- quad tree refinement factor
- scattering fraction

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ground reflectivity

The sun direction vector is the direction vector looking to the sun, from which the direct irradiation will be incident. You can enter the vector components (**X**, **Y**, **Z**) and the direct and diffuse solar irradiation fluxes in the **Radiation Model** dialog box, or you can have these parameters derived from the solar calculator. These irradiation fluxes can also be specified using a user-defined function (User-Defined Functions (UDFs) for Solar Load (p. 894)). The spectral fraction is the final input in the **Radiation Model** dialog box. This defines the split of visible and infra-red (shortwave and longwave respectively) radiation, specifically the fraction of the direct irradiation flux that is in the visible band. These quantities can also be defined through the text interface.

The scattering fraction defines the amount of non-absorbed radiation that will be distributed (uniformly) across all participating surfaces. This is required as the solar load model does not track the rays beyond the first opaque surface. Therefore, a highly glazed space where incident radiation is likely to be reflected back out will have a low value. Conversely, a predominantly opaque (wall-bounded) space where reflected radiation is likely to be incident upon (and ultimately absorbed by) other opaque surfaces will have a high value. This parameter is defined through the text interface only, taking a default value of 1.0:

`define` → `models` → `radiation` → `solar-parameters` → `scattering-fraction`

The ground reflectivity is used by the solar calculator to compute the background diffuse radiation intensity component contributed to by radiation reflected off the ground. This should be based on typical figures for the surface reflectivity of the outside ground surfaces. By default this is set to 0.2, but can be adjusted through the text-interface:

`define` → `models` → `radiation` → `solar-parameters` → `ground-reflectivity`

The quad-tree-refinement parameter determines the level of detail used by the shading algorithm. By default this is set to 7 which will generally work well, but can lie between 0 and 10. This is defined only through the text interface:

`define` → `models` → `radiation` → `solar-parameters` → `quad-tree-refinement`

Further details on the text interface-only entries is provided later in this section (see Text Interface-Only Commands).

The absorptivity and transmissivity parameters related to a wall or porous jump are entered in the **Wall** (under the **Radiation** tab) or **Porous Jump** boundary condition dialog box, respectively, for the particular boundary zones you want to participate in solar ray tracing. On flow boundaries you have a solar transmissivity factor to allow you to attenuate the incoming solar flux, for example, set to 1 for a fully open inlet or set to 0 for a light obscuring louvered inlet.

12.3.11.3. DO Irradiation

The solar load model's discrete ordinates (DO) irradiation option provides you with an easy means of applying a solar load directly to the DO model. Unlike the ray tracing solar load option, the DO irradiation method does not compute heat fluxes and apply them as heat sources to the energy equation. Instead, the irradiation flux is applied directly to semi-transparent walls (which you specify) as a boundary condition, and the radiative heat transfer is derived from the solution of the DO radiative transfer equation.

The following inputs are required for DO irradiation at semi-transparent walls:

- direct irradiation

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- diffuse irradiation
- beam direction
- beam width
- diffuse fraction

In the **Wall** boundary condition dialog box for each semi-transparent wall you want to participate in DO irradiation, you can specify that the beam direction, direct irradiation, and diffuse irradiation be derived from the solar parameters (for example, solar calculator) that you set (or compute) in the **Radiation Model** dialog box. This is done by checking the **Use Beam Direction from Solar Load Model Settings** and **Use Direct and Diffuse Irradiation from Solar Load Model Settings** boxes. When selected, ANSYS Fluent sets the beam width (the angle subtended by the sun) to the default value of 0.53 degrees for DO irradiation.

Important

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (for example, radiation coming from the sun), while the sun direction vector in the solar load model points to the sun. Incident radiation and the sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.

12.3.11.4. Solar Calculator

ANSYS Fluent provides a solar calculator that can be used to compute solar beam direction and irradiation for a given time, date, and position. These values can be used as inputs to the solar ray tracing algorithm or as semi-transparent wall boundary conditions for discrete ordinates (DO) irradiation.

12.3.11.4.1. Inputs/Outputs

Inputs needed for the solar calculator are:

- global position (latitude, longitude, time zone)
- starting date and time
- mesh orientation
- solar irradiation method
- sunshine factor

Global position consists of latitude, longitude, and time zone (relative to GMT). The time of day for a transient simulation is the starting time plus the flow-time. For mesh orientation, you will need to specify the North and East direction vector in the CFD mesh. The default solar irradiation method is Fair Weather Conditions. Alternatively, you can choose the Theoretical Maximum method. The sunshine factor is simply a linear reduction factor for the computed incident load that allows for cloud cover to be accounted for, if appropriate.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can specify these inputs in the **Solar Calculator** dialog box that is accessible from the **Radiation Model** dialog box (Figure 12.35: The Solar Calculator Dialog Box (p. 898)). Alternatively, you can enter the parameters using text interface commands (Additional Text Interface Commands (p. 909)).

The following values are computed by the solar calculator and are displayed in the console whenever the solar calculator is used:

- sun direction vector
- sunshine fraction
- direct normal solar irradiation at earth's surface
- diffuse solar irradiation - vertical and horizontal surface
- ground reflected (diffuse) solar irradiation - vertical surface

Direct normal solar irradiation is computed using the ASHRAE Fair Weather Conditions method, when this option is selected in the solar calculator. Note: Equation 20 and Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals. The theoretical maximum values for direct normal solar irradiation and diffuse solar irradiation are computed using NREL's Theoretical Maximum method, when this option is selected. In practice, these values are unlikely to be experienced due to atmospheric conditions.

ANSYS Fluent computes the diffuse solar irradiation components (vertical and horizontal) internally for each face in the domain. When the Theoretical Maximum method is chosen, these diffuse irradiation values provide estimates for the maximum vertical and horizontal surface effects.

12.3.11.4.2. Theory

ANSYS Fluent provides two options for computing the solar load: Fair Weather Conditions method and Theoretical Maximum method. Although these methods are similar, there is a key difference. The Fair Weather Conditions method imposes greater attenuation on the solar load, which is representative of atmospheric conditions that are fair–but not completely clear.

The equation for normal direct irradiation applying the Fair Weather Conditions Method is taken from the ASHRAE Handbook:

$$Edn=\frac{A}{e^{\frac{B}{\sin(\beta)}}} \tag{12.15}$$

where A and B are apparent solar irradiation at air mass $m=0$ and atmospheric extinction coefficient, respectively. These values are based on the earth's surface on a clear day. β is the solar altitude (in degrees) above the horizontal.

The equation for direct normal irradiation that is used for the Theoretical Maximum Method is taken from NREL's Solar Position and Intensity Code (Solpos):

$$Edn=S_{etrn}S_{unprime} \tag{12.16}$$

where S_{etrn} is the top of the atmosphere direct normal solar irradiance and $S_{unprime}$ is the correction factor used to account for reduction in solar load through the atmosphere.

The calculation for the diffuse load in the solar model is based on the approach suggested in the 2001 ASHRAE Fundamental Handbook (Chapter 20, Fenestration). The equation for diffuse solar irradiation on a vertical surface is given by:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$Ed = CYEdn \tag{12.17}$$

where C is a constant whose values are given in Table 7 from Chapter 30 of the 2001 ASHRAE Handbook of Fundamentals, Y is the ratio of sky diffuse radiation on a vertical surface to that on a horizontal surface (calculated as a function of incident angle), and Edn is the direct normal irradiation at the earth's surface on a clear day.

The equation for diffuse solar irradiation for surfaces other than vertical surfaces is given by:

$$Ed = CEdn\frac{\left(1+\cos\varepsilon\right)}{2} \tag{12.18}$$

where ε is the tilt angle of the surface (in degrees) from the horizontal plane.

The equation for ground reflected solar irradiation on a surface is given by:

$$Er = Edn\left(C+\sin\beta\right)\rho_g\frac{\left(1-\cos\varepsilon\right)}{2} \tag{12.19}$$

where ρ_g is the ground reflectivity. The total diffuse irradiation on a given surface will be the sum of Ed and Er when the input for diffuse solar radiation is taken from the solar calculator. Otherwise, if the `constant` option is selected in the **Radiation** dialog box, then the total diffuse irradiation will be the same as specified in the dialog box.

12.3.11.4.3. Computation of Load Distribution

In calculating the solar load that will be incident on each surface, it is necessary to distinguish between the calculation of diffuse and direct solar loads. A direct load will be tracked from participating transmissive boundary surfaces and non-participating boundary surfaces, the former provides some opportunity to attenuate the incoming flux by absorption and reflection, while the non-participating surfaces allow the flux to enter without any drop in intensity. The direct load is then tracked through the model space until it is incident on an opaque surface, or it exists through a transmissive or non-participating boundary zone. During its passage, its intensity will be attenuated as it passes through participating semi-transparent internal walls, where some radiation may be absorbed and some may be reflected. The total amount of direct radiation that is reflected at internally facing surfaces will be added to the scattered radiation budget for further use later.

The diffuse load originates at participating transmissive boundary surfaces. It is these surfaces that permit diffuse radiation to enter, irrespective of their orientation relative to the direction vector. For each transmissive surface, some of the incoming diffuse load may be immediately absorbed and/or reflected to the outside. The rest is assumed to be transmitted inside and summed from all of these surfaces to give an initial diffuse budget. Onto this budget is added a fraction of the previously computed scattered radiation from the direct load, the fraction used is defined as an input to the model. This provides the total diffuse load. This is then uniformly distributed across all surfaces that are participating in the solar calculation, irrespective of whether they are opaque or semi-transparent. There is no scope to define local absorptivity for this distribution and no biasing with regards proximity to transmissive surfaces. Note that a non-participating boundary zone will allow direct load to enter the model space but will not provide an incoming quantity of diffuse load.

Note that the solar flux that is externally incident on an opaque surface will be completely disregarded, for example solar load on an opaque roof of a model whose internals only are modeled will not be included as a heat gain. Instead, this heat gain should be manually calculated and applied as a thermal condition, typically using a fixed heat flux or a radiation/mixed condition.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

12.3.11.5. Using the Solar Load Model

When you want to run a steady-state solution with solar load enabled, you simply set up the solar load model (Setting Up the Solar Load Model (p. 894)) and boundary conditions (Setting Boundary Conditions for Solar Loading (p. 899)) for your case, and then run the simulation. The solution data file will contain the solar fluxes that you can use for postprocessing. For a steady-state solution, the solar loads are computed on initialization. If you want to initially solve a case without solar loading (say, for stability) and then add the effects of solar loading afterward, you will need to enable the solar load model through the text user interface (TUI).

Important

Note that you can compute the solar load at any time once you have set up the model by using the `sol-on-demand` text interface command (see Additional Text Interface Commands (p. 909) for details).

When you want to run a transient solar load simulation, the process is the same as for the steady-state case but you will need to specify the additional **Time Steps per Solar Load Update** parameter in the **Radiation Model** dialog box. ANSYS Fluent will re-compute the sun position and irradiation and update solar loads with this specified frequency.

Important

Note that parallel simulations involving the solar load model are set up and computed using the same steps as in serial.

12.3.11.5.1. User-Defined Functions (UDFs) for Solar Load

You can write a user-defined function (UDF) to specify direct and diffuse solar intensity using the `DEFINE_SOLAR_INTENSITY` macro. See `DEFINE_SOLAR_INTENSITY` in the for more information. After it is interpreted or compiled, you can hook your intensity UDF for direct or diffuse solar irradiation by selecting `user-defined` in the drop-down lists for these parameters in the **Radiation Model** dialog box. See Step 2 in Setting Up the Solar Load Model (p. 894) for details.

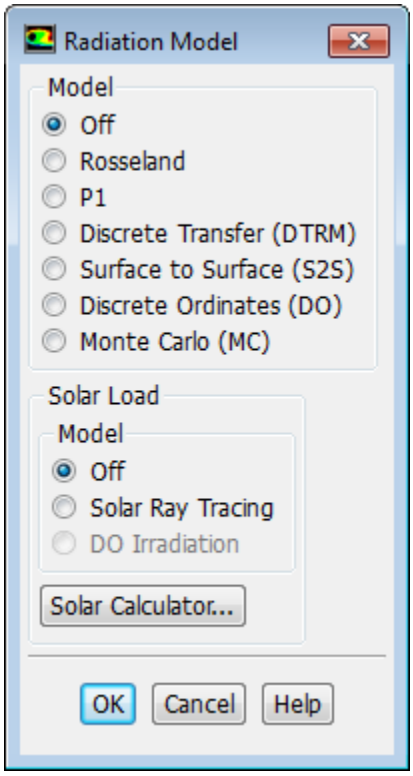
12.3.11.5.2. Setting Up the Solar Load Model

The solar load model is enabled in the **Radiation Model** dialog box (Figure 12.32: The Radiation Model Dialog Box (p. 895)).

Setup → Models → Radiation → Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.32: The Radiation Model Dialog Box



Important

Solar load is available in the 3D solver only, and can be used to model steady and unsteady flows.

The solar load model has two options: **Solar Ray Tracing** and **DO Irradiation**. **Solar Ray Tracing** can be applied as a stand-alone solar loading model, or it can be used in conjunction with one of the ANSYS Fluent radiation models (P1, Rosseland, Discrete Transfer, Surface-to-Surface, Discrete Ordinates). **DO Irradiation** is available only when the **Discrete Ordinates (DO)** radiation model is enabled.

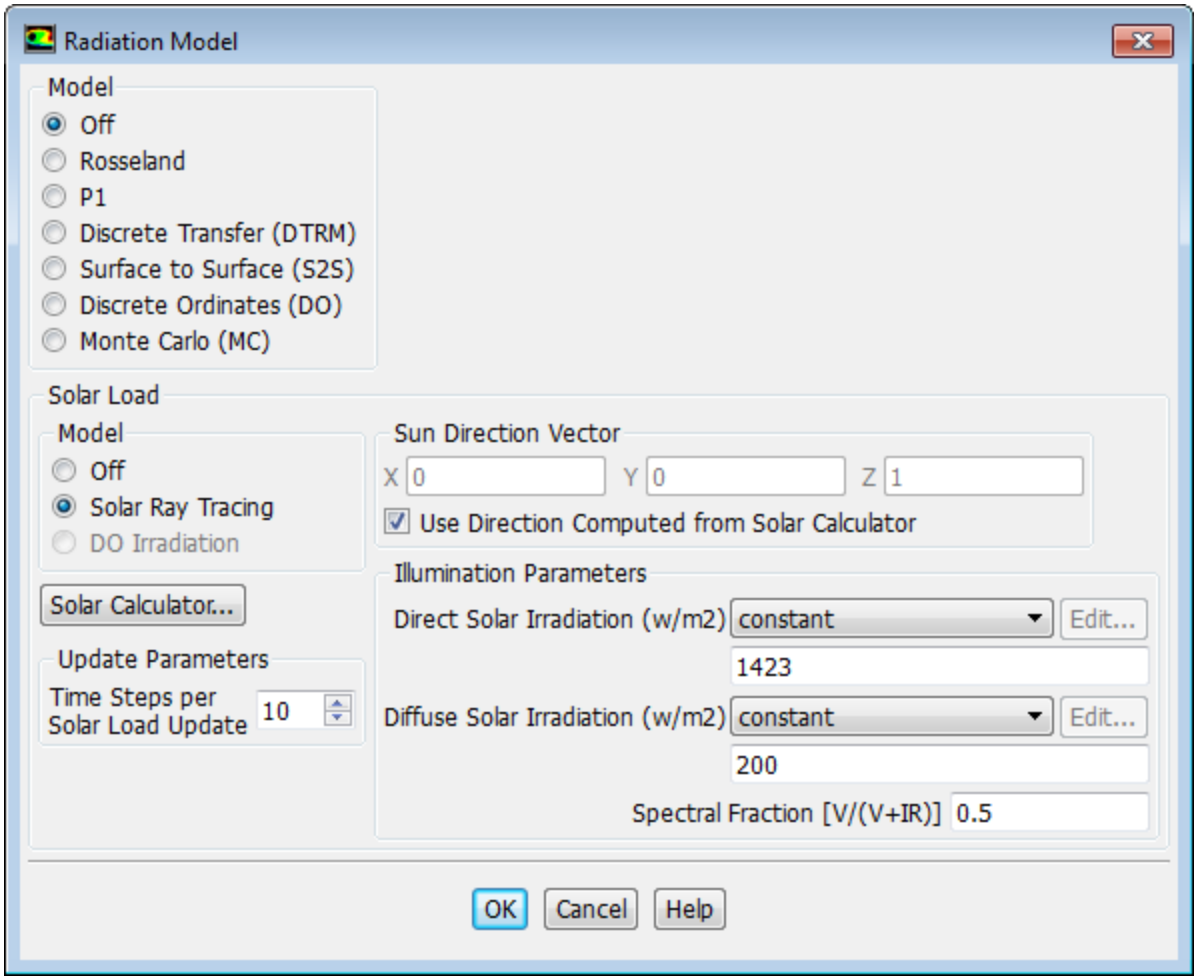
To set up the solar load model, perform the following steps:

1. Enable the solar load model in the **Radiation Model** Dialog Box.

   a. To enable the solar ray tracing algorithm, select **Solar Ray Tracing** under **Solar Load** (Figure 12.33: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option) (p. 896)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

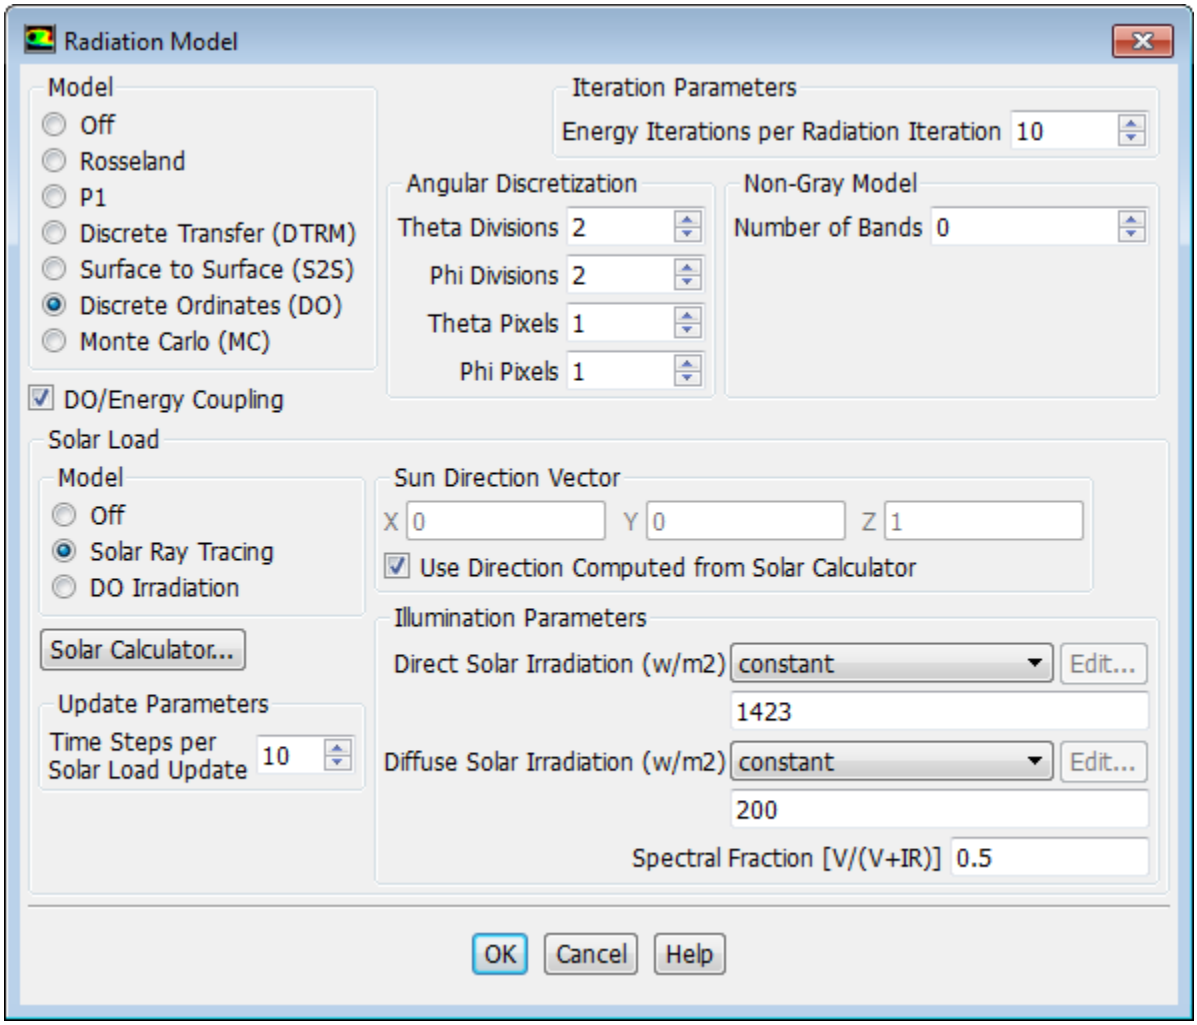
Figure 12.33: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option)



b. To enable the DO irradiation option, first select **Discrete Ordinates** under **Model**, and then select **DO Irradiation** under **Solar Load** (Figure 12.34: The Radiation Model Dialog Box (with Solar Load Model DO Irradiation Option) (p. 897)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.34: The Radiation Model Dialog Box (with Solar Load Model DO Irradiation Option)



2. Define the solar parameters.

   a. Enter values for the **X**, **Y**, and **Z** components of the **Sun Direction Vector**. Alternatively, you can choose to have this vector computed from the solar calculator by enabling the **Use Direction Computed from Solar Calculator** option.

   b. Specify the illumination parameters.

      i. Enter a value for **Direct Solar Irradiation** under **Illumination Parameters**. This parameter is the amount of energy per unit area in W / m^2 due to direct solar irradiation. This value may depend on the time of year and the clearness of the sky. Make your selection in the drop-down list next to **Direct Solar Irradiation** and either enter a **constant** value, have the value computed from the **solar calculator**, or specify it using a **user-defined function**. (For more information on writing solar intensity UDFs, see `DEFINE_SOLAR_INTENSITY` in the Fluent Customization Manual.) For transient simulations, you have the additional option of specifying a time-dependent **piecewise-linear** and **polynomial** profile for direct solar irradiation.

      ii. Enter a value for **Diffuse Solar Irradiation**, which is the amount of energy per unit area in W / m^2 due to diffuse solar irradiation. This value may depend on the time of year, the clearness of the sky, and also on ground reflectivity. Make your selection in the drop-down list next to **Diffuse Solar Irradiation** and either enter a **constant** value, have the value computed from the **solar calculator**,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

or specify it using a **user-defined function**. (For more information on writing solar intensity UDFs, see DEFINE_SOLAR_INTENSITY in the .) For transient simulations, you have the additional option of specifying a time-dependent **piecewise-linear** and **polynomial** profile for diffuse solar irradiation.

iii. If you are using the **Solar Ray Tracing** solar load model (Figure 12.33: The Radiation Model Dialog Box (With Solar Load Model Solar Ray Tracing Option) (p. 896)), then you will need to enter a value for **Spectral Fraction**. The spectral fraction is the fraction of incident solar radiation in the visible part of the solar radiation spectrum. The spectral fraction is not used for DO irradiation since the DO implementation is intended only for a single band.

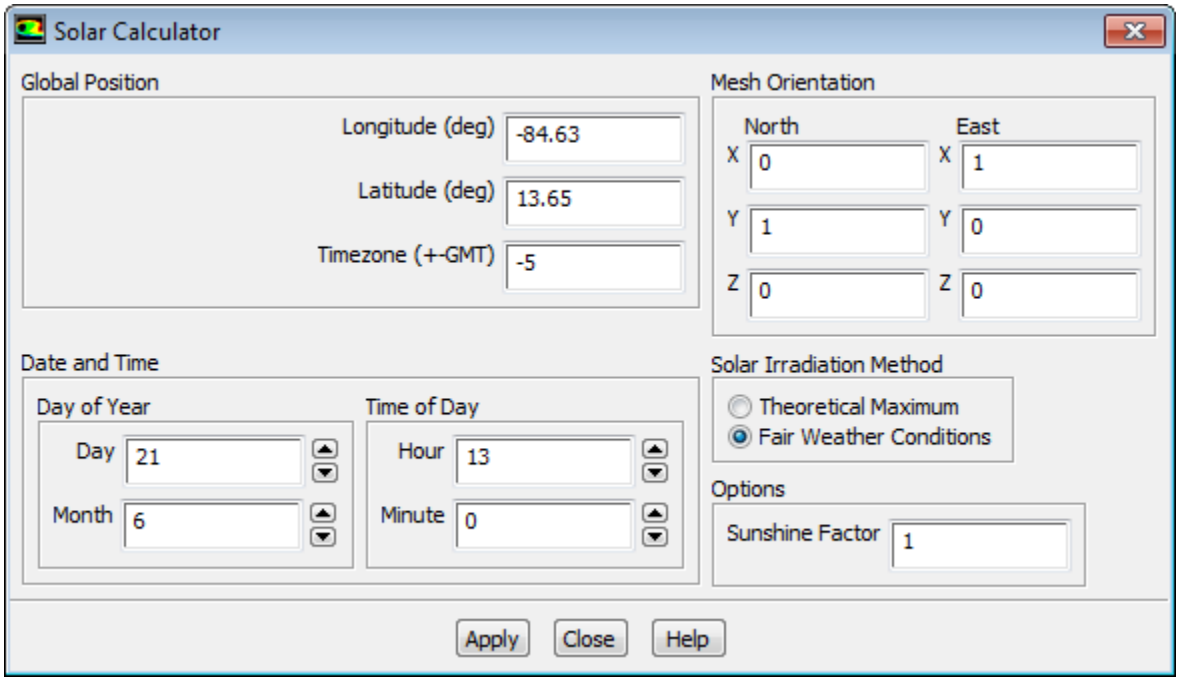
$$\text{Spectral Fraction} = \frac{V}{V+IR} \tag{12.20}$$

where V is the visible incident solar radiation, and $V+IR$ is the total incident solar radiation (visible plus infrared).

3. Use the solar calculator to compute solar beam direction and irradiation.

a. Click **Solar Calculator...** in the **Radiation Model** dialog box to open the **Solar Calculator** dialog box (Figure 12.35: The Solar Calculator Dialog Box (p. 898)).

Figure 12.35: The Solar Calculator Dialog Box



b. In the **Solar Calculator** dialog box, define the **Global Position** by the following parameters:

i. Enter a real number in degrees for **Longitude**. Values may range from -180 to 180 where negative values indicate the Western hemisphere and positive values indicate the Eastern hemisphere.

ii. Enter a real number for **Latitude** in degrees. Values can range from -90° (the South Pole) to 90° (the North Pole), with 0° defined as the equator.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iii. Enter an integer for **Timezone** that is the local time zone in hours relative to Greenwich Mean Time (+-GMT). This value can range from $+12$ to -12.

Important

Note that you must specify all three **Global Position** parameters for the solar calculator.

---

c. Define the local **Date and Time** by the following parameters:

i. Enter an integer for **Day** and **Month** under **Day of Year**.

ii. Enter an integer for **Hour** that ranges from 0 to 24 under **Time of Day**. Enter an integer or floating point number for **Minute**.

The time of day is based on a 24-hour clock: 0 hours and 0 minutes corresponds to 12:00 a.m. and 23 hours 59.99 min corresponds to 11:59.99 p.m. For example, if the local time was 12:01:30 a.m., you would enter `0` for **Hour** and `1.5` for **Minute**. If the local time was 4:17 p.m., you would enter `16` for **Hour** and `17` for **Minute**.

d. Define the **Mesh Orientation** as the vectors for North and East in the CFD mesh system of coordinates.

e. Select the appropriate **Solar Irradiation Method**. The **Fair Weather Conditions** is the default method.

f. Enter an integer for **Sunshine Fraction** (default = 1).

g. Click **Apply**.

The solar calculator output parameters are computed and the results are reported in the console. The default values are shown below:

```
Fair Weather Conditions:
 Sun Direction Vector: X: -0.0785396, Y: 0.170758, X: 0.982178
 Sunshine Fraction: 1
 Direct Normal Solar Irradiation (at Earth's surface) [W/m^2]:
 881.635
 Diffuse Solar Irradiation - vertical surface: [W/m^2]:
 152.107
 Diffuse Solar Irradiation - horizontal surface: [W/m^2]:
 118.727
 Ground Reflected Solar Irradiation - vertical surface: [W/m^2]:
 96.4649
```

4. For transient simulations, enter the **Time Steps Per Solar Load Update** under **Update Parameters**. The number of time steps that you specify will direct the ANSYS Fluent solver to update the solar load data for the specified flow-time intervals in the unsteady solution process.

12.3.11.5.3. Setting Boundary Conditions for Solar Loading

Once you have defined the solar parameters for the solar load model (Setting Up the Solar Load Model (p. 894)), you will need to set up boundary conditions for boundary zones that will participate in solar loading. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Boundary Conditions

12.3.11.5.4. Solar Ray Tracing

Note

Solar ray tracing is designed to be applied to your geometrical information, therefore, you must include every side of the external, or outer, enclosure/boundary for ray-tracing purposes, unless you expect that solar irradiation cannot enter through such boundaries. If you exclude any internal zone from the solar load computation, then this would mean that the resulting obstruction or blockage has been removed which would also be equivalent to a transparent surface. Excluded walls will also not participate in the computation of scattered energy by the solar load model and, therefore, do not gain any heat from scattered energy.

1. Set the boundary condition for each inlet and exit boundary zone that you want to include in solar loading.

   a. Open the inlet or exit boundary condition dialog box (for example, **Velocity Inlet**) and click the **Radiation** tab (Figure 12.36: The Velocity Inlet Dialog Box (p. 900)).

   Figure 12.36: The Velocity Inlet Dialog Box

   b. Enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default). If you deactivate solar ray tracing by disabling this option the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. Enter a value between 0 and 1 for the **Solar Transmissivity Factor**. This will allow you to control the amount of solar irradiation entering the domain. By reducing the solar transmissivity factor from 1 to 0.5, you can effectively cut the total internal energy source entering the domain by half.

> **Important**
>
> Note that the solar transmissivity factor is applied to both direct and diffuse solar irradiation components.

d. Click **OK**.

2. Set the boundary condition for each wall boundary zone that you want to include in solar loading.

   a. Open a **Wall** boundary condition dialog box and click the **Radiation** tab.

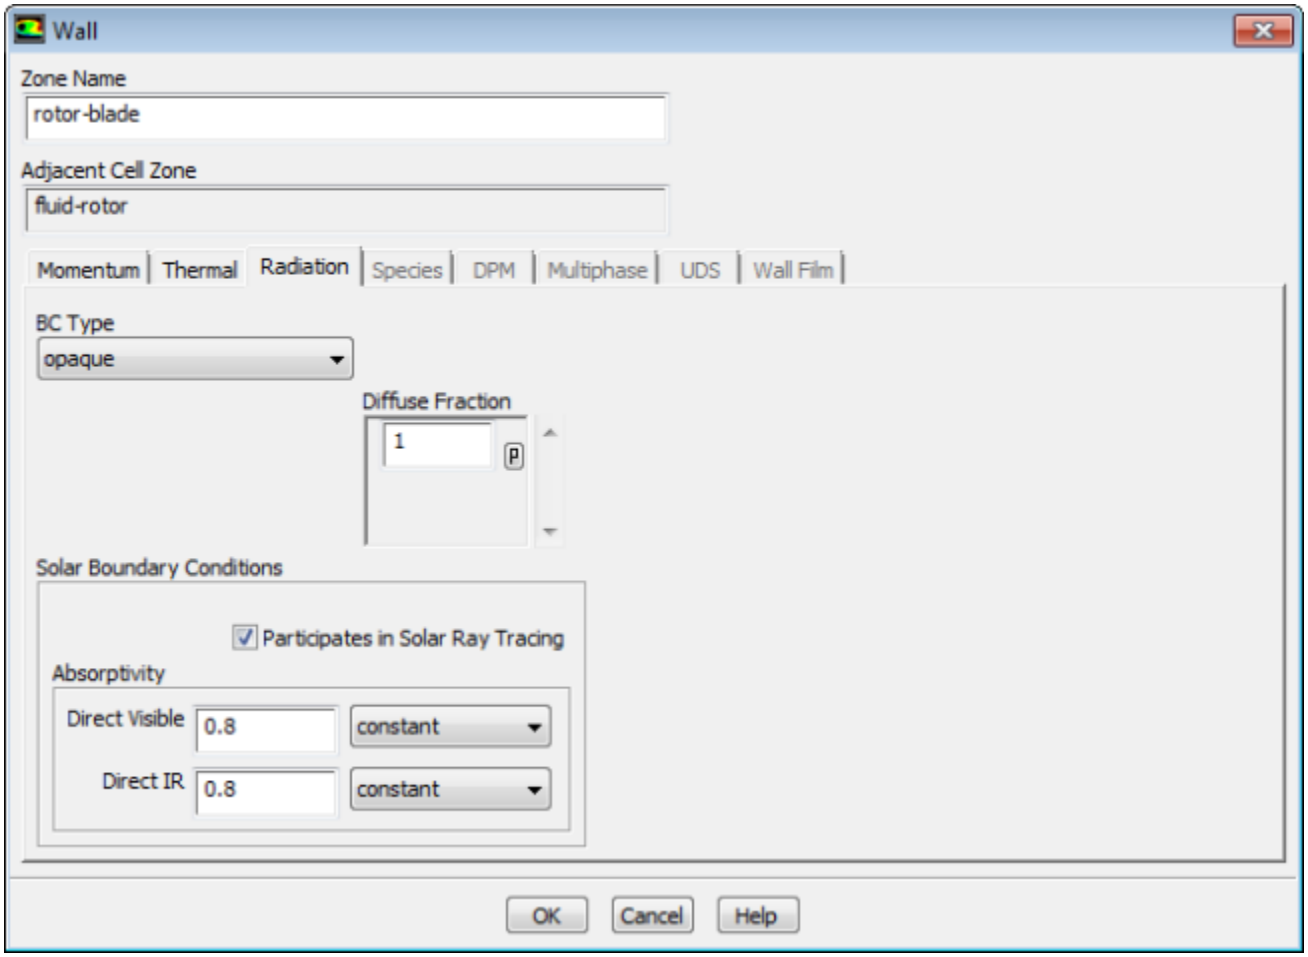
   b. Define the wall as **opaque** or **semi-transparent**. (An opaque wall will not allow any solar radiation to pass through it, while a semi-transparent surface will allow a portion of the solar radiation to pass through it.)

      i. For an opaque wall, select **opaque** from the drop-down list for **BC Type** (Figure 12.37: The Wall Dialog Box (p. 902)). Then enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the **Solar Boundary Conditions** group box and enter constant values for **Direct Visible** and **Direct IR** absorptivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

> **Important**
>
> Absorption in the visible and infrared portions of the spectrum define the surface material for the opaque wall.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

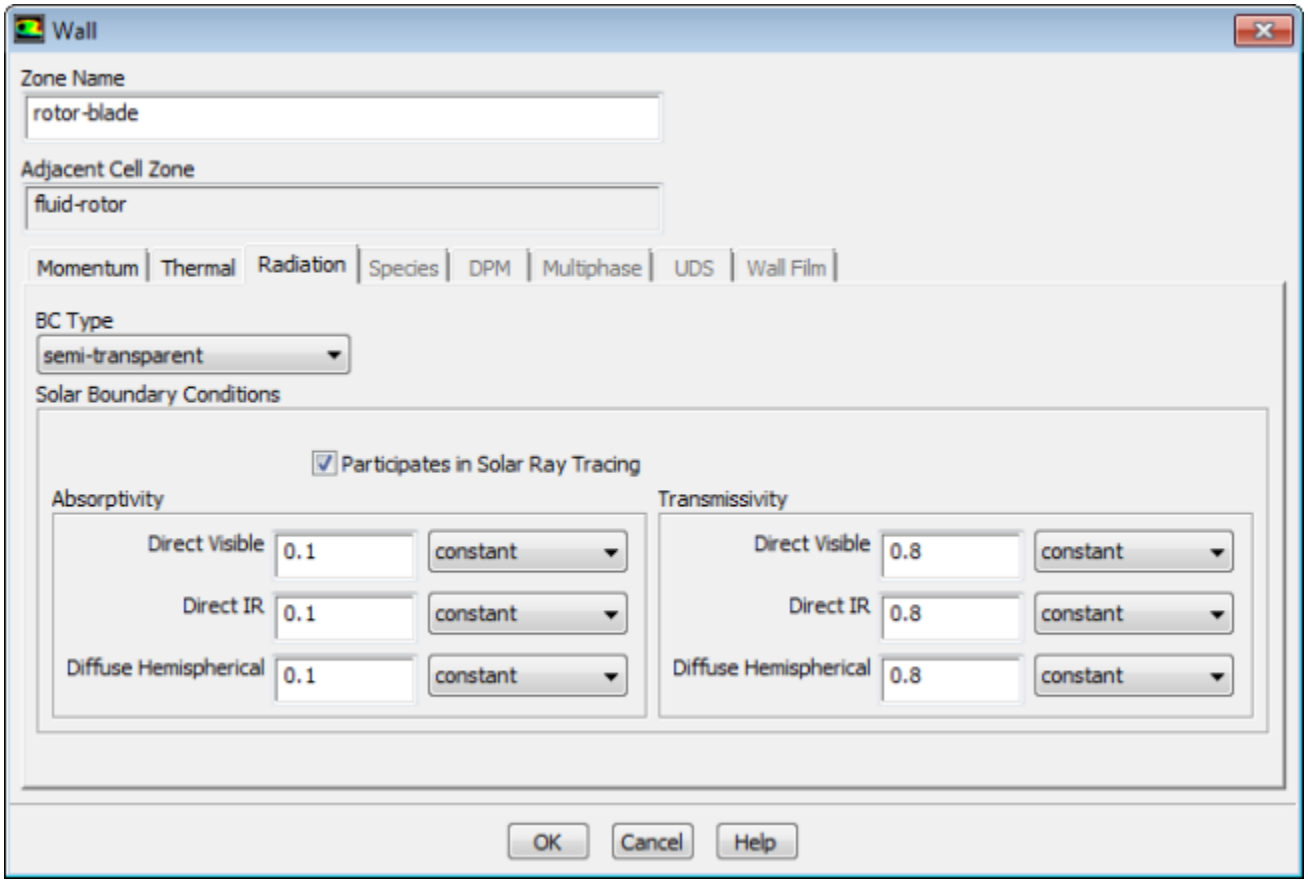
Figure 12.37: The Wall Dialog Box



ii. For a semi-transparent wall, select **semi-transparent** from the drop-down list for **BC Type** (Figure 12.38: The Wall Dialog Box (p. 903)). Then, enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default) in the **Solar Boundary Conditions** group box and enter constant values for **Direct Visible**, **Direct IR**, and **Diffuse Hemispherical** absorptivity and transmissivity. Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.38: The Wall Dialog Box



Important

For semitransparent coupled walls, the solar ray tracing settings are defined on the original wall and not on the shadow wall.

Absorption and transmittance in the visible and infrared portions of the spectrum, as well as the "shading" formulation (**Diffuse Hemispherical**), define the surface material for a semi-transparent wall. These parameters are properties of the glazed unit and should be provided by the glazing manufacturer. The direct components are based on normal incident radiation (ANSYS Fluent adjusts this for the actual angle of incidence). Most manufacturers present this information in a slightly different way so it may be necessary to seek guidance from the supplier. Another useful source of data can be found in the ASHRAE Fundamentals Handbook, chapter on Fenestration.

iii. Click **OK**.

Important

ANSYS Fluent will calculate the reflectivity as the difference between one and the sum of absorptivity and transmissivity:

$$reflectivity = 1 - (absorptivity + transmissivity) \tag{12.21}$$

3. Set the boundary condition for each porous jump boundary zone that you want to include in solar loading. You can define the boundary such that it acts as a semi-transparent surface that will allow a portion of the solar radiation to pass through it, along with fluid flow. In this way you can represent a partial opening (for example, a grate, a grill, or a louver) that is a combination of gaps and (typically) opaque surfaces.

   a. Open the **Porous Jump** boundary condition dialog box (Figure 12.39: The Porous Jump Dialog Box (p. 904)).

   Figure 12.39: The Porous Jump Dialog Box

   b. Define the **Face Permeability**, **Porous Medium Thickness**, **Pressure-Jump Coefficient**, and **Thermal Contact Resistance** as described in User Inputs for the Porous Jump Model (p. 404).

   c. Define the settings in the **Solar Boundary Conditions** group box.

      i. Enable the **Participates in Solar Ray Tracing** option (this option is enabled for all boundary conditions by default). Note that if you deactivate solar ray tracing by disabling the **Participates in Solar Ray Tracing** option, the surface will be ignored and the solar ray will pass through it with no interaction, regardless of the boundary condition type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Absorptivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the absorption of the porous jump.

> **Important**
>
> One reasonable way to estimate the **Direct Visible** and **Direct IR** absorptivity values for a grill, and so on, is to use the product of the obstructed area fraction and the surface absorptivity. For example, if 40% of the grill facial area is obstructed with grill slats, and the slats have a surface absorptivity of 0.7, you could estimate the absorptivity as being 0.28.

iii. Enter constant values (between 0 and 1) for **Direct Visible** and **Direct IR** in the **Transmissivity** group box. These values act as multipliers for the visible and infrared portions of the direct solar radiation spectrum, respectively, to account for the transmissivity of the porous jump.

> **Important**
>
> One reasonable way to estimate the **Direct Visible** and **Direct IR** transmissivity values for a grill, and so on, is to use the open area fraction. For example, if a grill has openings between the slats that amount to 60% of the area, you could estimate the transmissivity as being 0.6.

d. Click **OK**.

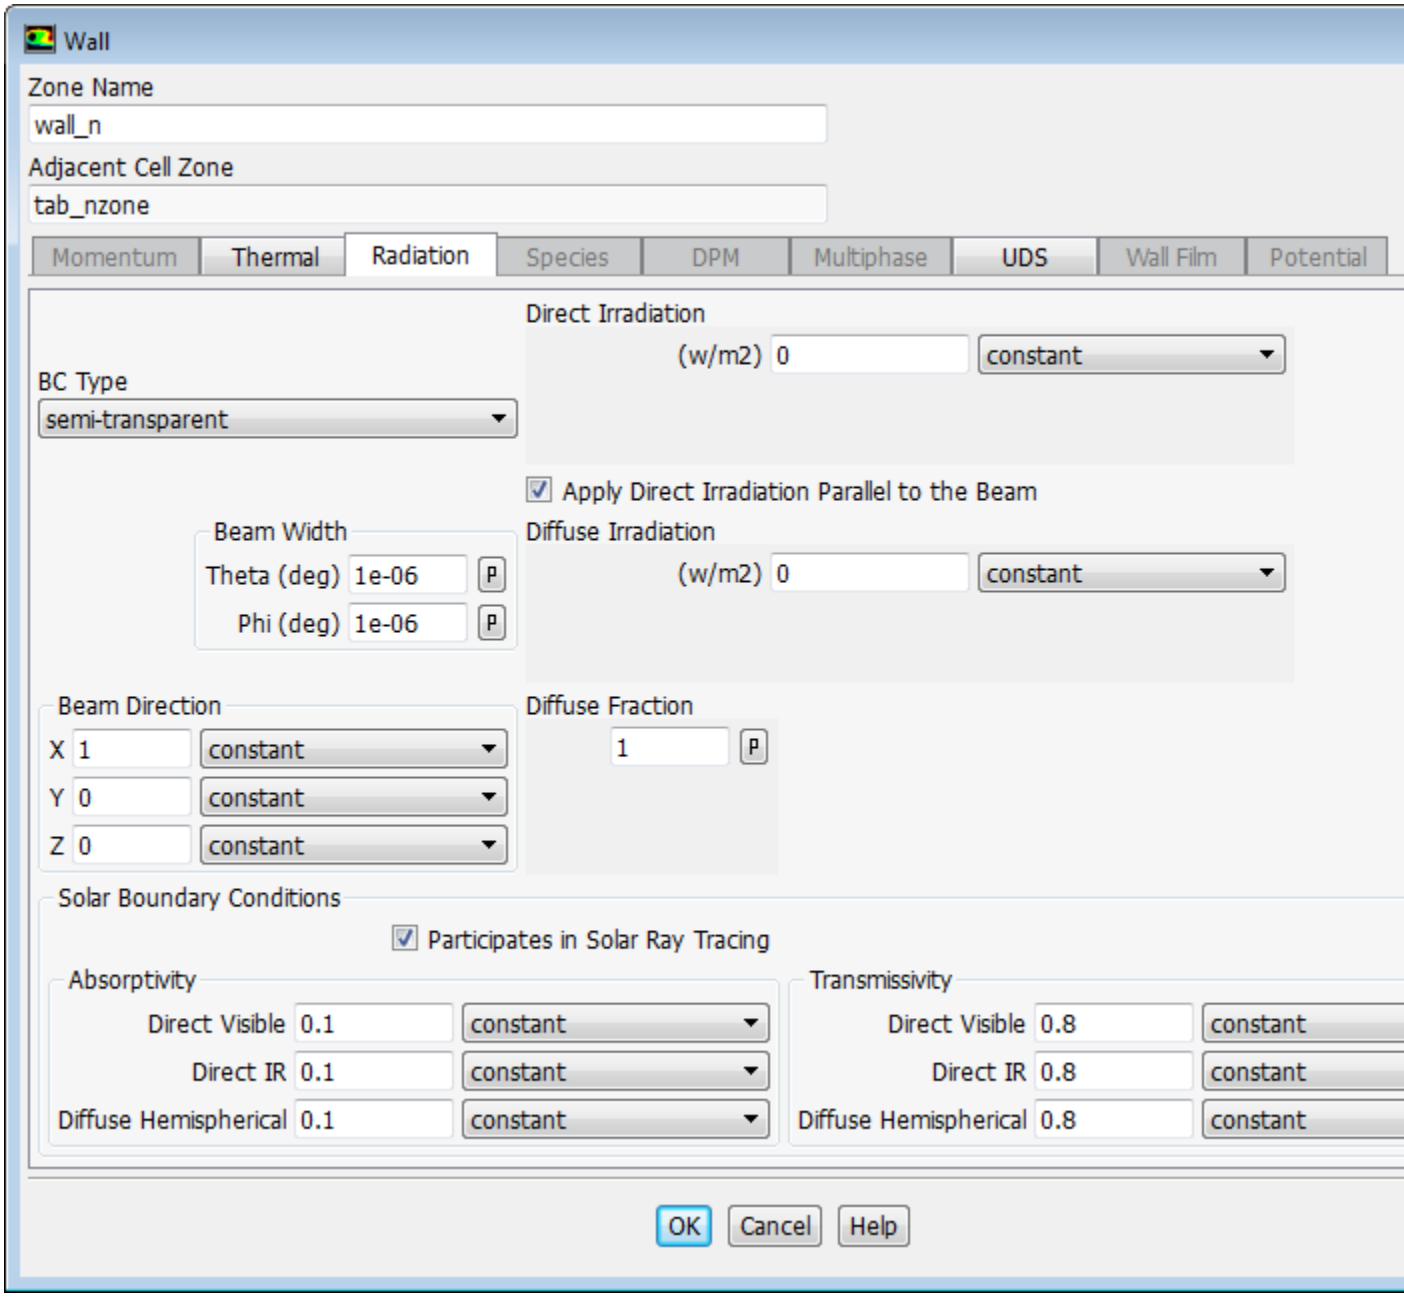
12.3.11.5.5. DO Irradiation

1. For DO irradiation, all boundary conditions are set up as normal for the DO model, except that now you can select semi-transparent boundary surfaces that will provide a source of solar irradiation.

   a. Open a **Wall** boundary condition dialog box and click the **Radiation** tab (Figure 12.40: The Wall Dialog Box (p. 906)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.40: The Wall Dialog Box



b. Select **semi-transparent** from the drop-down list for **BC Type**.

c. Enable the **Use Beam Direction from Solar Load Model Settings** option, under **Solar BC Options**, to have the values for beam direction applied from the **Solar Load Model** settings in the **Radiation** dialog box.

Important

Note that the sign of the beam direction that is needed for the DO model is opposite the sun direction vector that is entered or derived from the solar parameters. The beam direction in the DO model is the direction of external radiation (for example, radiation coming from the sun), while the sun direction vector in the solar load

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

model points to the sun. Incident radiation and sun angle always have an opposite sign since they are quantities that are defined from opposite perspectives.

d. Enable the **Use Direct and Diffuse Irradiation from Solar Load Model Settings** option to have the solar calculator output be applied for direct and diffuse irradiation.

When **Use Direct and Diffuse Irradiation from Solar Load Model Settings** is enabled, the beam width will automatically be set to 0.53 degrees - the angle subtended by the sun.

e. Click **OK**.

12.3.11.5.6. Text Interface-Only Commands

ANSYS Fluent has provided some additional commands for solar load setup that are only available in the text interface. These commands are present in the following sections.

12.3.11.5.6.1. Automatically Saving Solar Ray Tracing Data

It is possible to direct ANSYS Fluent to automatically save solar load data to a generic file that you can examine or use in an external program. This is done by executing the text command `autosave-solar-data` from the text interface.

`define` → `models` → `radiation` → `solar-parameters` → `autosave-solar-data`

1. Enter a value for the autosave solar data file frequency when prompted, in order to specify the frequency (in time steps) at which you want the solar load data written to a file. The default value is zero, which means that no automatic saving is performed.

2. Enter the filename, in quotations.

3. Choose to write file in binary format.

The text interface command for `autosave-solar-data` for a file named `solar` and a frequency of `1` is shown below:

```
/define/models/radiation/solar-parameters> autosave-solar-data
 Autosave Solar Data File Frequency [0] 1
 Enter Filename [""] "solar"
```

12.3.11.5.6.2. Automatically Reading Solar Data

When you are executing a transient simulation in parallel ANSYS Fluent and you want to take solar loading conditions into consideration, you can use the `autoread-solar-data` text command to automatically read the solar load data file you generated during a serial run into parallel ANSYS Fluent. This is done by executing the text command `autoread-solar-data` from the text interface.

`define` → `models` → `radiation` → `solar-parameters` → `autoread-solar-data`

1. Enter a value for the autoread solar data file frequency when prompted, in order to specify the frequency (in time steps) at which you want the solar load data read from the file generated during the serial run. The default value is zero, which means that no automatic reading is performed.

2. Enter the filename, in quotations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The text interface command for autoread-solar-data for a file named solar and a frequency of 1 is shown below:

```
/define/models/radiation/solar-parameters> autoread-solar-data
 Autoread Solar Data File Frequency [0] 1
 Enter Filename [""] "solar"
 Use Binary Format for Reading Data Files [yes]
```

12.3.11.5.6.3. Aligning the Camera Direction With the Position of the Sun

When the solar load model is enabled, you can direct ANSYS Fluent to align the camera direction with the sun position using the text interface command:

define → models → radiation → solar-parameters → sol-camera-pos

This command is useful when you are executing a transient simulation and you want to capture an image of your model with solar load parameters displayed (such as solar heat flux) as the sun position changes with time in order to create an animation. See Postprocessing Solar Load Quantities (p. 909) for details.

12.3.11.5.6.4. Specifying the Scattering Fraction

You can modify the default scattering fraction (1) using the text interface command:

define → models → radiation → solar-parameters → scattering-fraction

The scattering fraction is the amount of direct radiation that has been reflected from opaque surfaces (after entering through the transparent surfaces) that will be considered to remain within the space and be evenly distributed among all surfaces. The value is between 0 and 1.

The text interface command for specifying a scattering-fraction of 0.5 is shown below:

```
/define/models/radiation/solar-parameters> scattering-fraction
 Scattering Fraction [1] .5
```

12.3.11.5.6.5. Applying the Solar Load on Adjacent Fluid Cells

You can direct ANSYS Fluent to apply the solar load that is computed from the solar ray tracing algorithm to adjacent fluid cells by issuing the following command at the text interface:

define → models → radiation → solar-parameters → sol-adjacent-fluidcells

The text interface command is shown below:

```
/define/models/radiation/solar-parameters> sol-adjacent-fluidcells
 Apply Solar Load on adjacent Fluid Cells? [no] y
```

This command allows you to apply solar loads to adjacent fluid cells only, even if solid or shell conduction zones are present. By applying the solar load on adjacent fluid cells, you are overruling the default order of the adjacent cell assignment in ANSYS Fluent which is shell, solid, fluid.

12.3.11.5.6.6. Specifying Quad Tree Refinement Factor

You can modify the default value (7) for the maximum quad tree refinement factor in the solar ray tracing algorithm using the text command:

define → models → radiation → solar-parameters → quad-tree-parameters

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The text interface command is shown below, when a new maximum refinement value of 10 is specified:

```
/define/models/radiation/solar-parameters> quad-tree-parameters
 Maximum Quad-Tree Refinement [7] 10
```

12.3.11.5.6.7. Specifying Ground Reflectivity

You can modify the default value (0.2) for the ground reflectivity using the text command:

`define` → `models` → `radiation` → `solar-parameters` → `ground-reflectivity`

Ground reflectivity ρ_g (Equation 12.19 (p. 893)) includes the contribution of reflected solar radiation from ground surfaces. It is treated as part of the total diffuse solar irradiation when the solar calculator is used in conjunction with the `Diffuse Solar Irradiation` illumination parameter. The default value is 0.2.

```
/define/models/radiation/solar-parameters> ground-reflectivity
 Ground Reflectivity [0.2] 0.5
```

12.3.11.5.6.8. Additional Text Interface Commands

Some solar load commands that are available in the graphical user interface are also made available in the text interface. For example, you can turn the solar load model on using the text command:

`define` → `models` → `radiation` → `solar?`

You can also enter the solar calculator parameters in the text interface by executing the command:

`define` → `models` → `radiation` → `solar-calculator`

Once invoked, you will be prompted to enter the solar calculator input parameters.

To set the illumination parameters, select this option from the `solar-parameters` menu:

`define` → `models` → `radiation` → `solar-parameters` → `illumination-parameters`

And finally, you can direct ANSYS Fluent to compute the solar load on demand, by issuing the text command:

`define` → `models` → `radiation` → `solar-parameters` → `sol-on-demand`

When the command is initiated, the solar data are written to the console.

12.3.11.6. Postprocessing Solar Load Quantities

The following solar load quantities can be used to visualize the illuminated areas and shadows created by solar radiation.

- solar heat flux (that is, sum of visible and IR absorbed solar flux on opaque walls)
- absorbed visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- reflected visible and IR solar flux (semi-transparent walls and porous jump boundaries only)
- transmitted visible and IR solar flux (semi-transparent walls and porous jump boundaries only)

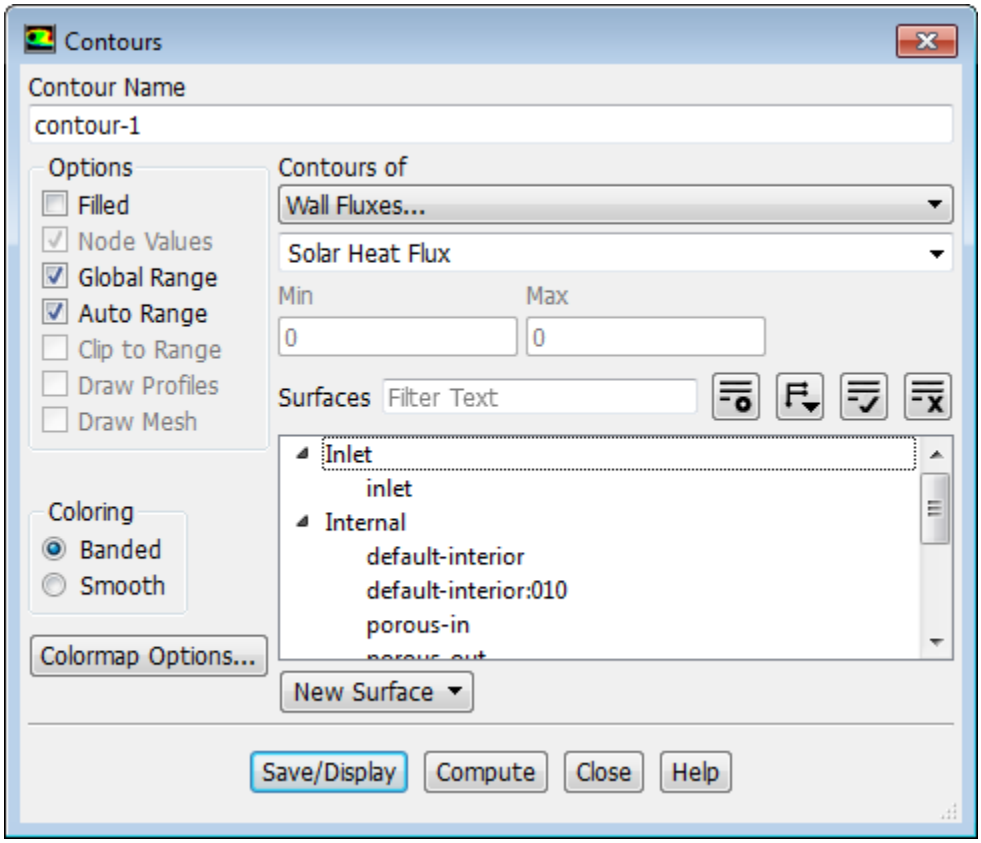
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

These quantities are available for postprocessing of solar loading at wall boundaries and can be displayed as contours of **Wall Fluxes** in the **Contours** dialog box. For steady-state simulations, the solar flux data is computed at solution initialization and is available for postprocessing. You can also compute the solar load at any time during your ANSYS Fluent session, after you have set up the model and applied boundary conditions. To compute the solar load on demand, you can issue the `sol-on-demand` command in the text interface (see Additional Text Interface Commands (p. 909) for details).

Solar heat flux, for example, can be displayed for surfaces using the **Contours** dialog box. A sample dialog box is shown below (Figure 12.41: The Contours Dialog Box (p. 910)).

Results → Graphics → Contours New...

Figure 12.41: The Contours Dialog Box



12.3.11.6.1. Solar Load Animation at Different Sun Positions

The solar camera alignment command is useful when you want to take timed pictures of solar loading effects of your model during transient simulations, and later create animations of the image files using an external program. Follow the procedure below.

1. Read (or set up) your transient case file in ANSYS Fluent.

2. Set up the automatic execution of solution commands in the **Execute Commands** dialog box that will: 1) display solar load parameter graphics, 2) re-position the solar camera such that the view is aligned with the instantaneous sun direction, and 3) generate a picture image file (`.tiff`) during the solution process in the **Execute Commands** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → **Calculation Activities** → **Execute Commands** **Edit...**

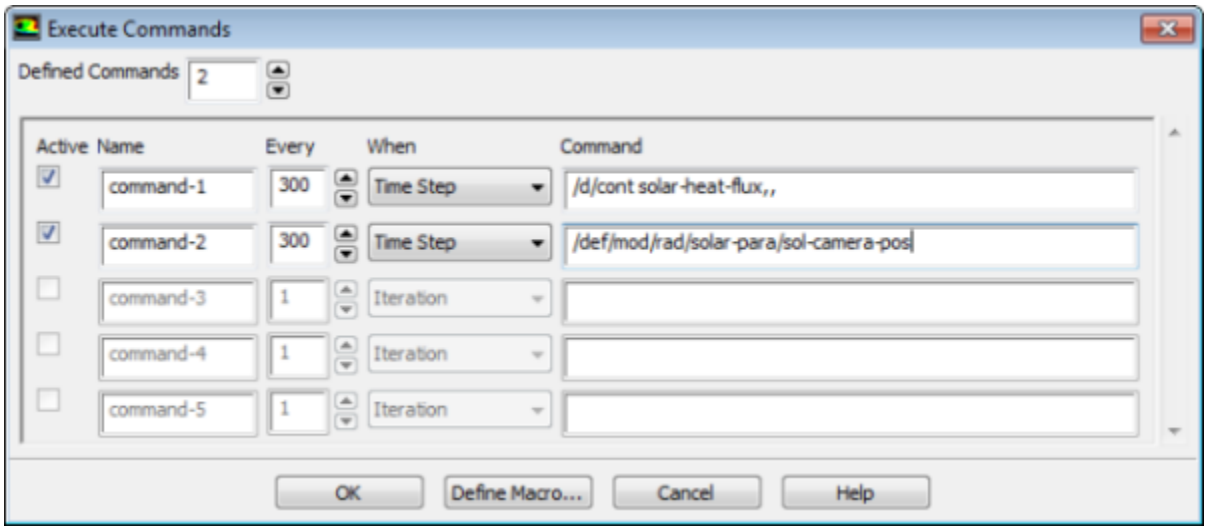
3. Initialize and run the solution.

4. Animate the `.tiff` files using an external animation tool.

The following commands entered in the **Execute Commands** dialog box will direct ANSYS Fluent to display contours of solar heat flux, align the camera with the current direction of the sun, and then generate a picture image file (`.tiff`) of the solar heat flux contour every 300 time steps during the unsteady simulation. See Figure 12.42: The Execute Commands Dialog Box (p. 911).

```
/di/cont solar-heat-flux ,,
/def/mod/rad/solar-para/sol-camera-pos
/di/hc "flux-%t.tiff"
```

Figure 12.42: The Execute Commands Dialog Box



12.3.11.6.2. Reporting and Displaying Solar Load Quantities

ANSYS Fluent provides some additional solar load variables that you can use for postprocessing when your model includes solar ray tracing. You can generate graphical plots or alphanumeric reports of the following variables:

In the **Wall Fluxes...** category:

- **Solar Heat Flux**
- **Transmitted Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Transmitted IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Reflected IR Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed Visible Solar Flux** (semi-transparent walls and porous jump boundaries)
- **Absorbed IR Solar Flux** (semi-transparent walls and porous jump boundaries)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Field Function Definitions (p. 1931) for their definitions.

12.4. Modeling Periodic Heat Transfer

ANSYS Fluent is able to predict heat transfer in periodically repeating geometries, such as compact heat exchangers, by including only a single periodic module for analysis.

This section discusses streamwise-periodic heat transfer. The treatment of streamwise-periodic flows is discussed in Periodic Flows (p. 582), and a description of no-pressure-drop periodic flow is provided in Periodic Boundary Conditions (p. 386).

Information about streamwise-periodic heat transfer is presented in the following sections:

12.4.1. Overview and Limitations
12.4.2. Theory
12.4.3. Using Periodic Heat Transfer
12.4.4. Solution Strategies for Periodic Heat Transfer
12.4.5. Monitoring Convergence
12.4.6. Postprocessing for Periodic Heat Transfer

12.4.1. Overview and Limitations

The following sections contain information about periodic heat transfer:

12.4.1.1. Overview
12.4.1.2. Constraints for Periodic Heat Transfer Predictions

12.4.1.1. Overview

As discussed in Overview and Limitations (p. 582), streamwise-periodic flow conditions exist when the flow pattern repeats over some length L, with a constant pressure drop across each repeating module along the streamwise direction.

Periodic thermal conditions may be established when the thermal boundary conditions are of the constant wall temperature or wall heat flux type. In such problems, the temperature field (when scaled in an appropriate manner) is periodically fully developed [81] (p. 2891). As for periodic flows, such problems can be analyzed by restricting the numerical model to a single module or periodic length.

12.4.1.2. Constraints for Periodic Heat Transfer Predictions

In addition to the constraints for streamwise-periodic flow discussed in Limitations for Modeling Streamwise-Periodic Flow (p. 583), the following constraints must be met when periodic heat transfer is to be considered:

- The pressure-based solver must be used.
- The thermal boundary conditions must be of the specified heat flux or constant wall temperature type. Furthermore, in a given problem, these thermal boundary types cannot be combined: all boundaries must be either constant temperature or specified heat flux. You can, however, include constant-temperature walls and zero-heat-flux walls in the same problem. For the constant-temperature case, all walls must be at the same temperature (profiles are not allowed) or zero heat flux. For the heat flux case, profiles and/or different values of heat flux may be specified at different walls.
- When constant-temperature wall boundaries are used, you cannot include viscous heating effects or any volumetric heat sources.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In cases that involve solid regions, the regions cannot straddle the periodic plane.
- The thermodynamic and transport properties of the fluid (heat capacity, thermal conductivity, viscosity, and density) cannot be functions of temperature. (You cannot, therefore, model reacting flows.) Transport properties may, however, vary spatially in a periodic manner, and this allows you to model periodic turbulent flows in which the effective turbulent transport properties (effective conductivity, effective viscosity) vary with the (periodic) turbulence field.

Theory (p. 913) and Using Periodic Heat Transfer (p. 914) provide more detailed descriptions of the input requirements for periodic heat transfer.

12.4.2. Theory

Streamwise-periodic flow with heat transfer from constant-temperature walls is one of two classes of periodic heat transfer that can be modeled by ANSYS Fluent. A periodic fully developed temperature field can also be obtained when heat flux conditions are specified. In such cases, the temperature change between periodic boundaries becomes constant and can be related to the net heat addition from the boundaries as described in this section.

Important

Periodic heat transfer can be modeled only if you are using the pressure-based solver.

12.4.2.1. Definition of the Periodic Temperature for Constant- Temperature Wall Conditions

For the case of constant wall temperature, as the fluid flows through the periodic domain, its temperature approaches that of the wall boundaries. However, the temperature can be scaled in such a way that it behaves in a periodic manner. A suitable scaling of the temperature for periodic flows with constant-temperature walls is [81] (p. 2891)

$$\theta = \frac{T(\vec{r}) - T_{wall}}{T_{bulk,inlet} - T_{wall}} \tag{12.22}$$

The bulk temperature, $T_{bulk,inlet}$, is defined by

$$T_{bulk,inlet} = \frac{\int_A T \left| \rho \vec{v} \cdot d\vec{A} \right|}{\int_A \left| \rho \vec{v} \cdot d\vec{A} \right|} \tag{12.23}$$

where the integral is taken over the inlet periodic boundary (A). It is the scaled temperature, θ, which obeys a periodic condition across the domain of length L.

12.4.2.2. Definition of the Periodic Temperature Change σ for Specified Heat Flux Conditions

When periodic heat transfer with heat flux conditions is considered, the form of the unscaled temperature field becomes analogous to that of the pressure field in a periodic flow:

$$\frac{T(\vec{r}+\vec{L}) - T(\vec{r})}{L} = \frac{T(\vec{r}+2\vec{L}) - T(\vec{r}+\vec{L})}{L} = \sigma. \tag{12.24}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where $\vec{L}$ is the periodic length vector of the domain. This temperature gradient, σ, can be written in terms of the total heat addition within the domain, Q, as

$$\sigma = \frac{Q}{\dot{m} c_p L} = \frac{T_{bulk,exit} - T_{bulk,inlet}}{L} \tag{12.25}$$

where $\dot{m}$ is the specified or calculated mass flow rate.

12.4.3. Using Periodic Heat Transfer

A typical calculation involving both streamwise-periodic flow and periodic heat transfer is performed in two parts. First, the periodic velocity field is calculated (to convergence) without consideration of the temperature field. Next, the velocity field is frozen and the resulting temperature field is calculated. These periodic flow calculations are accomplished using the following procedure:

1. Set up a mesh with translationally periodic boundary conditions.
2. Specify constant thermodynamic and molecular transport properties.
3. Specify either the periodic pressure gradient or the net mass flow rate through the periodic boundaries.
4. Compute the periodic flow field, solving momentum, continuity, and (optionally) turbulence equations.
5. Specify the thermal boundary conditions at walls as either heat flux or constant temperature.
6. Define an inlet bulk temperature.
7. Solve the energy equation (only) to predict the periodic temperature field.

In order to model the periodic heat transfer, you will need to set up your periodic model in the manner described in User Inputs for the Pressure-Based Solver (p. 584) for periodic flow models with the pressure-based solver, noting the restrictions discussed in Limitations for Modeling Streamwise-Periodic Flow (p. 583) and Constraints for Periodic Heat Transfer Predictions (p. 912). In addition, you will need to provide the following inputs related to the heat transfer model:

1. Enable the solution of the energy equation by right-clicking **Energy** in the tree (under **Setup/Models**) and clicking **On** in the menu that opens (Figure 12.1: Enabling the Energy Equation (p. 826)).

   Setup → **Models** → **Energy** → **On**

2. Define the thermal boundary conditions according to one of the following procedures. The boundary condition dialog boxes can be opened by right-clicking the boundary name in the tree (under **Setup/Boundary Conditions**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Boundary Conditions** task page:

   Setup → **Boundary Conditions**

   - If you are modeling periodic heat transfer with specified-temperature boundary conditions, set the wall temperature T_{wall} for all wall boundaries in their respective **Wall** dialog box. Note that all wall boundaries must be assigned the same temperature and that the entire domain (except the periodic boundaries) must be "enclosed" by this fixed-temperature condition, or by symmetry or adiabatic (q=0) boundaries.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you are modeling periodic heat transfer with specified-heat-flux boundary conditions, set the wall heat flux in the **Wall** dialog box for each wall boundary. You can define different values of heat flux on different wall boundaries, but you should have no other types of thermal boundary conditions active in the domain.

3. Define solid regions, if appropriate, according to one of the following procedures. The cell zones can be defined by right-clicking the zone name in the tree (under **Setup/Cell Zone Conditions**), or using the **Cell Zone Conditions** task page:

   Setup → **Cell Zone Conditions**

   - If you are modeling periodic heat transfer with specified-temperature conditions, conducting solid regions can be used within the domain, provided that on the perimeter of the domain they are enclosed by the fixed-temperature condition. Heat generation within the solid regions is not allowed when you are solving periodic heat transfer with fixed-temperature conditions.

   - If you are modeling periodic heat transfer with specified-heat-flux conditions, you can define conducting solid regions at any location within the domain, including volumetric heat addition within the solid, if desired.

4. Set constant material properties (density, heat capacity, viscosity, thermal conductivity), *not* temperature-dependent properties, using the **Create/Edit Materials** dialog box. This dialog box can be opened by right-clicking the material name in the tree (under **Setup/Materials**) and clicking **Edit...** in the menu that opens; alternatively, you can open them from the **Materials** task page:

   Setup → **Materials**

5. Specify the **Upstream Bulk Temperature** in the **Periodic Conditions** dialog box, which can be opened from **Boundary Conditions** task page:

   Setup → **Boundary Conditions** → **Periodic Conditions...**

   Important

   If you are modeling periodic heat transfer with specified-temperature conditions, the bulk temperature should not be equal to the wall temperature, since this will give you the trivial solution of constant temperature everywhere.

6. Set the solution parameters as described in Solution Strategies for Periodic Heat Transfer (p. 915).

7. Run the solution and monitor the convergence as described in Monitoring Convergence (p. 916).

8. Postprocess the results as described in Postprocessing for Periodic Heat Transfer (p. 916).

12.4.4. Solution Strategies for Periodic Heat Transfer

After completing the inputs described in Using Periodic Heat Transfer (p. 914), you can solve the flow and heat transfer problem to convergence. The most efficient approach to the solution, however, is a sequential one in which the periodic flow is first solved without heat transfer and then the heat transfer is solved leaving the flow field unaltered. This sequential approach is accomplished as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Disable solution of the energy equation in the **Equations** dialog box; this dialog box is accessed by right-clicking **Solution Controls** in the tree (under **Solution**) and clicking **Equations...** in the menu that opens.

   Solution → **Controls** **Equations...**

2. Solve the remaining equations (continuity, momentum, and, optionally, turbulence parameters) to convergence to obtain the periodic flow field.

   Important

   When you initialize the flow field before beginning the calculation, use the mean value between the inlet bulk temperature and the wall temperature for the initialization of the temperature field.

3. Return to the **Equations** dialog box and turn off solution of the flow equations and turn on the energy solution.

4. Solve the energy equation to convergence to obtain the periodic temperature field of interest.

While you can solve your periodic flow and heat transfer problems by considering both the flow and heat transfer simultaneously, you will find that the procedure outlined above is more efficient.

12.4.5. Monitoring Convergence

If you are modeling periodic heat transfer with specified-temperature conditions, you can monitor the value of the bulk temperature ratio

$$\theta = \frac{T_{wall} - T_{bulk,inlet}}{T_{wall} - T_{bulk,exit}} \tag{12.26}$$

during the calculation by creating a report plot that includes bulk temperature ratio (**per-bulk-temp-ratio**), to ensure that you reach a converged solution. See Monitoring Statistics (p. 1633) for additional information.

12.4.6. Postprocessing for Periodic Heat Transfer

The actual temperature field predicted by ANSYS Fluent in periodic models will not be periodic, and viewing the temperature results during postprocessing will display this actual temperature field ($T(\vec{r})$ of Equation 12.22 (p. 913)). The displayed temperature may exhibit values outside the range defined by the inlet bulk temperature and the wall temperature. This is permissible since the actual temperature profile at the inlet periodic face will have temperatures that are higher or lower than the inlet bulk temperature.

Static Temperature is found in the **Temperature...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

Figure 12.43: Temperature Field in a 2D Heat Exchanger Geometry With Fixed Temperature Boundary Conditions (p. 917) shows the temperature field in a periodic heat exchanger geometry.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 12.43: Temperature Field in a 2D Heat Exchanger Geometry With Fixed Temperature Boundary Conditions

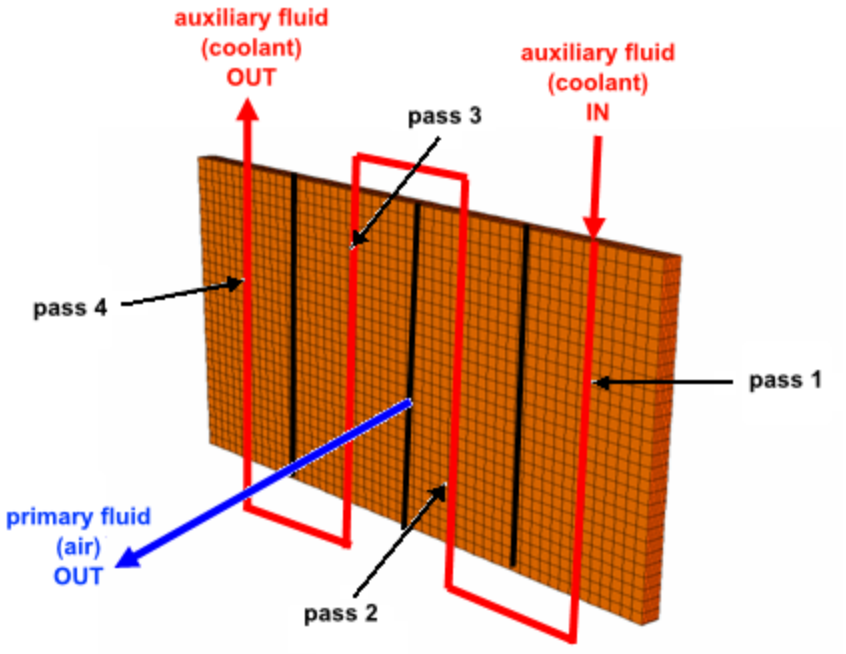
Chapter 13: Modeling Heat Exchangers

Many engineering systems, including power plants, climate control, and engine cooling systems typically contain tubular heat exchangers. However, for most engineering problems, it is impractical to model individual fins and tubes of a heat exchanger core. In principle, heat exchanger cores introduce a pressure drop to the primary fluid stream and transfer heat from or to a second fluid (for example, a coolant), referred to here as the auxiliary fluid.

ANSYS Fluent provides two distinct methods of modeling a heat exchanger: the dual cell model and the macro model. These models can be used to compute the auxiliary fluid inlet temperature for a fixed heat rejection or the total heat rejection for a fixed auxiliary fluid inlet temperature. The dual cell model allows the solution of the passes of the auxiliary flow on a separate mesh, that is, other than the primary fluid mesh (see Figure 13.1: An Example of a Four-Pass Heat Exchanger (p. 919)), unlike the macro model, where the auxiliary flow passes are modeled as 1D flow.

Figure 13.1: An Example of a Four-Pass Heat Exchanger



Important

Note that the heat exchanger models are not appropriate for modeling a cold-only flow; in such a case, you should instead use the porous media model, as described in Porous Media Conditions (p. 261).

For theoretical information about the various heat exchanger models, refer to Heat Exchangers in the Theory Guide.

The following sections contain information about the heat exchanger models:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13.1. Choosing a Heat Exchanger Model
13.2. The Dual Cell Model
13.3. The Macro Heat Exchanger Models
13.4. Postprocessing for the Heat Exchanger Model
13.5. Useful Reporting TUI Commands

13.1. Choosing a Heat Exchanger Model

ANSYS Fluent provides various options for modeling heat exchangers, each with their own features and limitations. The following instructions can help you determine which option/combination of options is the most appropriate for your problem.

1. Decide whether you want to use the dual cell model or the macro model.

   a. The dual cell model provides the greatest flexibility with regard to the shape of the heat exchanger core and the nature of the mesh, and allows the auxiliary fluid to be highly non-uniform as it enters the core (for example, due to passing through arbitrary shaped inlet tanks). However, the dual cell model may need to be discounted as an option because of the following limitations:

      - If the heat exchanger performance data that you have is in the form of a velocity vs. effectiveness curve, the dual cell model cannot be used.
      - The dual cell model does not allow you to model phase change in the auxiliary fluid.

      If the previous limitations are not relevant for your problem, you can proceed directly to using the dual cell model, as described in Using the Dual Cell Heat Exchanger Model (p. 922).

   b. While the macro model has more restrictions than the dual cell model, it is quite suitable for a thin 3D heat exchanger core with a rectangular cross-section, where the pass-to-pass plane is perpendicular to the primary flow direction, the auxiliary flow is uniform (so it can be treated as a 1D flow), and the mesh is uniform and structured. To verify that your problem can tolerate the limitations of the macro model, see Restrictions (p. 931).

2. If you chose to use the macro model in the previous step, you must decide whether you want to use the grouped or ungrouped version of this model. If you want to define a single heat exchanger using multiple fluid zones, or if you would like to connect the fluid flow path among multiple heat exchangers, you should use the grouped version, as described in Using the Grouped Macro Heat Exchanger Model (p. 943). Otherwise, you can use the ungrouped version, as described in Using the Ungrouped Macro Heat Exchanger Model (p. 932).

3. If you chose to use the macro model in the step 1., you must decide whether you want to model the heat transfer using the number-of-transfer-units (NTU) method or the simple effectiveness method. This decision largely rests on the kind of experimental data that you have: the NTU method requires that you provide the various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values; the simple effectiveness method requires that you provide the data points for a curve that defines how the effectiveness (that is, the ratio of actual rate of heat transfer between the primary and auxiliary fluids to the maximum possible rate of heat transfer)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

varies with the fluid velocity. Additionally, you should consider the differences between the two heat transfer models outlined in Table 13.1: NTU Model Vs. Simple Effectiveness Model (p. 921).

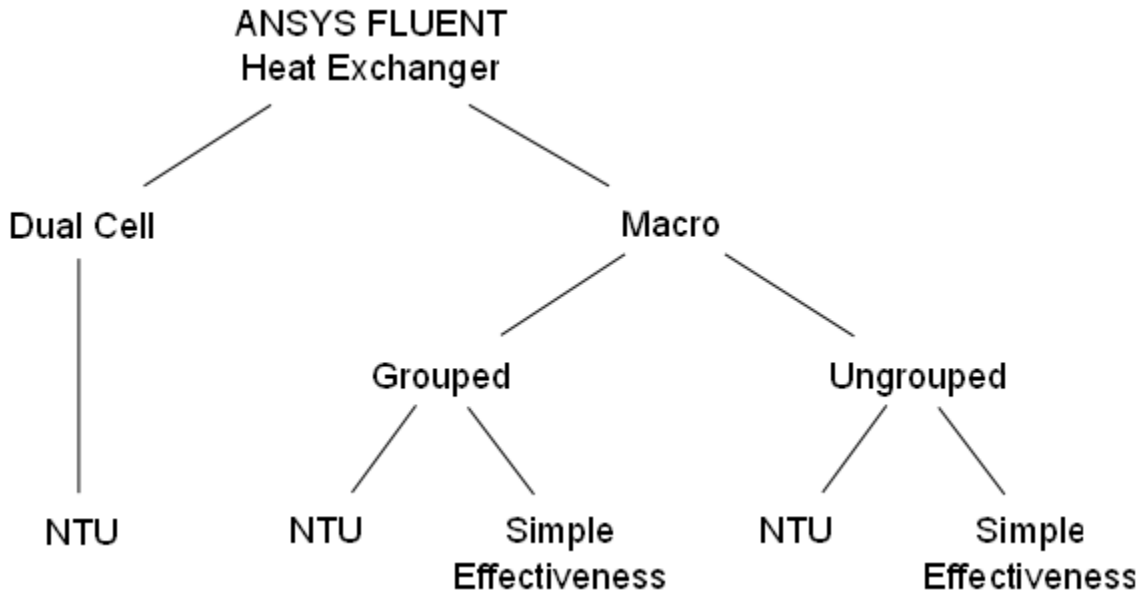
Table 13.1: NTU Model Vs. Simple Effectiveness Model

	NTU Model	Simple Effectiveness Model
How many phases are allowed in the auxiliary flow?	single phase only	single phase and two phase
Can you model primary fluid-side reverse flow?	Yes	No
Can the primary fluid have a variable density?	Yes	No
Must the primary fluid heat capacity be less than the auxiliary fluid heat capacity?	No	Yes

You will specify whether you want the NTU or simple effectiveness model in the **Model Data** tab of either the **Ungrouped Macro Heat Exchanger** dialog box or the **Heat Exchanger Group** dialog box, depending on whether you opted for the ungrouped or grouped version of the macro model, respectively.

An overview of the options available to you when modeling heat exchangers is shown in Figure 13.2: Heat Exchanger Modeling Options (p. 921).

Figure 13.2: Heat Exchanger Modeling Options



13.2. The Dual Cell Model

The dual cell heat exchanger model allows the solution of both the primary and auxiliary flow on separate co-located meshes and couples the two flows only through heat transfer at the heat exchanger core.

For theoretical information about this model, refer to The Dual Cell Model in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13.2.1. Restrictions

The following restrictions exist for the dual cell heat exchanger models:

- The simple effectiveness model is not available.
- The heat exchanger performance data must be in the form of heat transfer rates or number of transfer units (NTU) for auxiliary / primary fluid flow rate combinations, rather than a velocity vs. effectiveness curve.
- In the case of a heat exchanger in which the primary and auxiliary meshes are not identical, heat transfer may be non-conservative (that is, the heat lost by the hot fluid may not equal the heat gained by the cold fluid). To minimize the difference in heat transfer, the topology and size of the primary and auxiliary cells should be as similar as possible, with the ideal being one-to-one cell conductivity. Note that you can make the meshes identical by copying a zone via the `mesh/modify-zones/copy-move-cell-zone` text command.

13.2.2. Using the Dual Cell Heat Exchanger Model

The steps for setting up the dual cell heat exchanger model is as follows:

1. Read the mesh file.

   a. If the mesh file does not already contain overlapping heat exchanger cores for primary and auxiliary fluids, then you must create a duplicate of the zone that represents the core using the following text command:

      `mesh` → `modify-zones` → `copy-move-cell-zone`

      See Copying Cell Zones (p. 222) for details on copying meshes.

   b. Make sure that the auxiliary fluid mesh is divided into separate zones, one for each pass.

      Setting Up Domain → **Zones** → **Separate** → **Cells...**

      See Separating Cell Zones (p. 210) for details on separating meshes.

   c. Make sure that the inlet and outlet for the heat exchanger are two separate zones.

2. Enable the calculation of energy in the **Energy** dialog box.

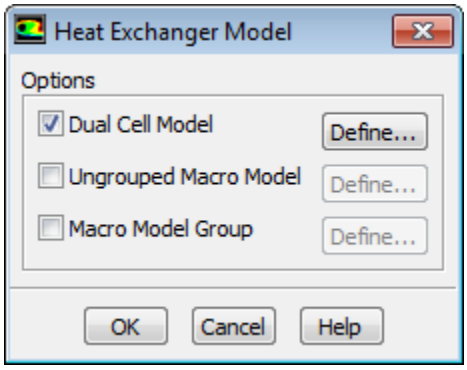
   Setup → **Models** → **Energy** **ON**

3. Enable the **Dual Cell Model** in the **Heat Exchanger Model** dialog box and click **Define...** (Figure 13.3: The Heat Exchanger Model Dialog Box (p. 923)).

   Setup → **Models** → **Heat Exchanger** **Edit...**

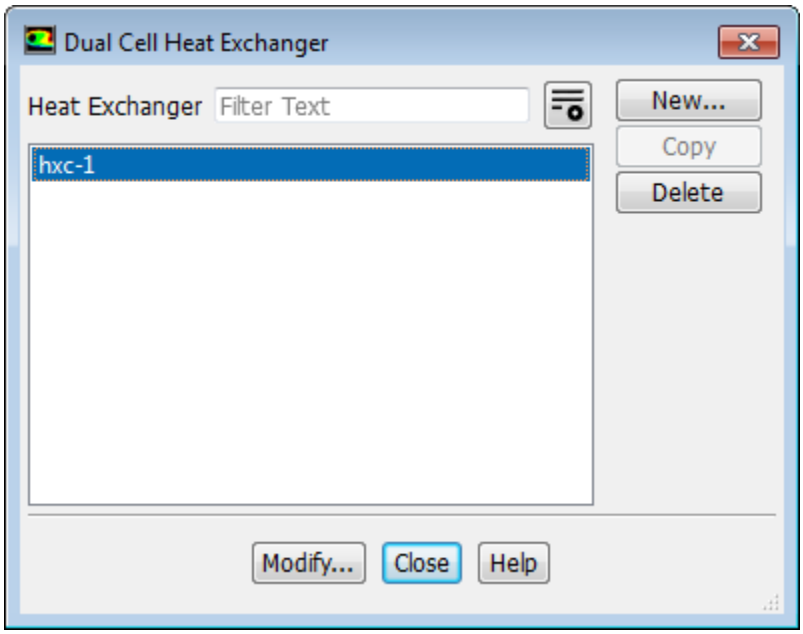
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.3: The Heat Exchanger Model Dialog Box



4. Specify the inputs to the dual cell heat exchanger model, using the **Dual Cell Heat Exchanger** dialog box (Figure 13.4: The Dual Cell Heat Exchanger Dialog Box (p. 923)).

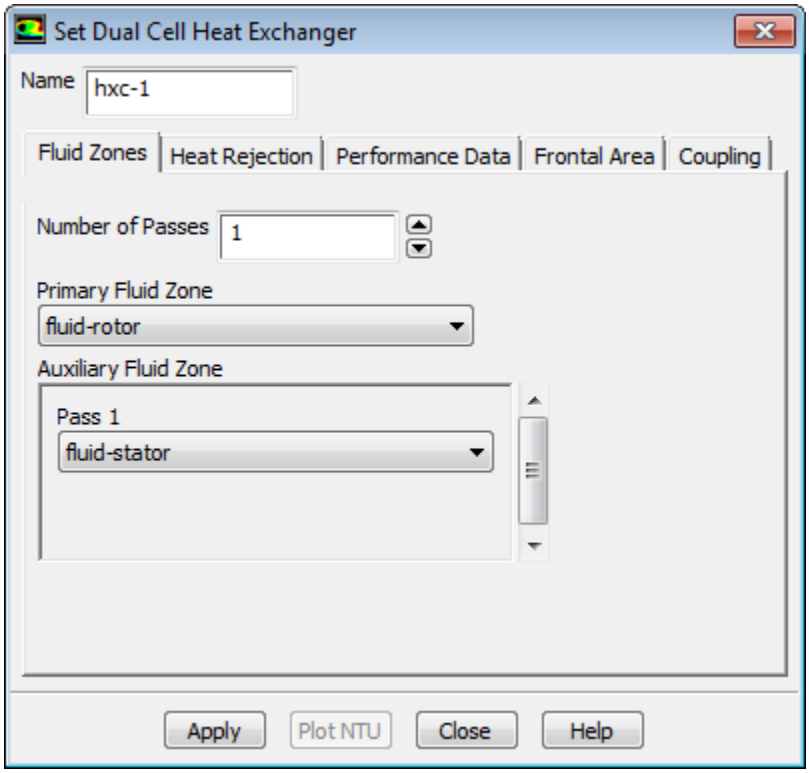
Figure 13.4: The Dual Cell Heat Exchanger Dialog Box



5. Click **New...** to define the heat exchanger. The **Set Dual Cell Heat Exchanger** dialog box will appear (Figure 13.5: The Set Dual Cell Heat Exchanger Dialog Box (p. 924)), where you will define the heat exchanger parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.5: The Set Dual Cell Heat Exchanger Dialog Box



a. Enter the heat exchanger **Name** or keep the default name. The suffix `-1` is incremented automatically on defining more than one heat exchanger.

b. In the **Fluid Zones** tab (Figure 13.5: The Set Dual Cell Heat Exchanger Dialog Box (p. 924))

   i. Specify the **Number of Passes** of your heat exchanger.

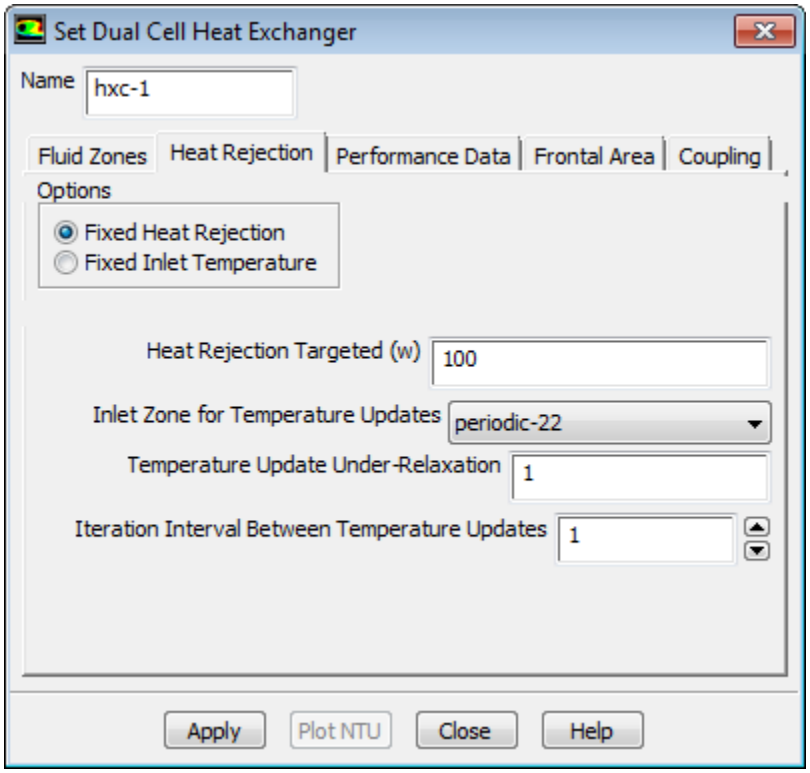
   ii. Select the appropriate **Primary** and **Auxiliary Fluid Zone**, representing the heat exchanger core.

> **Important**
>
> The selected zones must be overlapping in physical space.

c. Click the **Heat Rejection** tab (Figure 13.6: The Heat Rejection Tab (p. 925)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.6: The Heat Rejection Tab



i. If you select **Fixed Heat Rejection**, set the inputs for the following:

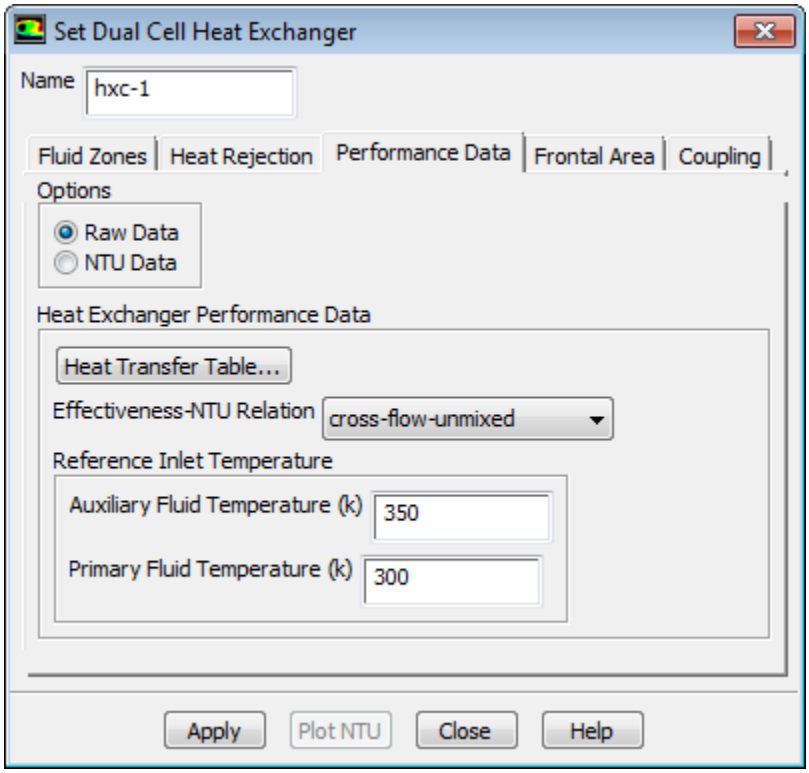
- **Heat Rejection Targeted** which is the heat rejection desired from the heat exchanger.
- **Inlet Zone for Temperature Updates** allows ANSYS Fluent to change the temperature of the specified inlet zone in order to match the targeted heat rejection.
- **Temperature Update Under-Relaxation** is a factor that controls convergence.
- **Iteration Interval Between Temperature Updates** is used to control divergence.

ii. Select **Fixed Inlet Temperature** if the output desired is total heat rejection.

d. Click the **Performance Data** tab (Figure 13.7: The Performance Data Tab (p. 926)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.7: The Performance Data Tab



You must decide whether you will select **Raw Data** or **NTU Data** from the **Options** list. Using the **Raw Data** option specifies that the effectiveness (ε) is evaluated as the ratio of the rate of heat transfer between the primary and auxiliary fluids (which you define in a table format) to the maximum possible rate of heat transfer (q_{max}) for the current flow regime (see Equation 6.7 in the Theory Guide). The calculated efficiency is then used to calculate the NTU value using the crossflow formula for each and every set of primary and auxiliary flow rates.

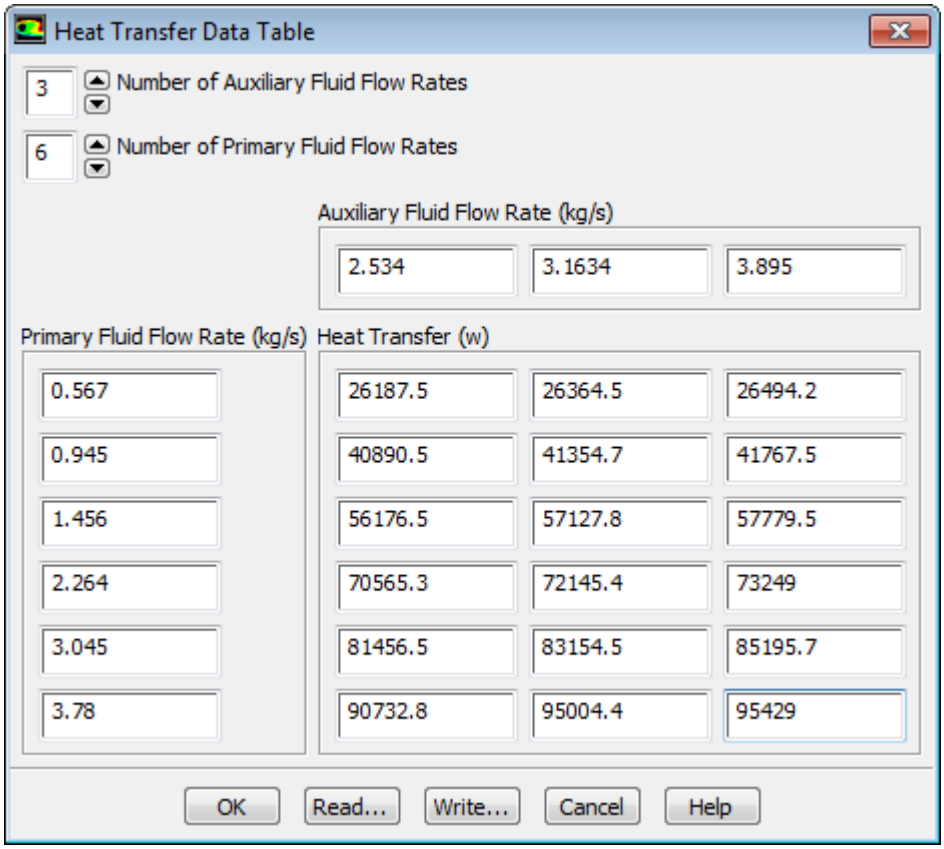
If the heat exchanger manufacturer used a similar approach in evaluating the NTU values, then there is no difference between the **Raw Data** and **NTU Data** options. However, if a different methodology was used by the manufacturer that accounts for some possible non-uniformity of the profile or for the partial mixing of the flow stream, then the **NTU Data** option is likely to be more accurate. Similarly, you may be able to assess more accurate NTU values for your case using tables from the relevant literature. This can even include some mixing of the oncoming flow stream, for situations where the primary flow can deviate from the direction normal to the heat exchanger tubes; this can happen in heat exchangers where the fins are either very spaced or absent. Therefore, the **NTU Data** option can be more accurate if the NTU values are gathered at non-ideal conditions that bear a close resemblance to your simulated scenario.

i. If you select the **Raw Data** option, then specify the following:

- **Heat Transfer Data...** opens the Heat Transfer Data Table Dialog Box (p. 2204), where you will enter experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 13.8: The Heat Transfer Data Table Dialog Box (p. 927)). See Specifying Heat Exchanger Performance Data (p. 937) more details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.8: The Heat Transfer Data Table Dialog Box



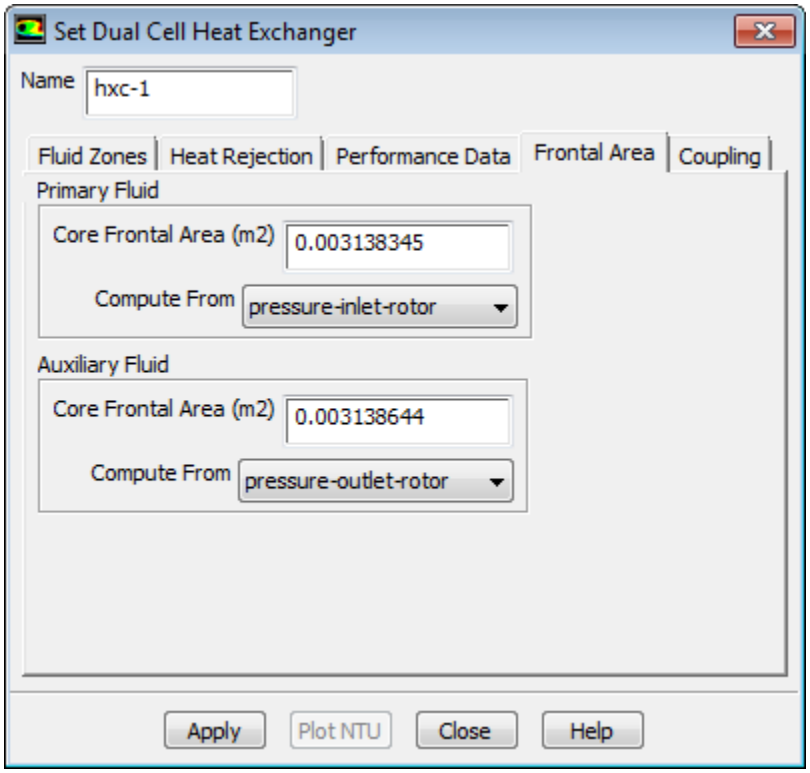
- **Effectiveness-NTU Relation** computes the NTU values from the heat transfer data. Choose **cross-flow-unmixed**, **parallel-flow**, or **counter-flow**, all of which are described in NTU Relations.
- **Auxiliary Fluid Temperature** is the inlet reference temperature for the auxiliary fluid.
- **Primary Fluid Temperature** is the inlet reference temperature for the primary fluid.

ii. If you select the **NTU Data** option, click **NTU Table...** to access the **NTU Table** dialog box. Populate this table in the same manner as described previously for the Heat Transfer Data Table Dialog Box (p. 2204). More information is available in Specifying Heat Exchanger Performance Data (p. 937).

e. Click the **Frontal Area** tab. You have the option to specify the **Primary** and **Auxiliary Fluid Core Frontal Area** directly, or compute the area from a surface zone, as shown in Figure 13.9: The Frontal Area Tab (p. 928).

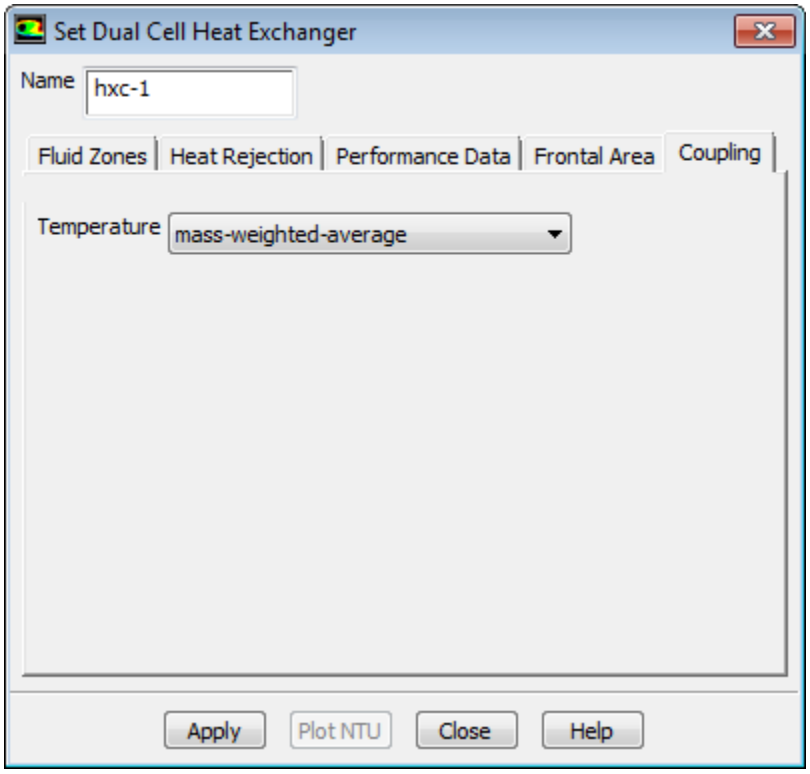
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.9: The Frontal Area Tab



f. Click the **Coupling** tab if you want to couple the heat exchanger passes (Figure 13.10: The Coupling Tab (p. 928)).

Figure 13.10: The Coupling Tab



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Consider the following example illustrating the coupling of a four-pass heat exchanger.

Figure 13.11: An Example of a Four-Pass Heat Exchanger

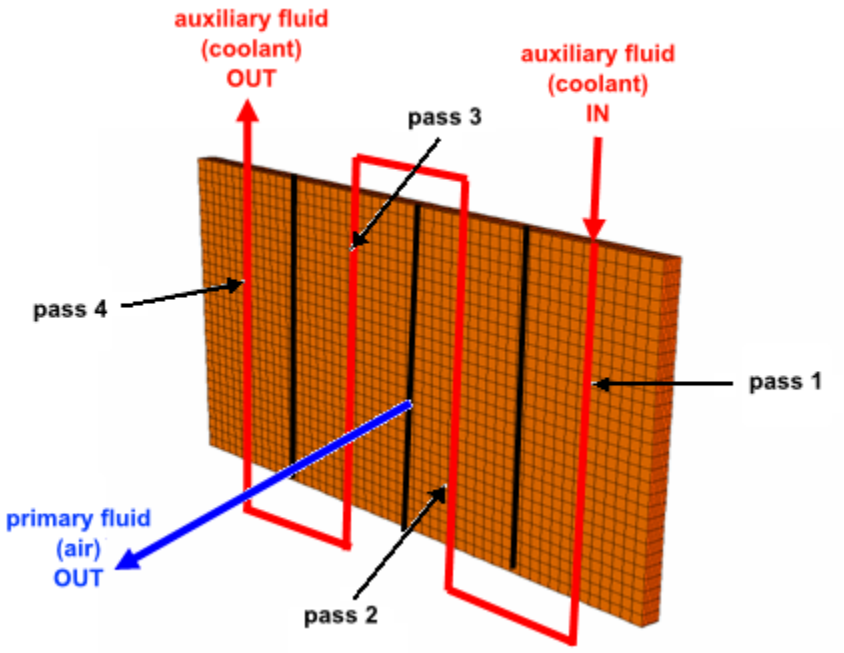


Figure 13.11: An Example of a Four-Pass Heat Exchanger (p. 929) shows a four-pass heat exchanger with air as the primary fluid and the coolant as the auxiliary fluid. The coolant flows through the tubes in a serpentine manner and air flows normal to the tubes, forming a cross flow pattern. To model this type of flow using the dual cell heat exchanger model, you must first generate the mesh. The mesh should contain the following:

i. A single primary cell zone.

ii. Four adjacent auxiliary cell zones, one for each pass. Each auxiliary zone should be separated from the other by a coupled or uncoupled wall. Each pass will have its own inlet and outlet zones.

iii. The primary and four auxiliary zones should overlap in physical space.

In the **Coupling** tab, **mass-weighted-average** is selected by default for the **Temperature** of the outlet of Pass 1 to the inlet of Pass 2. Similarly, the mass-weighted-average temperature of the outlet of Pass 2 will be applied at the inlet zone of Pass 3, and so on. Alternatively, you can couple the passes by using **Profiles...** in the **Boundary Conditions** task page or by using user-defined functions to define the **Temperature** in the **Thermal** tab of the relevant boundary condition dialog boxes. If you do so, make sure you select **none** from the **Temperature** drop-down list in the **Coupling** tab of the **Set Dual Heat Exchanger** dialog box.

Important

Make sure to specify the auxiliary zones in the correct order (that is the zone for Pass 1 should be selected first, then Pass 2, and so on) in the **Fluid Zones** tab of the **Set Dual Cell Heat Exchanger** dialog box.

g. Click **Apply** to save the heat exchanger inputs.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. To view the plot of NTU vs. primary mass flow rate for each auxiliary mass flow rate, click **Plot NTU**.

   The **Plot NTU** button will plot the performance data curve for the selected heat exchanger. The performance data is supplied through the **Performance Data** tab.

   When you close the **Set Dual Cell Heat Exchanger** dialog box, you will return to the **Dual Cell Heat Exchanger** dialog box, where you should now see the heat exchanger name in the **Heat Exchanger** list.

   You can

   - Modify the settings of heat exchanger by selecting it from the list and clicking **Modify...**.
   - Copy the data of one heat exchanger to another using the **Copy** button, assuming you have more than one heat exchanger.
   - Delete any unwanted heat exchangers by selecting the heat exchanger from the list and clicking **Delete**.

   Important

   All the inputs are copied except for the name, primary fluid zone and auxiliary fluid zone.

13.3. The Macro Heat Exchanger Models

To use the macro heat exchanger model, you must define one or more fluid zone(s) to represent the heat exchanger core. Typically, the fluid zone is sized to the dimension of the core itself. As part of the setup procedure, you will define the auxiliary fluid path, the number of macros, and the physical properties and operating conditions of the core (pressure drop parameters, heat exchanger effectiveness, auxiliary fluid flow rate, and so on).

Additional information about macro heat exchangers can be found in Overview of the Macro Heat Exchanger Models in the Theory Guide. For the theory behind these models, refer to Macro Heat Exchanger Model Theory in the Theory Guide.

ANSYS Fluent provides two heat transfer models: the default NTU model and the simple effectiveness model. The simple effectiveness model interpolates the effectiveness from the velocity vs. effectiveness curve that you provide. For the NTU model, ANSYS Fluent calculates the effectiveness, ε, from the NTU value that is calculated by ANSYS Fluent from the heat transfer data provided by you in tabular format. ANSYS Fluent will automatically convert this heat transfer data to a primary fluid mass flow rate vs. NTU curve (this curve will be piecewise linear). This curve will be used by ANSYS Fluent to calculate the NTU for macros based on their size and primary fluid flow rate.

The NTU model provides the following features:

- The model can be used to check heat capacity for both the primary and the auxiliary fluid and takes the lesser of the two for the calculation of heat transfer.
- The model can be used to model heat transfer to the primary fluid from the auxiliary fluid, and vice versa.
- The model can be used to model primary fluid-side reverse flow.
- The model can be used with variable density of the primary fluid.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The model can be used in either the serial or parallel ANSYS Fluent solvers.
- The model can be used to make a network of heat exchangers using a heat exchanger group (Using the Grouped Macro Heat Exchanger Model (p. 943)).
- Transient profiles can be used for the auxiliary fluid inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

The simple effectiveness model provides the following features:

- The model can be used to model heat transfer from the auxiliary fluid to the primary fluid, and vice versa.
- The auxiliary fluid properties can be a function of pressure and temperature, therefore allowing phase change of the auxiliary fluid.
- The model can be used by serial as well as parallel solvers.
- The model can be used to make a network of heat exchangers using a heat exchanger group (Using the Grouped Macro Heat Exchanger Model (p. 943)).
- Transient profiles can be used for the auxiliary fluid inlet temperature and for total heat rejection.
- Transient profiles can be used for auxiliary mass flow rates.

For additional information, see the following sections:

13.3.1. Restrictions
13.3.2. Using the Ungrouped Macro Heat Exchanger Model
13.3.3. Using the Grouped Macro Heat Exchanger Model

13.3.1. Restrictions

The following restrictions exist for the macro heat exchanger models:

- The core must be a 3D mesh with a cross-section that is approximately rectangular in shape.
- The primary fluid streamwise direction (see Equation 6.1 in the Theory Guide) must be aligned with one of the three orthogonal axes defined by the rectangular core.
- The pass-to-pass plane must be perpendicular to the primary fluid streamwise direction.
- The two dimensions of the pass-to-pass plane can each be discretized into multiple macroscopic cells (macros), but in the direction perpendicular to this plane the macros cannot be subdivided.
- It is highly recommended that the free-form **Tet** mesh is not used in the macro heat exchanger model. Instead, evenly distributed **Hex/Wedge** cells should be used for improved accuracy and a more robust solution process.
- Flow acceleration effects are neglected in calculating the pressure loss coefficient.
- For the simple effectiveness model, the primary fluid must have a capacity rate that is less than that of the auxiliary fluid.
- Auxiliary fluid phase change cannot be modeled using the NTU model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The macro-based method requires that an equal number of cells reside in each macro of equal size and shape.
- The auxiliary fluid flow is assumed to be 1D.
- The pass width has to be uniform.
- Accuracy is not guaranteed when the mesh is not structured or layered.
- Accuracy is not guaranteed when there is upstream diffusion of temperature at the inlet/outlet of the core.
- Non-conformal meshes cannot be attached to the inlet/outlet of the core. An extra layer has to be created to avoid it.

13.3.2. Using the Ungrouped Macro Heat Exchanger Model

The heat exchanger model settings may be written into and read from the boundary conditions file (Reading and Writing Boundary Conditions (p. 56)) using the text commands, `file/write-settings` and `file/read-settings`, respectively. Otherwise, the steps for setting up the ungrouped macro heat exchanger model is as follows:

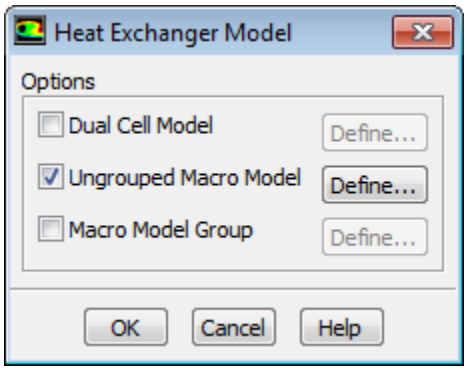
1. Read the mesh and make sure that the inlet and outlet for the heat exchanger are two separate zones.
2. Enable the calculation of energy in the Energy Dialog Box (p. 2175).

   Setup → Models → Energy **ON**

3. Enable the **Ungrouped Macro Model** option and click the **Define...** button in the Heat Exchanger Model Dialog Box (p. 2200) (Figure 13.12: The Heat Exchanger Model Dialog Box (p. 932)) to access the **Ungrouped Macro Heat Exchanger** dialog box.

   Setup → Models → Heat Exchanger **Edit...**

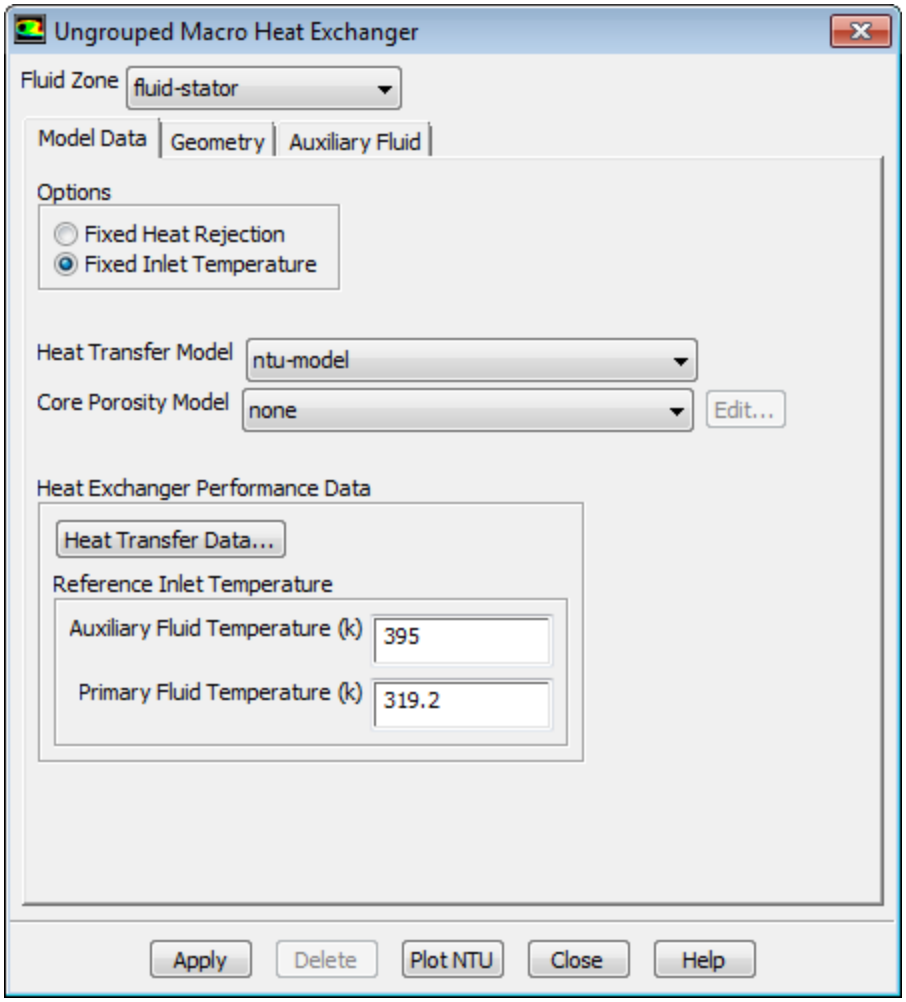
   Figure 13.12: The Heat Exchanger Model Dialog Box



4. Specify the heat exchanger inputs in the **Ungrouped Macro Heat Exchanger** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.13: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab



a. In the **Fluid Zone** drop-down list, select the fluid zone representing the heat exchanger core.

b. Under the **Model Data** tab, choose **Fixed Heat Rejection** or **Fixed Inlet Temperature**, as required (Figure 13.13: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab (p. 933)).

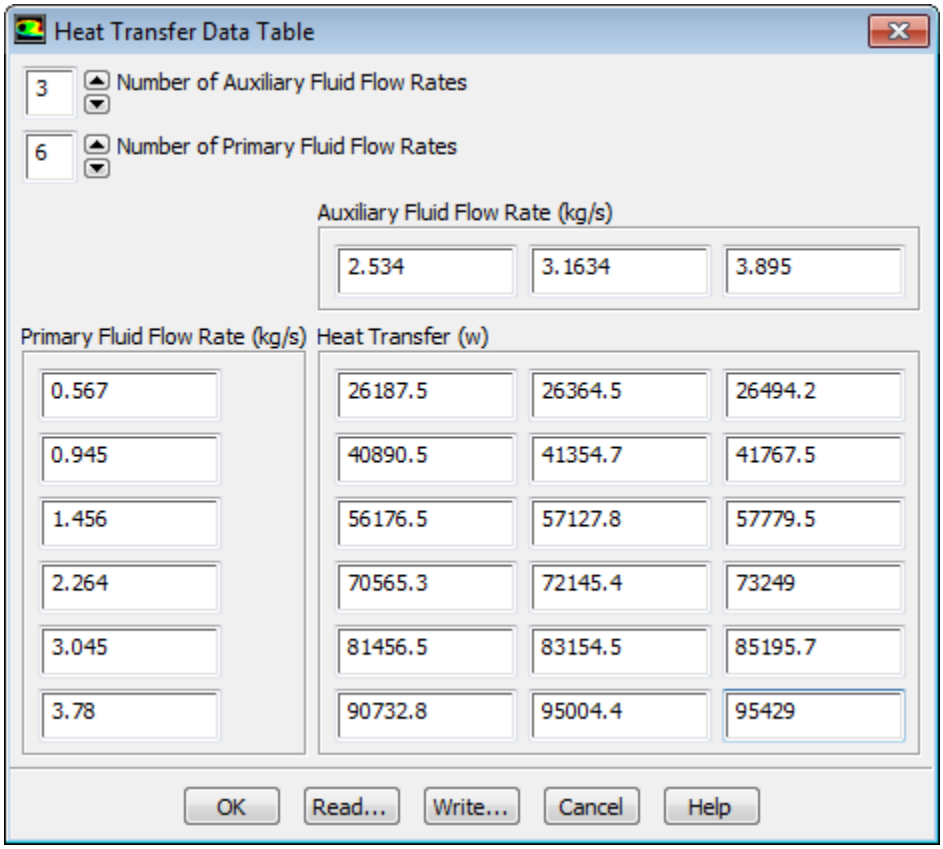
c. Specify the **Heat Transfer Model** as either the default **ntu-model** or the **simple-effectiveness-model**. See step 3 in Choosing a Heat Exchanger Model (p. 920) for details about the differences between these two models.

d. Specify the **Core Porosity Model** if you want ANSYS Fluent to use the pressure loss coefficient function to automatically compute (and update) the porous media coefficients in the cell zones condition dialog box, as described in Streamwise Pressure Drop in the Theory Guide. More information is available in Setting the Pressure-Drop Parameters and Effectiveness (p. 941).

e. If the **ntu-model** is chosen, a **Heat Transfer Data...** button will appear under **Heat Exchanger Performance Data**. Clicking the **Heat Transfer Data...** button will open the Heat Transfer Data Table Dialog Box (p. 2204), where you will enter experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 13.8: The Heat Transfer Data Table Dialog Box (p. 927)). See Specifying Heat Exchanger Performance Data (p. 937) more details.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.14: The Heat Transfer Data Table Dialog Box for the NTU Model



f. Enter the **Auxiliary Fluid Temperature** and the **Primary Fluid Temperature** for the **ntu-model**. These are the fixed inlet temperatures at which the test was performed to obtain the heat transfer data.

g. If the **simple-effectiveness-model** is chosen, then clicking the **Velocity Effectiveness Curve...** button, under the **Heat Exchanger Performance Data**, allows you to set the velocity and corresponding effectiveness for each point. More information is available in Specifying Heat Exchanger Performance Data (p. 937).

h. In the **Geometry** tab, define the heat exchanger macros using the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass** fields. The **Number of Rows/Pass** is along the auxiliary flow direction (height) and the **Number of Columns/Pass** is defined in the pass-to-pass (width) direction. Also, enter the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction**. You may want to snap the plane tool to either the inlet or outlet of the heat exchanger using the **Update from Plane Tool**. Note that the plane tool must be attached exactly and oriented so that its green arrow points in the auxiliary flow direction, and its blue arrow points in the pass-to-pass direction.

Important

To attach the plane tool exactly, exact coordinates (printed in the console by probing) of the three corner nodes must be entered in the plane tool (x0, x1, x2) in a specific order. Also, note that x0 to x1 is the auxiliary flow direction and x1 to x2 is the pass-to-pass direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

More information is available in Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 938) and Defining the Macros (p. 938).

Figure 13.15: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Geometry Tab

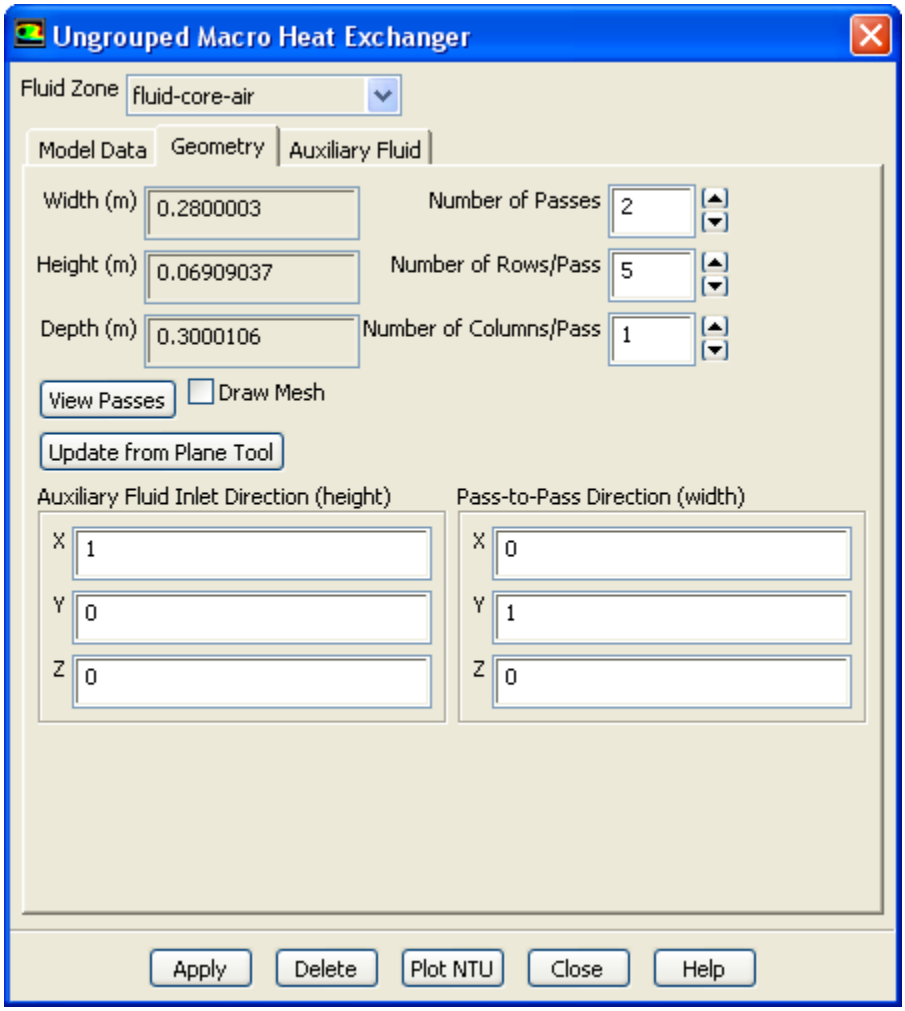


Figure 13.16: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Auxiliary Fluid Tab

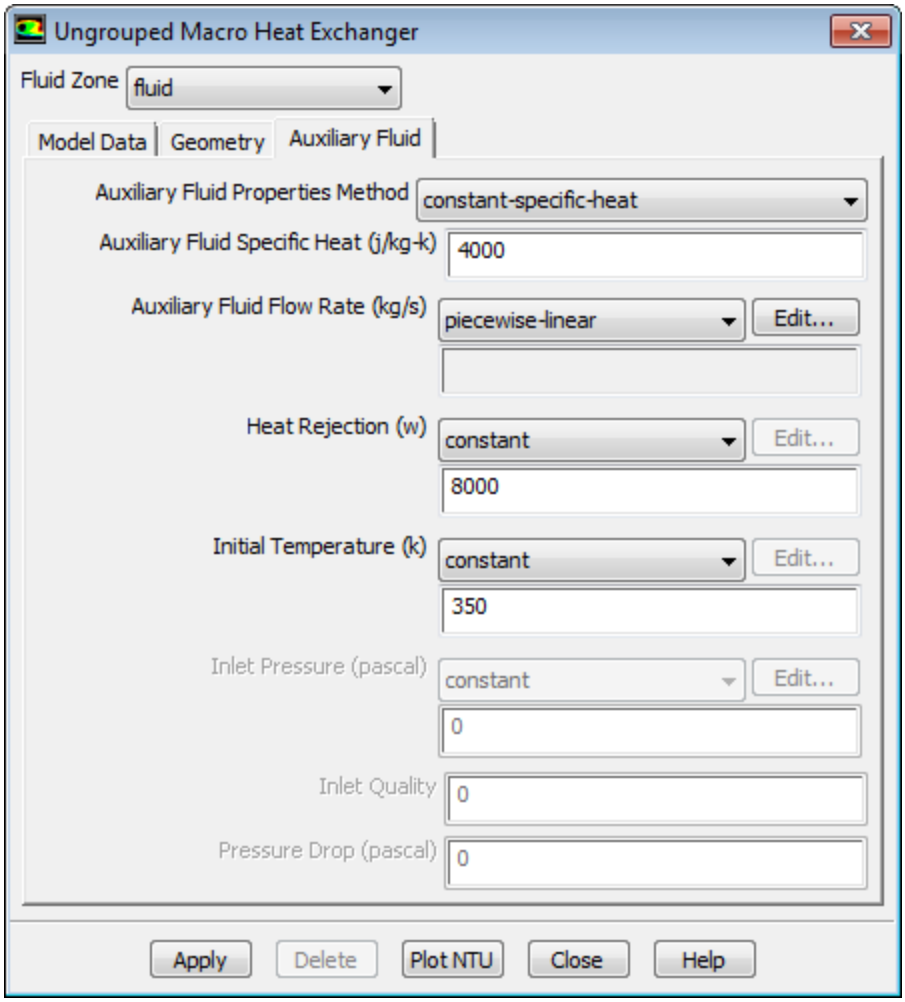


i. In the **Auxiliary Fluid** tab, specify the **Auxiliary Fluid Properties Method**, either as a **constant-specific-heat** or as a **user-defined-enthalpy**.

j. **Auxiliary Fluid Flow Rate**, **Heat Rejection**, **Inlet Temperature**, and **Inlet Pressure** can be provided as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time. If **user-defined-enthalpy** is selected as the **Auxiliary Fluid Properties Method**, you will need to specify the **Inlet Quality** and the **Pressure Drop**. More information is available in Specifying the Auxiliary Fluid Properties and Conditions (p. 940).

k. Click **Apply** in the **Ungrouped Macro Heat Exchanger** dialog box to save all the settings. Once you click the **Apply** button, the NTU matrix will be computed from the raw data. Therefore, make sure you click **Apply** at the very end of your setup.

Important

When you click **Apply**, look for any error or warning message in the ANSYS Fluent console. Some of the common errors you may see displayed are due to the NTU computations not converging. In such cases, check that

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- you have entered the data correctly
- the values of the data are reasonable
- the operating condition for the auxiliary fluid flow rate is not too far from the range of the heat transfer data

Other error messages you may encounter may be due to macros not getting any cells assigned to it. In such cases, make sure that

- the heat exchanger core is rectangular
- the directions are correct
- you are using uniformly spaced cells in both directions
- the mesh is either a hexahedra or wedge and is structured

l. Repeat steps (a)–(k) for any other heat exchanger fluid zones.

To use multiple fluid zones to define a single heat exchanger, or to connect the auxiliary fluid flow path among multiple heat exchangers, see Using the Grouped Macro Heat Exchanger Model (p. 943).

For additional information, see the following sections:
13.3.2.1. Selecting the Zone for the Heat Exchanger
13.3.2.2. Specifying Heat Exchanger Performance Data
13.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions
13.3.2.4. Defining the Macros
13.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions
13.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness

13.3.2.1. Selecting the Zone for the Heat Exchanger

Choose the fluid zone for which you want to define a heat exchanger in the **Fluid Zone** drop-down list.

13.3.2.2. Specifying Heat Exchanger Performance Data

Based on the heat transfer model you choose in the **Model Data** tab, some performance data must be entered for the heat exchanger.

- **ntu-model**: For the **ntu-model** you will provide the heat transfer for different primary and auxiliary fluid flow rates. Click the **Heat Transfer Data...** button to open up a tabular dialog box. Set the number of auxiliary flow rates and primary fluid flow rates. The dialog box will resize itself accordingly. You will need to provide various primary fluid flow rates and auxiliary fluid flow rates and the corresponding heat transfer values. You may write this data to a file that can be read later.
- **simple-effectiveness-model**: For this model, you will need to provide velocity versus effectiveness data. To provide this you can click the **Velocity Effectiveness Curve...** button. This will open up a tabular dialog box. In this dialog box, you can set the number of points in the curve, then you can provide velocities and corresponding effectiveness values (note that the effectiveness values must be within the range of 0–1). This data can be written to a file and read back.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13.3.2.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions

To define the auxiliary fluid direction and flow path, you will specify direction vectors for the **Auxiliary Fluid Inlet Direction** and the **Pass-to-Pass Direction** in the **Geometry** tab. Figure 13.17: 1x4x3 Macros (p. 939) shows these directions relative to the macros.

For some problems in which the principal axes of the heat exchanger core are not aligned with the coordinate axes of the domain, you may not know the auxiliary fluid inlet and pass-to-pass direction vectors a priori. In such cases, you can use the plane tool as follows to help you to determine these direction vectors.

1. "Snap" the plane tool onto the boundary of the heat exchanger core. (Follow the instructions in Initializing the Plane Tool (p. 1725) for initializing the tool to a position on an existing surface.)

2. Translate and rotate the axes of the tool appropriately until they are aligned with the principal directions of the heat exchanger core. The depth direction is determined by the red axis, the height direction by the green axis, and the width direction by the blue axis.

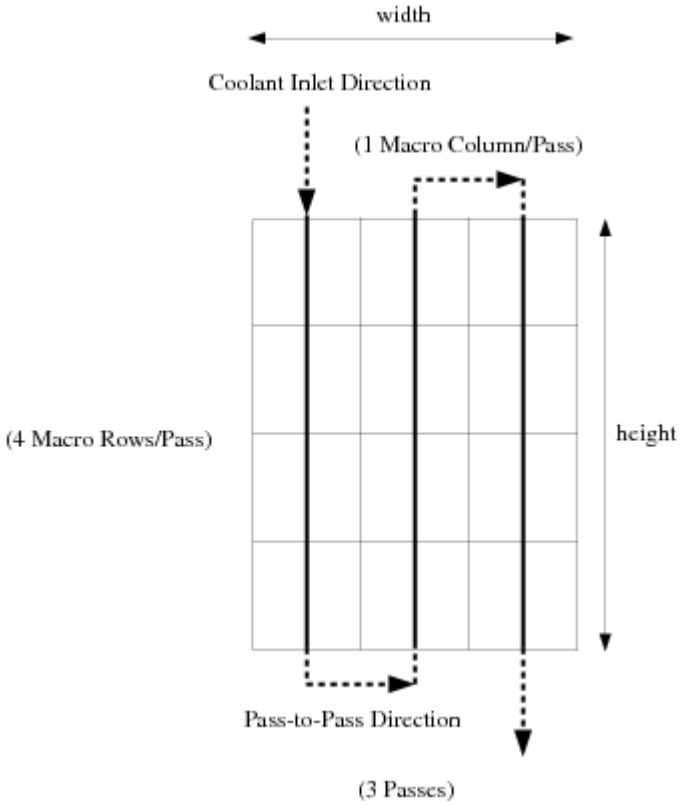
3. Once the axes are aligned, click the **Update from Plane Tool** button in the **Ungrouped Macro Heat Exchanger** dialog box. The directional vectors will be set automatically. (Note that the **Update from Plane Tool** button will also set the height, width, and depth of the heat exchanger core.)

13.3.2.4. Defining the Macros

As discussed in The Macro Heat Exchanger Models (p. 930), the fluid zone representing the heat exchanger core is split into macros. Macros are constructed based on the specified number of passes, the number of macro rows per pass, the number of macro columns per pass, and the corresponding auxiliary fluid inlet and pass-to-pass directions (see Figure 13.17: 1x4x3 Macros (p. 939)). Macros are numbered from 0 to $(n-1)$ in the direction of auxiliary fluid flow, where n is the number of macros.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.17: 1x4x3 Macros



In the **Ungrouped Macro Heat Exchanger** dialog box, in the **Geometry** tab, specify the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass**. The model will automatically extrude the macros to the depth of the heat exchanger core. For each pass, the **Number of Rows/Pass** are defined in the direction of the auxiliary flow inlet direction and the **Number of Columns/Pass** are defined in the direction of the pass-to-pass direction.

Important

The **Number of Rows/Pass**, as well as the **Number of Columns/Pass** must be divisible by the number of cells in their respective directions. For example, if you have 50 cells in the auxiliary flow direction, you can use 25 for the **Number of Rows/Pass**, but you should not use 26 or 24. If you have 51 cells in that direction, you can only use 51 for the **Number of Rows/Pass**. The same holds true for the other direction.

13.3.2.4.1. Viewing the Macros

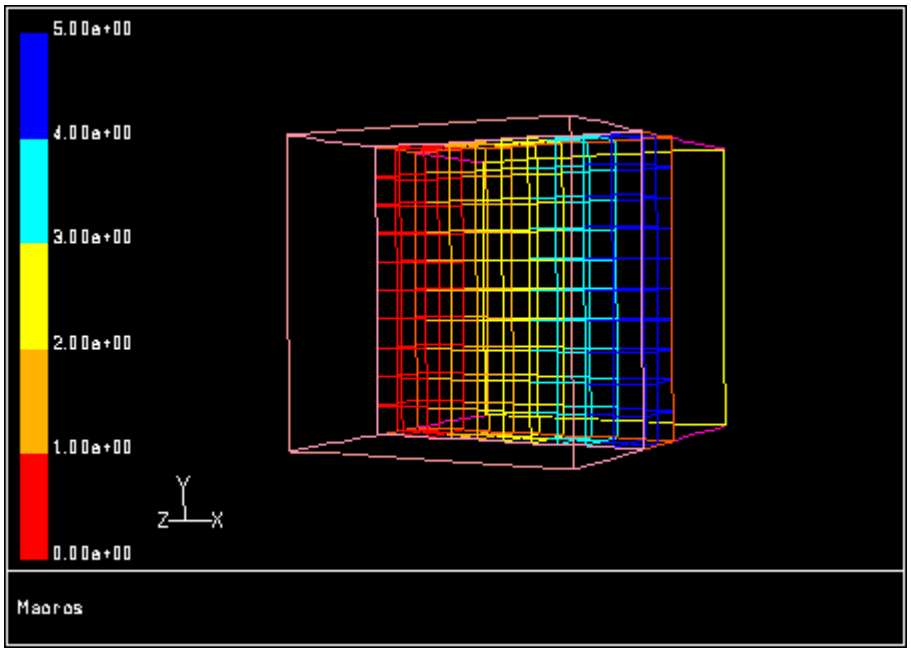
You can view the auxiliary fluid path by displaying the macros. To view the macros for your specified **Number of Passes**, **Number of Rows/Pass**, and **Number of Columns/Pass**, click the **Apply** button at the bottom of the dialog box, then click the **View Passes** button to display it. The path of the auxiliary fluid is color-coded in the display: macro 0 is red and macro $n-1$ is blue.

For some problems, especially complex geometries, you may want to include portions of the computational-domain mesh in your macros plot as spatial reference points. For example, you may want to show the location of an inlet and an outlet along with the macros. This is accomplished by enabling the **Draw Mesh** option. The Mesh Display Dialog Box (p. 2163) will appear automatically when you enable the **Draw Mesh** option, where you can set the mesh display parameters. When you click the **View Passes** button

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in the **Ungrouped Macro Heat Exchanger** dialog box, the mesh display, as defined in the **Mesh Display** dialog box, will be included in the macros plot (see Figure 13.18: Mesh Display With Macros (p. 940)).

Figure 13.18: Mesh Display With Macros



13.3.2.5. Specifying the Auxiliary Fluid Properties and Conditions

To define the auxiliary fluid properties and conditions, you will specify the **Auxiliary Fluid Flow Rate** ($\dot{m}$) in the **Auxiliary Fluid** tab. The properties of the auxiliary fluid can be specified using the **Auxiliary Fluid Properties Method** drop-down list. You can choose a **constant-specific-heat** (c_p) and set the value in the **Auxiliary Fluid Specific Heat** field below, or as a user-defined function for the enthalpy using the **user-defined-enthalpy** option and selecting the corresponding UDF from the **Auxiliary Fluid Enthalpy UDF** drop-down list.

The function should return a single value depending on the index:

- Enthalpy for given values of temperature, pressure, and quality.
- Temperature for given values of enthalpy and pressure
- Specific heat for given values of temperature and pressure

The user-defined function should be of type

```
DEFINE_SOURCE(udf_name, cell_t c, Thread *t, real d[n], int index).
```

where `n` in the expression `d[n]` would be `0` for temperature, `1` for pressure, or `2` for quality. The variable `index` is `0` for enthalpy, `1` for temperature, or `2` for specific heat. This user-defined function should return

```
real value; /* (temperature or enthalpy or Cp depending on index). */
```

- If you want ANSYS Fluent to compute the auxiliary fluid inlet temperature for a specified heat rejection, follow the steps below:

  1. Enable the **Fixed Heat Rejection** option in the **Model Data** tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Specify the **Heat Rejection** (q_{total} in Equation 6.15 in the Theory Guide) in the **Auxiliary Fluid** tab.

3. Specify the **Initial Temperature**, which will be used by ANSYS Fluent as an initial guess for the inlet temperature ($T_{in,auxiliary}$ in Equation 6.11 and Equation 6.13 in the Theory Guide).

- If you want ANSYS Fluent to compute the total heat rejection of the core for a given inlet auxiliary fluid temperature, follow the steps below:

  1. Enable the **Fixed Inlet Temperature** option in the **Model Data** tab.

  2. Specify the **Inlet Temperature** ($T_{in,auxiliary}$ in Equation 6.11 and Equation 6.13 in the Theory Guide) in the **Auxiliary Fluid** tab.

- If you enable the **User Defined Enthalpy** option under the **Auxiliary Fluid Properties Method**, you must also specify the **Inlet Pressure** (p_{in} in Equation 6.21 in the Theory Guide) and **Inlet Quality** (x in Equation 6.20 in the Theory Guide).

13.3.2.6. Setting the Pressure-Drop Parameters and Effectiveness

The pressure drop parameters and effectiveness define the **Core Porosity Model**. If you would like ANSYS Fluent to set the porosity of this a heat exchanger zone using a particular core model, you can select the appropriate model. This will automatically set the porous media inputs. There are three ways to specify the **Core Porosity Model** parameters:

- Use the values in ANSYS Fluent's default model.
- Define a new core porosity model with your own values.
- Read a core porosity model from an external file.

If you do not choose a core porosity model, you will need to set the porosity parameters in the cell zone conditions dialog box for the heat exchanger zone(s). To do this, follow the procedures described in User Inputs for Porous Media (p. 267).

The models you define will be saved in the case file.

13.3.2.6.1. Using the Default Core Porosity Model

ANSYS Fluent provides a default model for a typical heat exchanger core. The **default-model** core porosity model is a list of constant values from the **Ungrouped Macro Heat Exchanger** dialog box. These constants are used for setting the porous media parameters. To use these values, simply retain the selection of **default-model** in the **Core Porosity Model** drop-down list in the **Ungrouped Macro Heat Exchanger** dialog box. (You can view the default parameters as described below.)

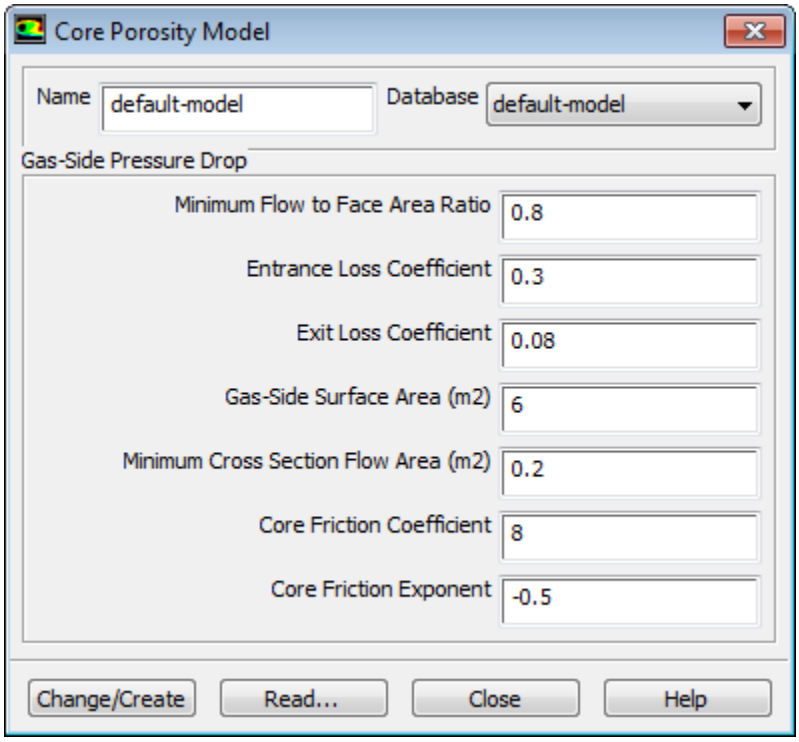
13.3.2.6.2. Defining a New Core Porosity Model

If you want to define pressure-drop and effectiveness parameters that are different from those in the default core porosity model, you can create a new model. The steps for creating a new model are as follows:

1. Click the **Edit...** button to the right of the **Core Porosity Model** drop-down list, for which **default-model** should have been selected. This will open the Core Porosity Model Dialog Box (p. 2211) (Figure 13.19: The Core Porosity Model Dialog Box (p. 942)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.19: The Core Porosity Model Dialog Box



2. Enter the name of your new model in the **Name** box at the top of the dialog box.

3. Under **Gas-Side Pressure Drop**, specify the following parameters used in Equation 6.2 in the Theory Guide:

   - **Minimum Flow to Face Area Ratio** (σ)
   - **Entrance Loss Coefficient** (K_c)
   - **Exit Loss Coefficient** (K_e)
   - **Gas-Side Surface Area** (A)
   - **Minimum Cross Section Flow Area** (A_c)

   and the **Core Friction Coefficient** and **Core Friction Exponent** (a and b, respectively, in Equation 6.3 in the Theory Guide).

4. Click the **Change/Create** button. This will add your new model to the database.

13.3.2.6.3. Reading Heat Exchanger Parameters from an External File

You can read parameters for your **Core Porosity Model** from an external file. A sample file is shown below:

```
("modelname"
 (0.73 0.43 0.053 5.2 0.33 9.1 0.66))
```

The first entry in the file is the name of the model (for example, `modelname`). The second set of numbers contains the gas-side (primary-side) pressure drop parameters:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$(\sigma\ K_c\ K_e\ A\ A_c\ a\ b)$

To read an external heat exchanger file, you will follow these steps:

1. In the **Core Porosity Model** dialog box, click the **Read...** button.

2. In the resulting **Select File** dialog box, specify the **HXC Parameters File** name and click **OK**. ANSYS Fluent will read the core porosity model parameters, and add the new model to the database.

13.3.2.6.4. Viewing the Parameters for an Existing Core Model

To view the parameters associated with a core porosity model that you have already defined, select the model name in the **Database** drop-down list (in the **Core Porosity Model** dialog box). The values for that model from the database will be displayed in the **Core Porosity Model** dialog box.

13.3.3. Using the Grouped Macro Heat Exchanger Model

To define a single heat exchanger that uses multiple fluid zones, or to connect the auxiliary fluid flow path among multiple heat exchangers, you can use heat exchanger groups. To use heat exchanger groups, perform the following steps:

1. Read the mesh and make sure that the inlet and outlet for the heat exchanger are two separate zones.

2. Enable the calculation of energy in the Energy Dialog Box (p. 2175).

   Setup → Models → Energy → ON

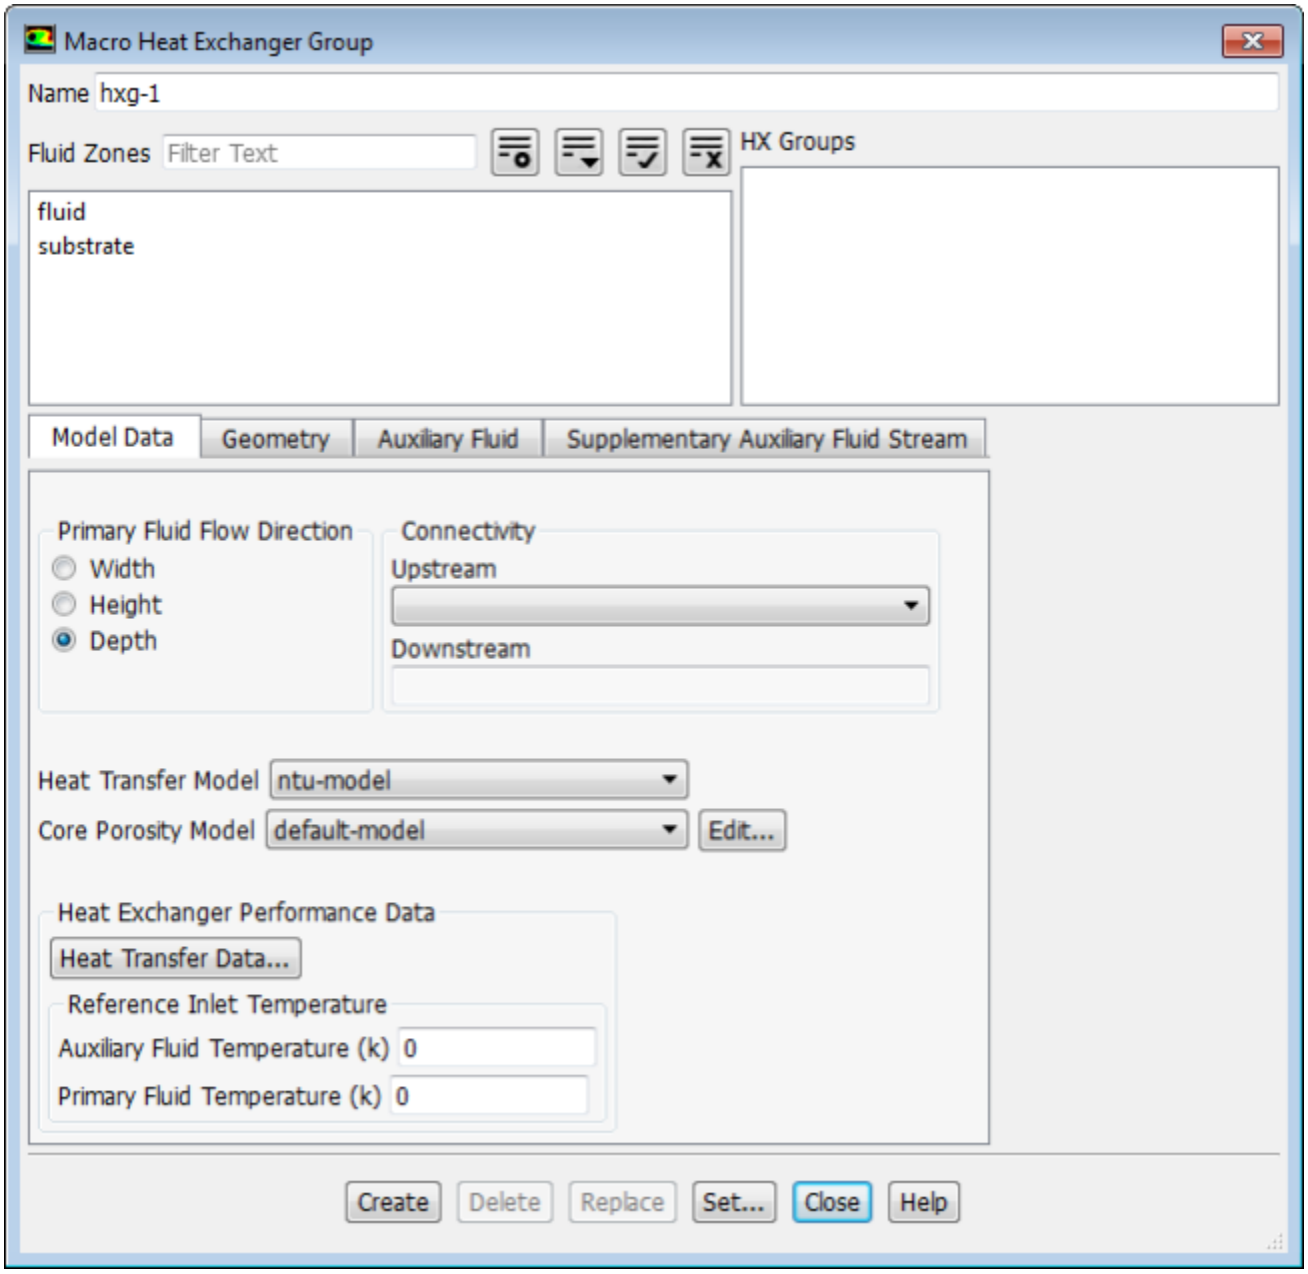
3. Enable the **Macro Model Group** option and click the **Define...** button in the Heat Exchanger Model Dialog Box (p. 2200) to access the **Macro Heat Exchanger Group** dialog box.

   Setup → Models → Heat Exchanger → Edit...

4. Specify the inputs to the heat exchanger group in the **Macro Heat Exchanger Group** dialog box (Figure 13.20: The Macro Heat Exchanger Group Dialog Box (p. 944)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.20: The Macro Heat Exchanger Group Dialog Box



a. Enter the **Name** of the heat exchanger group.

b. Under **Fluid Zones**, select the fluid zones that you want to define in the heat exchanger group (Selecting the Fluid Zones for the Heat Exchanger Group (p. 949)).

c. Click the **Model Data** tab.

   i. Under **Primary Fluid Flow Direction**, specify the primary fluid flow direction as either **Width**, **Height**, or **Depth**.

   ii. Under **Connectivity**, select the **Upstream** heat exchanger group if such a connection exists (see Selecting the Upstream Heat Exchanger Group (p. 949)).

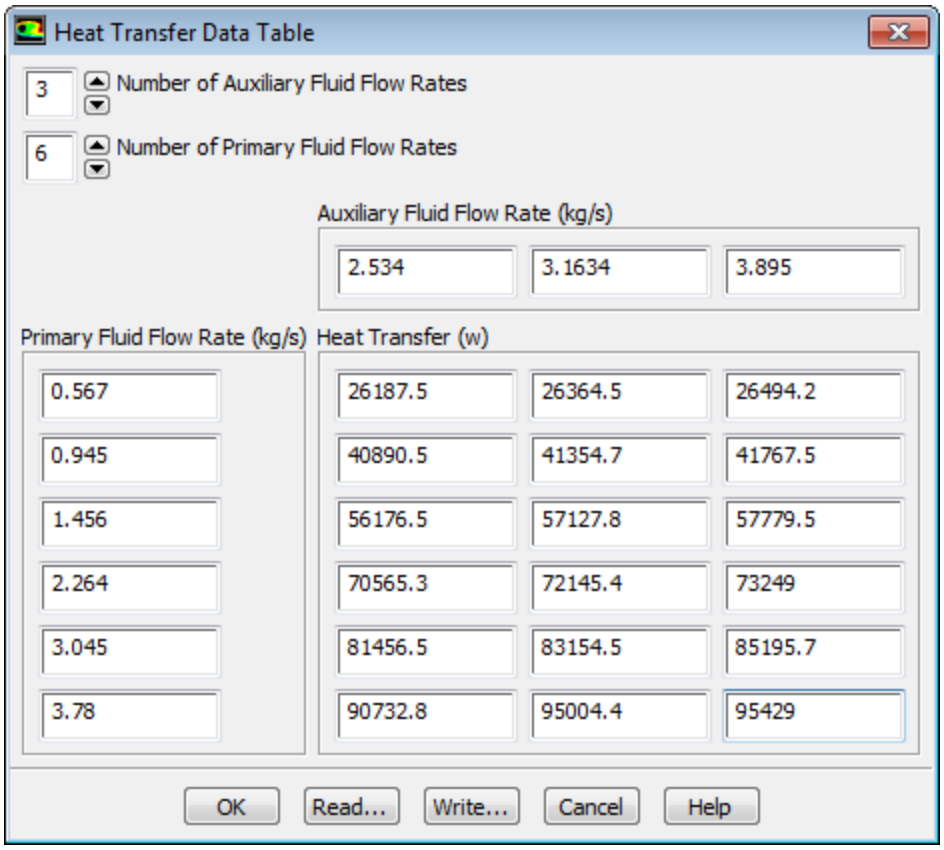
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iii. In the **Heat Transfer Model** drop-down list, choose either the **ntu-model** or the **simple-effectiveness-model**. See step 3 in Choosing a Heat Exchanger Model (p. 920) for details about the differences between these two models.

iv. From the **Core Porosity Model** drop-down list, specify the core model that should be used to calculate the porous media parameters for the zones in the group. More information is available in Setting the Pressure-Drop Parameters and Effectiveness (p. 941).

v. If the **ntu-model** is chosen, a **Heat Transfer Data...** button will appear under **Heat Exchanger Performance Data**. Clicking the **Heat Transfer Data...** button will open the Heat Transfer Data Table Dialog Box (p. 2204), where you will enter experimental data that defines how heat transfer values relate to the fluid flow rates (Figure 13.8: The Heat Transfer Data Table Dialog Box (p. 927)). See Specifying Heat Exchanger Performance Data (p. 937) more details.

Figure 13.21: The Heat Transfer Data Table Dialog Box for the NTU Model



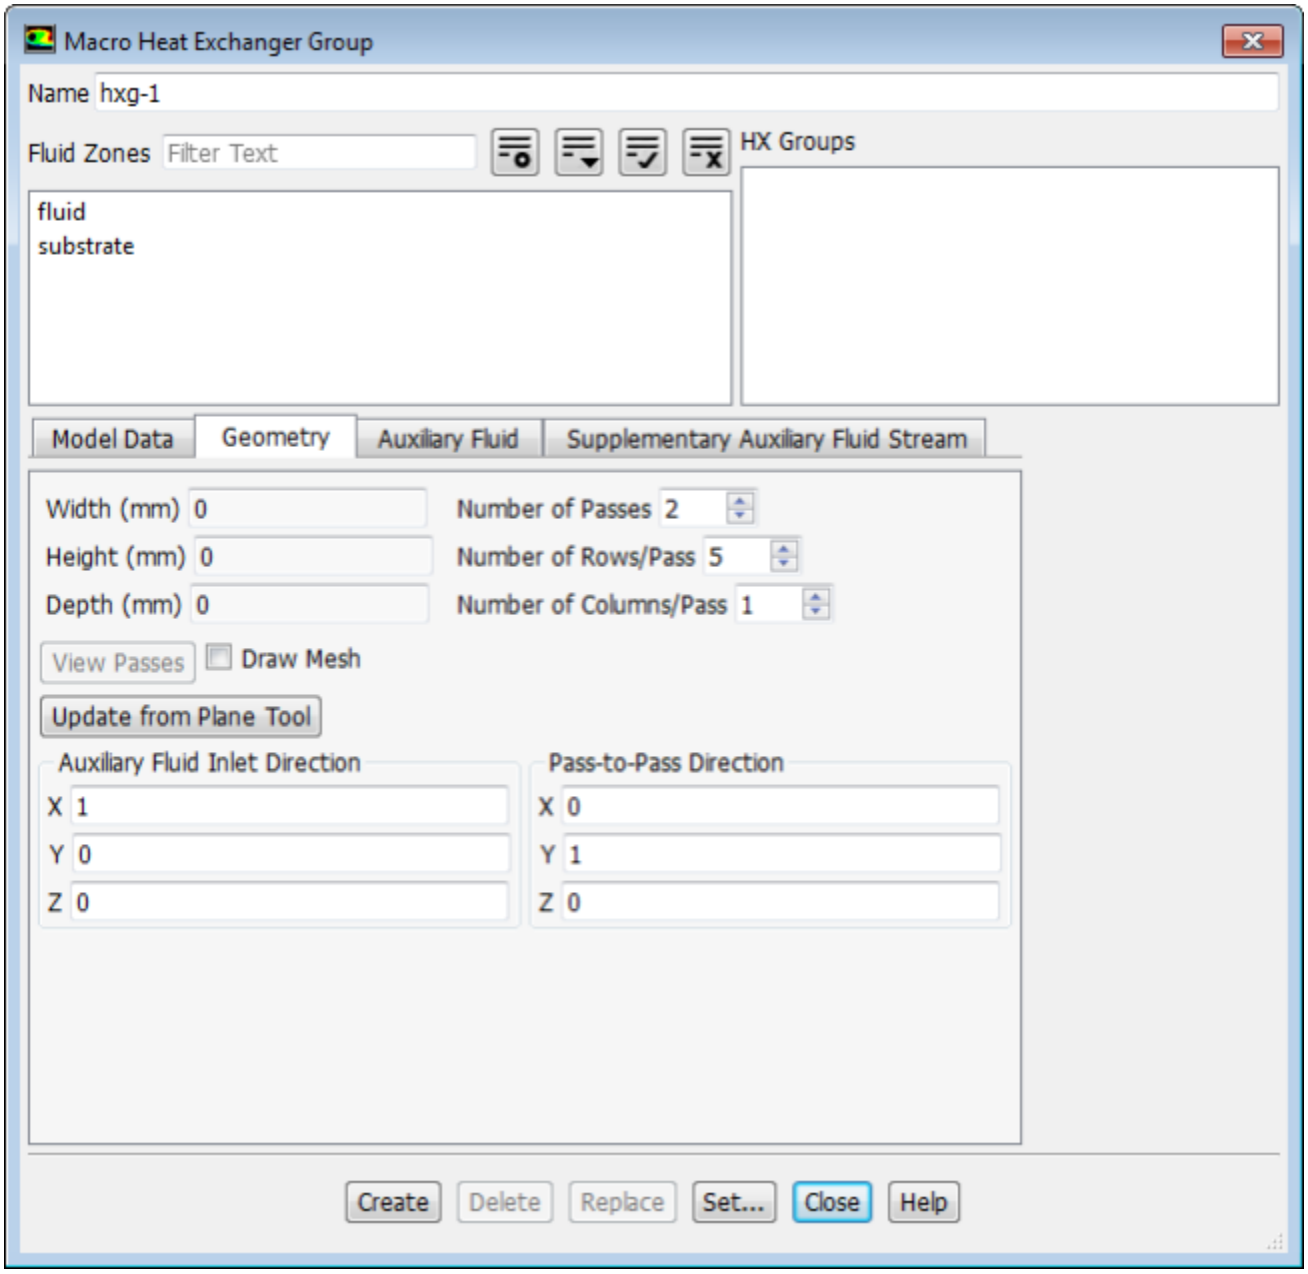
vi. Enter the **Auxiliary Fluid Temperature** and the **Primary Fluid Temperature** for the **ntu-model**. These are the fixed inlet temperatures at which the test was performed to obtain the heat transfer data.

vii. If the **simple-effectiveness-model** is chosen, then clicking the **Velocity Effectiveness Curve...** button, under the **Heat Exchanger Performance Data**, allows you to set the velocity and corresponding effectiveness for each point. More information is available in Specifying Heat Exchanger Performance Data (p. 937).

d. Click the **Geometry** tab (Figure 13.22: The Macro Heat Exchanger Group Dialog Box - Geometry Tab (p. 946)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.22: The Macro Heat Exchanger Group Dialog Box - Geometry Tab



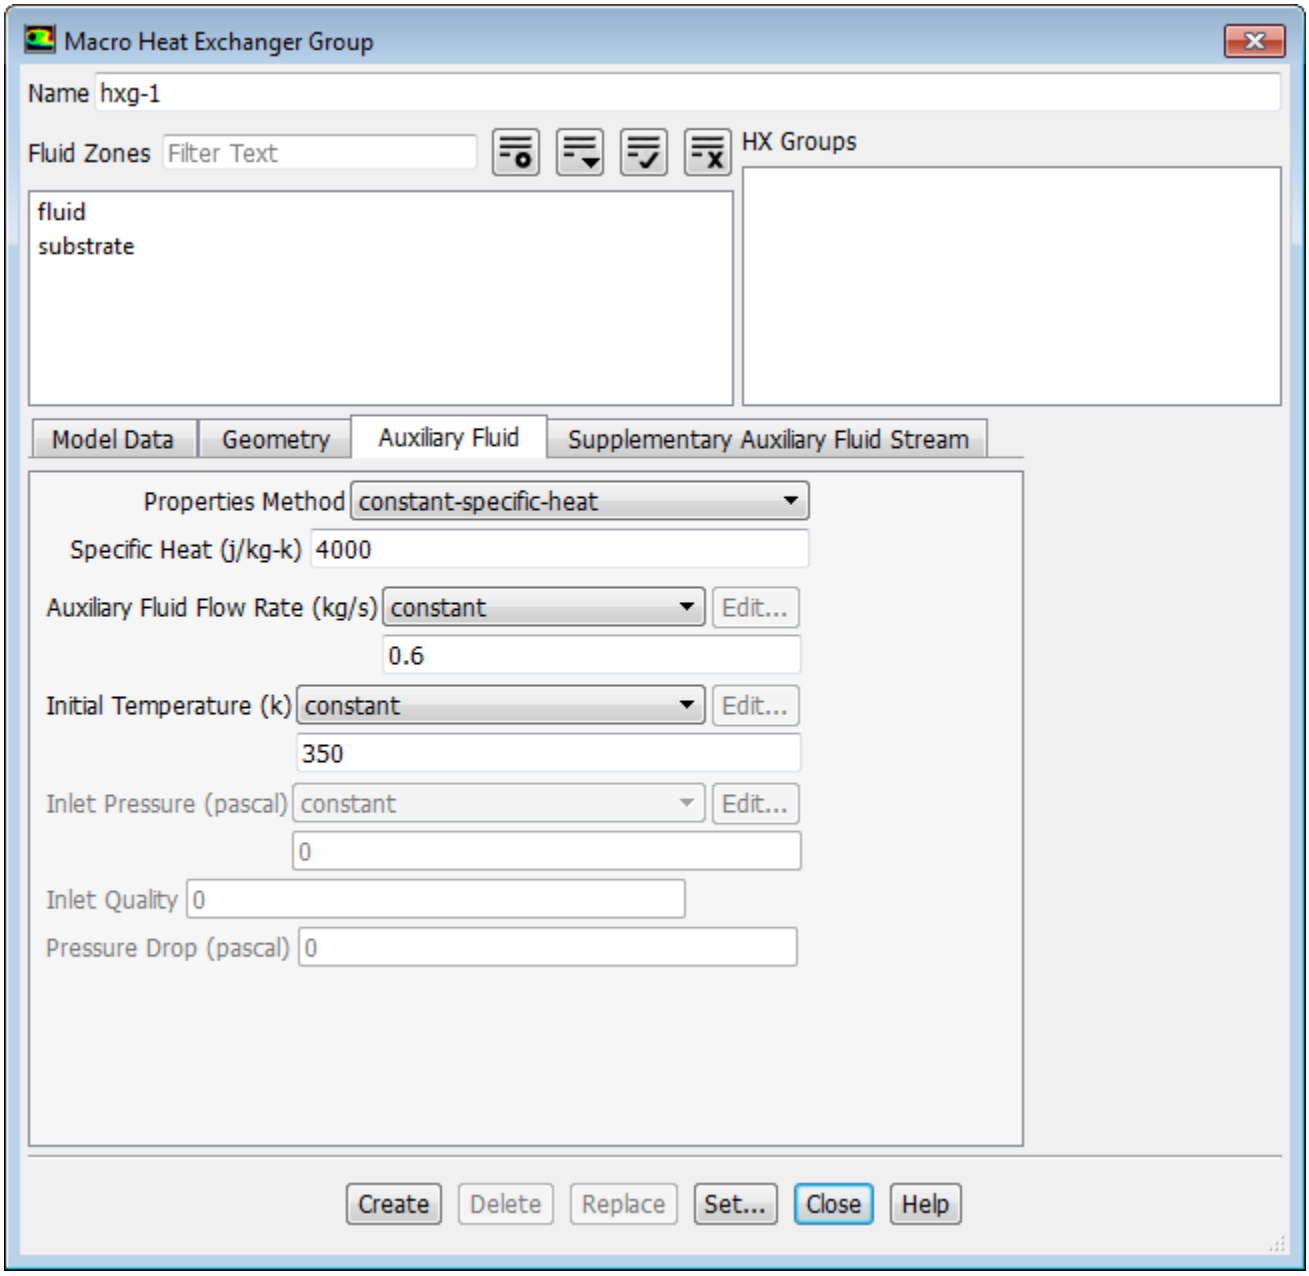
i. Define the heat exchanger macros by specifying the **Number of Passes**, the **Number of Rows/Pass**, and the **Number of Columns/Pass**. More information is available in Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 938) and Defining the Macros (p. 938).

ii. Specify the **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction** (see Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 950)).

e. Click the **Auxiliary Fluid** tab (Figure 13.23: The Macro Heat Exchanger Group Dialog Box - Auxiliary Fluid Tab (p. 947)) to specify the auxiliary fluid operating conditions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.23: The Macro Heat Exchanger Group Dialog Box - Auxiliary Fluid Tab



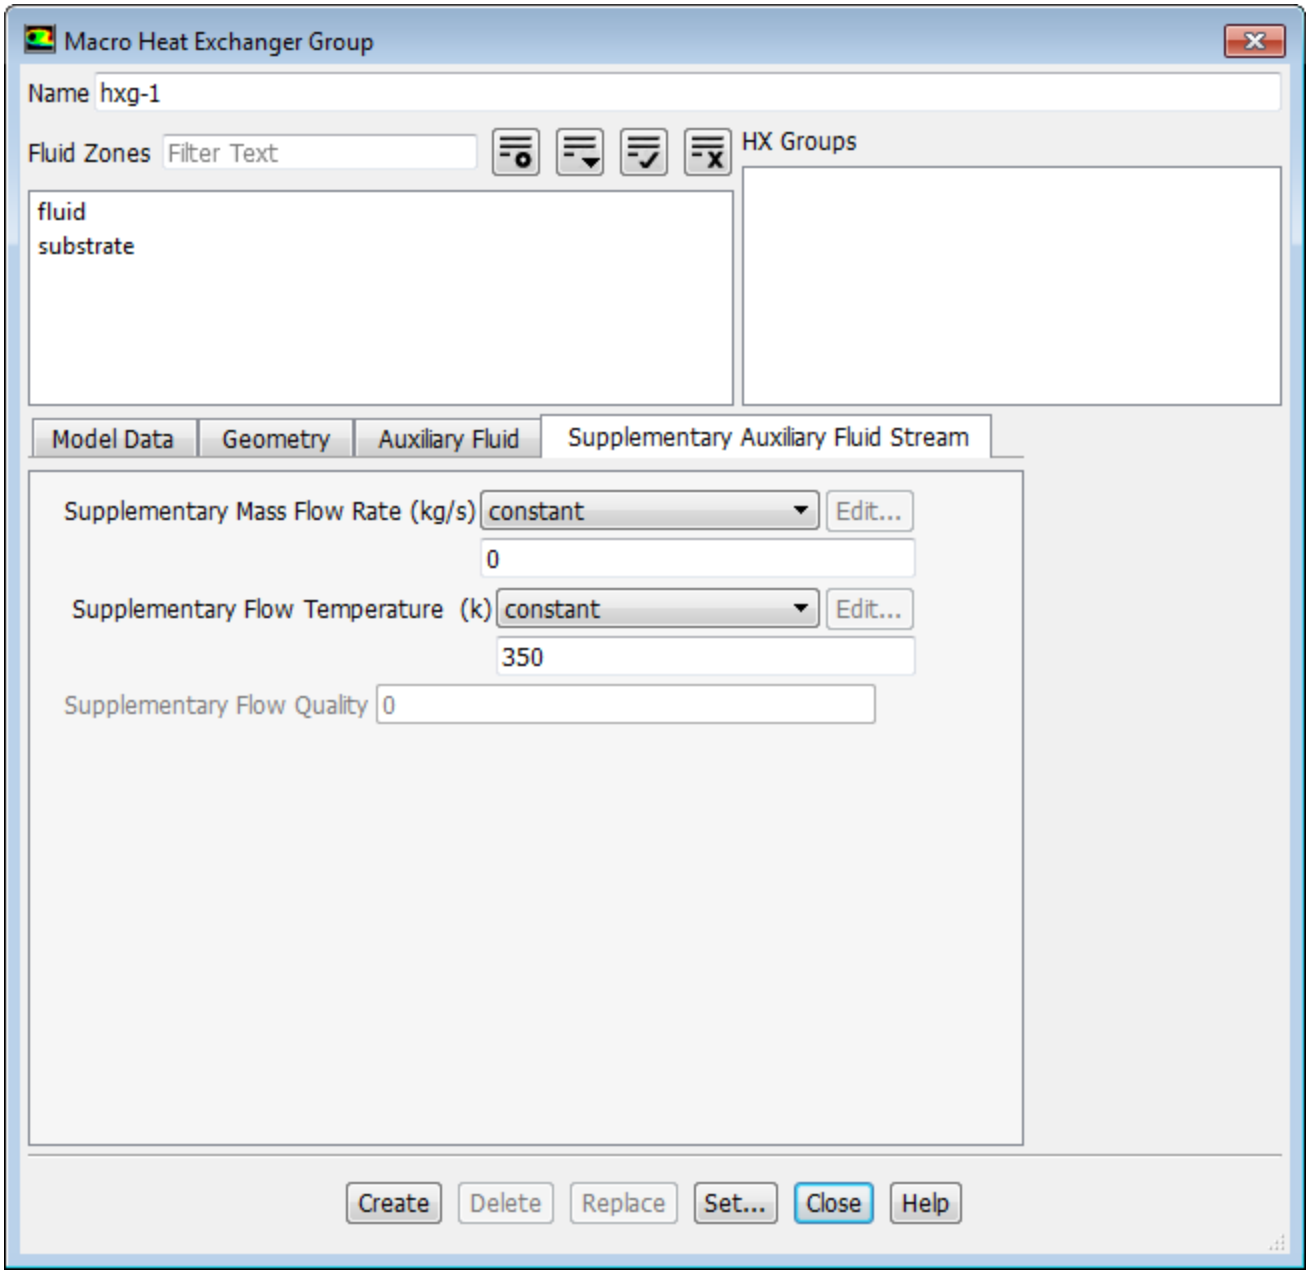
i. Specify the **Specific Heat** as either a **constant-specific-heat** or as a **user-defined-enthalpy**.

ii. **Auxiliary Fluid Flow Rate**, **Initial Temperature**, and **Inlet Pressure** can be provided as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time (see Specifying the Auxiliary Fluid Properties and Conditions (p. 940)).

f. If a supplementary auxiliary stream is to be modeled, click the **Supplementary Auxiliary Fluid Stream** tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.24: The Macro Heat Exchanger Group Dialog Box - Supplementary Auxiliary Fluid Stream Tab



i. You can specify the **Supplementary Mass Flow Rate** as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time.

ii. You can specify the **Supplementary Flow Temperature** as a **constant**, **polynomial** or **piecewise-linear** profile that is a function of time.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

g. Click **Create** or **Replace** in the **Macro Heat Exchanger Group** dialog box to save all the settings. **Replace** changes the parameters of the already existing group that is selected in the **HX Groups** list.

> **Important**
>
> Creating or replacing any heat exchanger group initializes any previously calculated values for temperature and enthalpy for all macros.

5. If a heat exchanger group comprises multiple fluid zones and you want to override any of the inputs defined in the previous steps, click the **Set...** button to open the **Ungrouped Macro Heat Exchanger** dialog box (Figure 13.13: The Ungrouped Macro Heat Exchanger Dialog Box Displaying the Model Data Tab (p. 933)). Select the particular fluid zone as usual. Notice that the individual heat exchanger inherits the properties of the group by default. You may override any of the following:

   - **Number of Passes**, **Number of Rows/Pass**, and **Number of Columns/Pass**
   - **Auxiliary Fluid Inlet Direction** and the **Pass-to-Pass Direction**
   - **Core Porosity Model**

For additional information, see the following sections:

13.3.3.1. Selecting the Fluid Zones for the Heat Exchanger Group
13.3.3.2. Selecting the Upstream Heat Exchanger Group
13.3.3.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions
13.3.3.4. Specifying the Auxiliary Fluid Properties
13.3.3.5. Specifying Supplementary Auxiliary Fluid Streams
13.3.3.6. Initializing the Auxiliary Fluid Temperature

13.3.3.1. Selecting the Fluid Zones for the Heat Exchanger Group

Select the fluid zones that you want to define in the heat exchanger group in the **Fluid Zones** drop-down list. The auxiliary fluid flow in all these zones will be in parallel. Note that one zone cannot be included in more than one heat exchanger group.

13.3.3.2. Selecting the Upstream Heat Exchanger Group

If you want to connect the current group in series with another group, choose the upstream heat exchanger group. Note that any group can have at most one upstream and one downstream group. Also, a group cannot be connected to itself. Select a heat exchanger group from the **Upstream** drop-down list under **Connectivity** in the **Model Data** tab of the **Macro Heat Exchanger Group** dialog box.

> **Important**
>
> Connecting to an upstream heat exchanger group can be done only while creating a heat exchanger group. The connection will persist even if the connection is later changed and the **Replace** button is clicked. To change a connection to an upstream heat exchanger group, you need to delete the connecting group and create a new heat exchanger group with the proper connection.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

13.3.3.3. Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions

The **Auxiliary Fluid Inlet Direction** and **Pass-to-Pass Direction**, in the **Geometry** tab can be specified as directed in Specifying the Auxiliary Fluid Inlet and Pass-to-Pass Directions (p. 938) in the **Ungrouped Macro Heat Exchanger** dialog box. Note that the **Update from Plane Tool** will set the height, width, and depth as the average of the fluid zones selected in the **Fluid Zones**.

13.3.3.4. Specifying the Auxiliary Fluid Properties

The auxiliary fluid can be specified as having a **constant-specific-heat**, or a user-defined function can be written to calculate the enthalpy, as described in Specifying the Auxiliary Fluid Properties and Conditions (p. 940).

13.3.3.5. Specifying Supplementary Auxiliary Fluid Streams

The addition or removal of a supplementary auxiliary fluid is allowed in any of the heat exchanger groups. Note that auxiliary streams are not allowed for individual zones. You will specify the mass flow rate, temperature, and quality of the supplementary auxiliary fluid. You will also need to specify the heat transfer for various flow rates of primary and auxiliary flows. The auxiliary stream has the following assumptions:

- The magnitude of a negative auxiliary stream must be less than the primary auxiliary fluid inlet flow rate of the heat exchanger group.
- Added streams will be assumed to have the same fluid properties as the primary inlet auxiliary fluid.

13.3.3.6. Initializing the Auxiliary Fluid Temperature

When the heat exchanger group is connected to an upstream heat exchanger group, ANSYS Fluent will automatically set the initial guess for the auxiliary fluid inlet temperature, $T_{in,auxiliary}$, to be equal to the $T_{in,auxiliary}$ of the upstream heat exchanger group. Thus the boundary condition $T_{in,auxiliary}$ for the first heat exchanger group in a connected series will automatically propagate as an initial guess for every other heat exchanger group in the series. However, when it is necessary to further improve convergence properties, you will be allowed to override $T_{in,auxiliary}$ for any connected heat exchanger group by providing a value in the **Initial Temperature** field. Whenever such an override is supplied, ANSYS Fluent will automatically propagate the new $T_{in,auxiliary}$ to any heat exchanger groups further downstream in the series. Similarly, every time the $T_{in,auxiliary}$ boundary condition for the first heat exchanger group is modified, ANSYS Fluent will correspondingly update every downstream heat exchanger group.

If you want to impose a non-uniform initialization on the auxiliary fluid temperature field, first connect the heat exchanger groups and then set $T_{in,auxiliary}$ for each heat exchanger group in streamwise order.

All heat exchangers included in a group must use the fixed $T_{in,auxiliary}$ option. All heat exchangers within a heat exchanger group must have the same $T_{in,auxiliary}$. In other words, no local override of this setting is possible through the **Ungrouped Macro Heat Exchanger** dialog box.

13.4. Postprocessing for the Heat Exchanger Model

Postprocessing for the heat exchanger models involves computing the total heat rejection rate by setting up volume monitors and reporting of variables such as computed heat rejection, inlet or outlet temperature, specific heat, and mass flow rate.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that when postprocessing dual cell heat exchanger models using dialog boxes other than the **Heat Exchanger Report** dialog box (which requires you to explicitly specify whether you want reports on either the **Primary** or the **Auxiliary** fluid), attention must be paid to the fact that there are overlapping cell zones in the heat exchanger region. For example:

- When creating an isosurface and making selections from the **From Zones** selection list of the **Iso-Surface** dialog box, you should never select both the primary and the auxiliary fluid zones at the same time. Note that if no selections are made in this list, then all the cell zones are selected.
- When making selections from the **Surfaces** list of the **Contours** dialog box, you should not select a surface that is associated with the primary fluid zone and a surface associated with the auxiliary fluid zone at the same time, if those surfaces are spatially coincident.

For additional information, see the following sections:
13.4.1. Heat Exchanger Reporting
13.4.2. Total Heat Rejection Rate

13.4.1. Heat Exchanger Reporting

Reporting the results for the heat exchanger models is done using the **Heat Exchanger Report** dialog box.

Results → Reports → Heat Exchanger **Edit...**

The following variable options are available for reporting:

- **Computed Heat Rejection**
- **Inlet Temperature**
- **Outlet Temperature**
- **Mass Flow Rate**
- **Specific Heat**

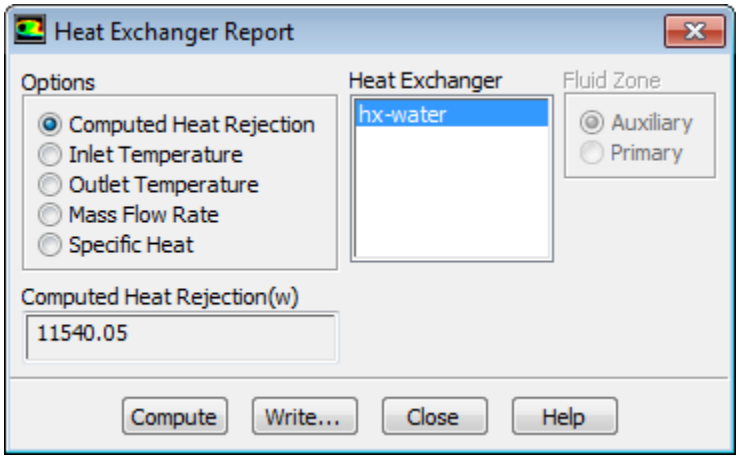
13.4.1.1. Computed Heat Rejection

To display the **Computed Heat Rejection**

1. Select **Computed Heat Rejection** from the **Options** list.
2. Select the **Heat Exchanger** from the selection list.
3. Click **Compute**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.25: The Heat Exchanger Report Dialog Box for Reporting Computed Heat Rejection

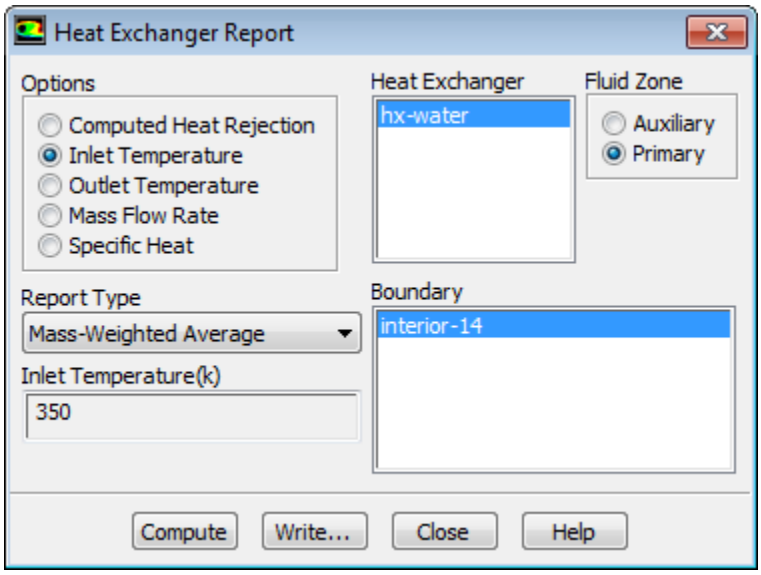


You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

13.4.1.2. Inlet/Outlet Temperature

Inlet/Outlet Temperature can be reported for both primary and auxiliary fluid in the **Heat Exchanger Report** dialog box.

Figure 13.26: The Heat Exchanger Report Dialog Box for Reporting the Inlet Temperature



1. Select **Inlet Temperature** or **Outlet Temperature** from the **Options** list.
2. Select the heat exchanger from the **Heat Exchanger** selection list.
3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select the appropriate boundary zone and report type from the **Boundary** and **Report Type** lists, respectively.

> **Important**
>
> Note that the macro heat exchangers (unlike the dual cell heat exchanger) do not contain an auxiliary cell zone. Hence, the **Boundary** and **Report Type** fields will not appear in the dialog box if you are reporting an auxiliary inlet/outlet temperature.

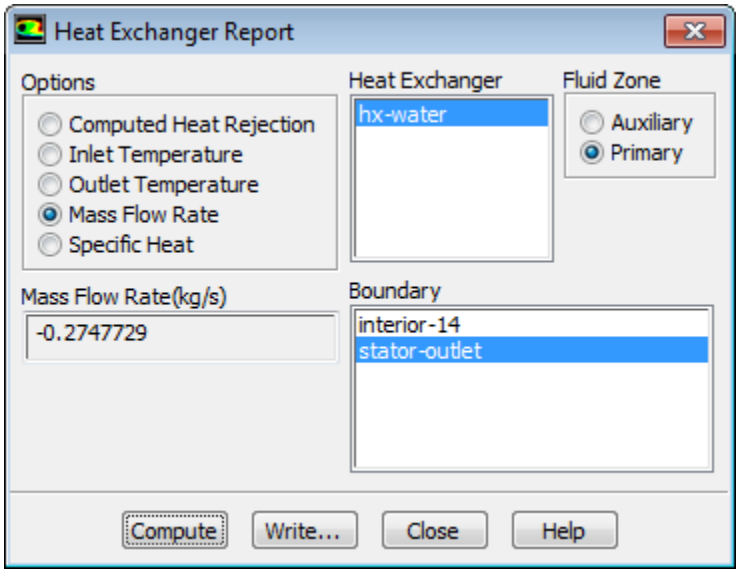
5. Click **Compute**.

You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

13.4.1.3. Mass Flow Rate

Mass Flow Rate can be reported for both the primary and auxiliary fluid in the **Heat Exchanger Report** dialog box.

Figure 13.27: The Heat Exchanger Report Dialog Box for Reporting Mass Flow Rate



1. Select **Mass Flow Rate** from the **Options** group box.

2. Select the heat exchanger from the **Heat Exchanger** selection list.

3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.

4. Select the appropriate boundary zone and report type from the **Boundary** and **Report Type** lists, respectively.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Click **Compute**.

Important

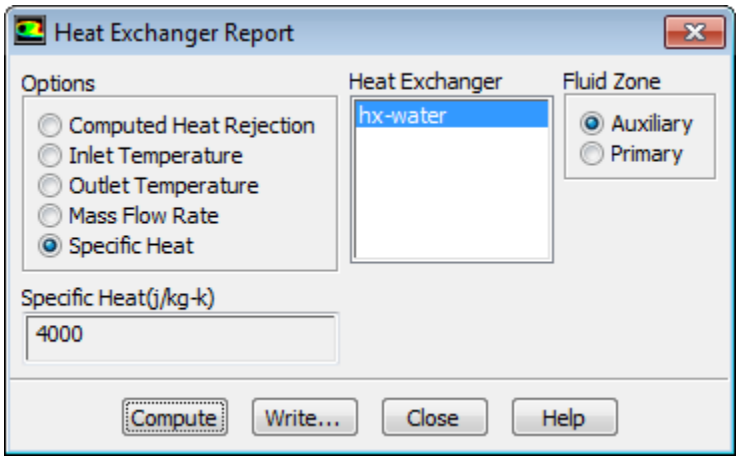
Note that the macro heat exchangers (unlike the dual cell heat exchanger) do not contain an auxiliary cell zone. Hence, the **Boundary** field will not appear in the dialog box if you are reporting an auxiliary fluid mass flow rate.

You can write the computed data to a file by clicking the **Write...** button and entering the name of the heat exchanger report file in the **Select File** dialog box.

13.4.1.4. Specific Heat

Specific Heat for the primary or auxiliary fluid can be reported through the **Heat Exchanger Report** dialog box. If specific heat is defined as a function of temperature, the specific heat reported will be a cell volume averaged value.

Figure 13.28: The Heat Exchanger Report Dialog Box for Reporting Specific Heat



1. Select **Specific Heat** from the **Options** group box.
2. Select the heat exchanger from the **Heat Exchanger** selection list.
3. Select either **Auxiliary** or **Primary** as the **Fluid Zone**.
4. Click **Compute**.

13.4.2. Total Heat Rejection Rate

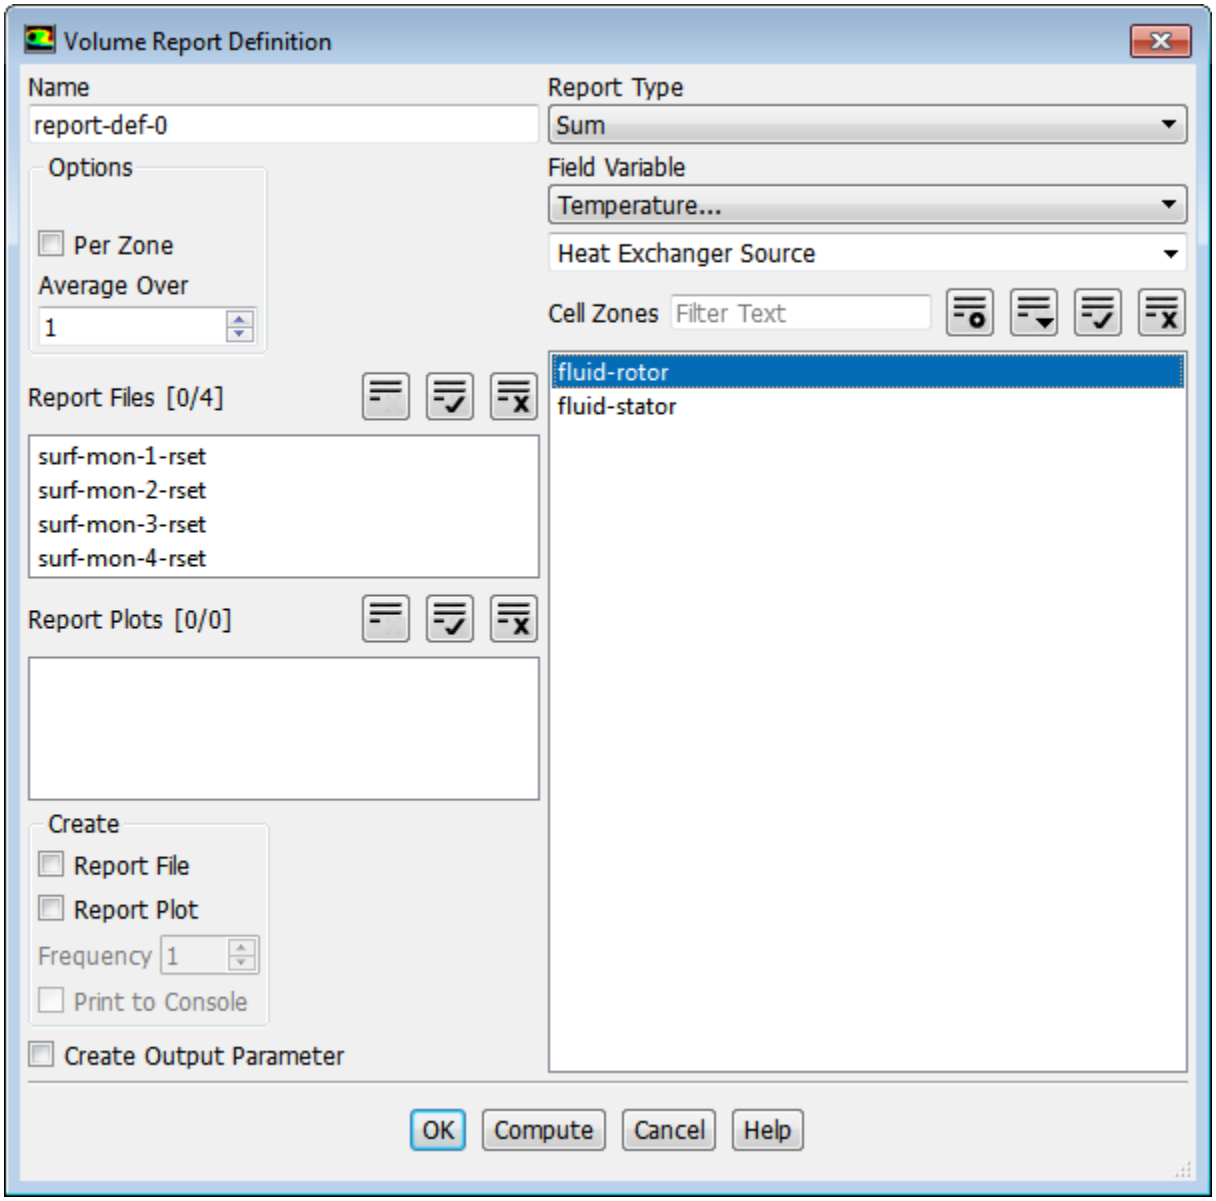
To postprocess the total heat rejection rate, you can set up a volume report definition to monitor convergence and view the computed values.

Solving → Reports → Definitions → New → Volume Report → Sum...

1. Select **Temperature** and **Heat Exchanger Source** from the **Field Variables** drop-down lists.
2. Select the appropriate **Cell Zones** and click **OK** to close the **Volume Monitor** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 13.29: The Volume Report Definition Dialog Box



Important

Note that the macro heat exchangers contain only the primary fluid as the cell zone, but in case of the dual cell model, you can select either the primary or auxiliary fluid.

13.5. Useful Reporting TUI Commands

To report the results for the macro heat exchangers, you can use the following text command:

`define` → `models` → `heat-exchanger` → `macro-model` → `heat-exchanger-macro-report`

Specify the fluid zone *id / name* for which you want to obtain information.

To view the connectivity of the heat exchanger groups, use the text command:

```
(report-connectivity)
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 14: Modeling Species Transport and Finite-Rate Chemistry

ANSYS Fluent can model the mixing and transport of chemical species by solving conservation equations describing convection, diffusion, and reaction sources for each component species. Multiple simultaneous chemical reactions can be modeled, with reactions occurring in the bulk phase (volumetric reactions) and/or on wall or particle surfaces, and in the porous region. Species transport modeling capabilities, both with and without reactions, and the inputs you provide when using the model are described in this chapter. For theoretical information about species transport, see Species Transport and Finite-Rate Chemistry in the Theory Guide.

Note that you may also want to consider modeling your turbulent reacting flame using the mixture fraction approach (for non-premixed systems, described in Modeling Non-Premixed Combustion (p. 1025)), the reaction progress variable approach (for premixed systems, described in Modeling Premixed Combustion (p. 1089)), the partially premixed approach (described in Modeling Partially Premixed Combustion (p. 1099)), or the composition PDF Transport approach (described in Modeling a Composition PDF Transport Problem (p. 1113)). Modeling multiphase species transport and finite-rate chemistry can be found in Modeling Multiphase Flows (p. 1365).

For simulations using ANSYS Fluent reacting flow models, you can specify mixtures consisting of up to 700 chemical species.

The following models and features may not be used with more than 50 species:

- Density-based solver
- Eulerian PDF Transport model
- Melting/solidification model
- Crevice model
- Thermal diffusivity model
- Surface species
- Site species

Information is divided into the following sections:

14.1. Volumetric Reactions
14.2. Wall Surface Reactions and Chemical Vapor Deposition
14.3. Particle Surface Reactions
14.4. Electrochemical Reactions
14.5. Species Transport Without Reactions
14.6. Reacting Channel Model
14.7. Reactor Network Model

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1. Volumetric Reactions

Information about using species transport and finite-rate chemistry as related to volumetric reactions is presented in the following subsections. For more information about the theoretical background of volumetric reactions, see Volumetric Reactions in the Theory Guide.

14.1.1. Overview of User Inputs for Modeling Species Transport and Reactions
14.1.2. Enabling Species Transport and Reactions and Choosing the Mixture Material
14.1.3. Importing a Volumetric Kinetic Mechanism in CHEMKIN Format
14.1.4. Defining Properties for the Mixture and Its Constituent Species
14.1.5. Setting up Coal Simulations with the Coal Calculator Dialog Box
14.1.6. Defining Cell Zone and Boundary Conditions for Species
14.1.7. Defining Other Sources of Chemical Species
14.1.8. Solution Procedures for Chemical Mixing and Finite-Rate Chemistry
14.1.9. Postprocessing for Species Calculations

14.1.1. Overview of User Inputs for Modeling Species Transport and Reactions

The basic steps for setting up a problem involving species transport and reactions are listed below.

1. Select species transport and volumetric reactions, and specify the mixture material. See Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960). The mixture material concept is explained in Mixture Materials (p. 959).

2. If you are also modeling wall or particle surface reactions, select wall surface and/or particle surface reactions. See Wall Surface Reactions and Chemical Vapor Deposition (p. 995) Particle Surface Reactions (p. 1001) for details.

3. Check and/or define the properties of the mixture. See Defining Properties for the Mixture and Its Constituent Species (p. 972). Mixture properties include the following:

   - species in the mixture
   - reactions
   - other physical properties (for example, viscosity, specific heat)

4. Check and/or set the properties of the individual species in the mixture. See Defining Properties for the Mixture and Its Constituent Species (p. 972).

5. Set species cell zone and boundary conditions. See Defining Cell Zone and Boundary Conditions for Species (p. 990).

In many cases, you will not need to modify any physical properties of mixture material because the solver gets species properties, reactions, and so on, from the materials database when you choose the mixture material. Some properties, however, may not be defined in the database. You will be warned when you choose your material if any required properties need to be set, and you can then assign appropriate values for these properties. You may also want to check the database values of other properties to be sure that they are correct for your particular application. For details about modifying an existing mixture material or creating a new one from nothing, see Defining Properties for the Mixture and Its Constituent Species (p. 972). Modifications to the mixture material can include the following:

- Addition or removal of species
- Changing the chemical reactions

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Modifying other material properties for the mixture
- Modifying material properties for the mixture's constituent species

If you are solving a reacting flow, you will usually want to define the mixture's specific heat as a function of composition, and the specific heat of each species as a function of temperature. You may want to do the same for other properties as well. By default, most species specific heats in the database are piecewise-polynomial functions of temperature, but you may choose to specify a different temperature-dependent function if you know of one that is more suitable for your problem.

14.1.1.1. Mixture Materials

The concept of mixture materials has been implemented in ANSYS Fluent to facilitate the setup of species transport and reacting flow. A mixture material may be thought of as a set of species and a list of rules governing their interaction. The mixture material carries with it the following information:

- A list of the constituent species, referred to as "fluid" materials
- A list of mixing laws dictating how mixture properties (density, viscosity, specific heat, and so on) are to be derived from the properties of individual species if composition-dependent properties are desired
- A direct specification of mixture properties if composition-independent properties are desired
- Diffusion coefficients for individual species in the mixture
- Other material properties (for example, absorption and scattering coefficients) that are not associated with individual species
- A set of reactions, including a reaction type (finite-rate, eddy-dissipation, and so on) and stoichiometry and rate constants

The mixture materials are stored in the ANSYS Fluent materials database. Many common mixture materials are included (for example, methane-air, propane-air). Generally, one or two-step reaction mechanisms and many physical properties of the mixture and its constituent species are defined in the database.

The ANSYS Fluent materials database is accessed in one of two ways, depending on the sequence of your workflow:

- through the **Species Model** dialog box before any one of the species models is enabled
- through the **Create/Edit Materials** dialog box after one of the available species models is enabled

When you enable one of the species models, the mixture material that you have selected for your application, its constituent fluid materials, and properties will be loaded into your simulation. If any necessary information about the selected material (or the constituent fluid materials) is missing, the solver will inform you that you need to specify it. In addition, you may choose to modify any of the predefined properties. See Using the **Create/Edit Materials** Dialog Box (p. 461) for information about the sources of ANSYS Fluent database property data.

For example, if you plan to model combustion of a methane-air mixture using global kinetics, you do not need to explicitly specify the species involved in the reaction or the reaction itself. You will simply select **methane-air** as the mixture material to be used, and the relevant species (CH_4, O_2, CO_2, H_2O, and N_2) and reaction data will be loaded into the solver from the database. You can then check the species, reactions, and other properties and define any properties that are missing and/or modify any properties for which you want to use different values or functions. You will generally want to define a composition-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and temperature-dependent specific heat, and you may want to define additional properties as functions of temperature and/or composition.

The use of mixture materials gives you the flexibility to select and load from the Fluent database one of the many predefined mixtures that is appropriate for your case or, if you want to create your own custom mixture material, a mixture-template (the default) consisting of H_2O, O_2, and N_2. Once the mixture material has been copied to the solver, you can modify it in the Create/Edit Materials Dialog Box (p. 2302), as described in Defining Properties for the Mixture and Its Constituent Species (p. 972).

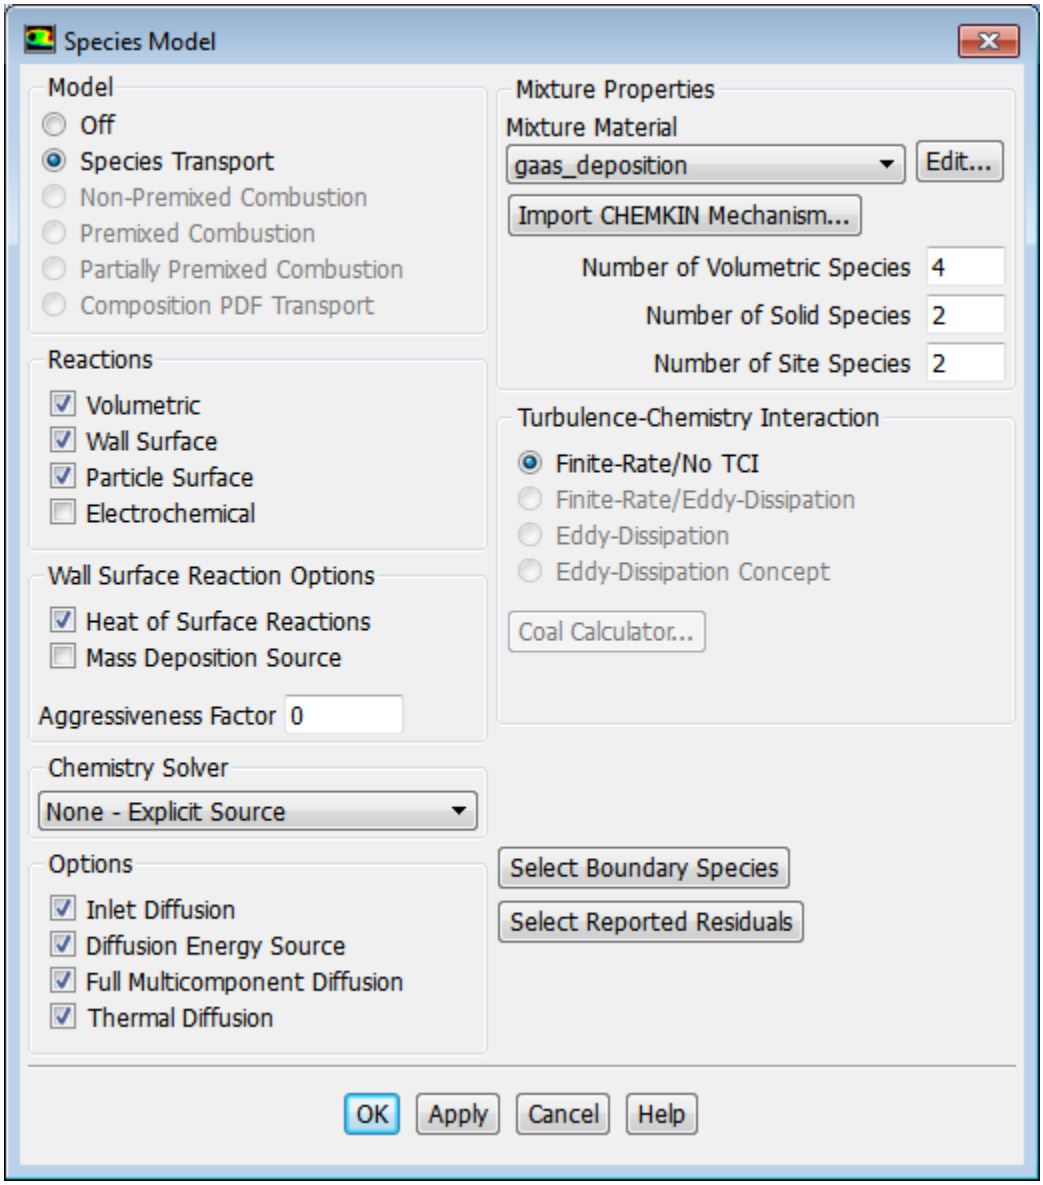
14.1.2. Enabling Species Transport and Reactions and Choosing the Mixture Material

The problem setup for species transport and volumetric reactions begins in the **Species Model** dialog box (Figure 14.1: The Species Model Dialog Box (p. 961)). For cases that involve multiphase species transport and reactions, refer to Modeling Species Transport in Multiphase Flows in the Theory Guide.

Setup → **Models** → **Species** **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.1: The Species Model Dialog Box



1. Under **Model**, select **Species Transport**.

2. Under **Reactions**, select **Volumetric**.

3. In the **Mixture Material** drop-down list under **Mixture Properties**, select which mixture material you want to use in your problem or, if you want to create your own mixture material, retain the default selection of **mixture-template** consisting of H_2O, O_2, and N_2. The drop-down list includes all of the mixtures that are currently defined in the database. If there is a mixture material listed that is similar to your desired mixture, you may choose that material and modify it following the steps provided in Defining Properties for the Mixture and Its Constituent Species (p. 972).

   The number of species in the selected mixture material is displayed in the **Number of Volumetric Species** field and, if applicable, in the **Number of Solid Species** and **Number of Site Species** fields. To review the mixture composition and reactions of the selected Fluent database mixture material, click the **View...** button to the right of **Mixture Material**. This opens the **Fluent Database Materials** dialog box. Clicking, in turn, the **View...** buttons next to **Mixture Species** and **Reaction** opens the corresponding dialog boxes allowing you to examine the constituent species and reactions data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note, that the mixture properties cannot be edited before the mixture material is copied to your Fluent problem. For this reason, all related controls are dimmed while viewing the mixture properties.

When you enable the species transport model by clicking either **OK** or **Apply**, ANSYS Fluent performs the following:

- The selected Fluent database mixture material including all constituent fluid materials (species) and properties are automatically copied to your case and appear under **Mixture** in the tree and the **Materials** task page.
- If any properties for the selected mixture material (or the constituent fluid materials) are missing, the solver prints to the console a notice of the required data.
- When the mixture material is copied, the **Mixture Material** drop-down list in the **Species Model** dialog box changes to contain only the mixtures defined for your Fluent problem.
- The **View...** button is replaced by the **Edit...** button giving you an option to access the **Edit Material** dialog box (Edit Material Dialog Box (p. 2355)) from the **Species Model** dialog box.
- The **Create/Edit Materials** dialog box lists **mixture** in the **Material Type** drop-down list allowing you to access the Fluent mixture material database. If you want to check or modify any properties of the mixture material, use the Create/Edit Materials Dialog Box (p. 2302), as described in Defining Properties for the Mixture and Its Constituent Species (p. 972).

You can add more mixture materials to your case by copying them from the database, as described in Copying Materials from the ANSYS Fluent Database (p. 464), or by creating a new mixture, as described in Creating a New Material (p. 466) and Defining Properties for the Mixture and Its Constituent Species (p. 972).

4. Select the **Turbulence-Chemistry Interaction** (TCI) modeling option. The following options are available:

Finite-Rate/No TCI

computes only the Arrhenius rate (see Equation 7.7 in the Theory Guide) and neglects turbulence-chemistry interaction. This model is recommended for laminar or turbulent flows using complex chemistry where either the turbulence time-scales are expected to be fast relative to the chemistry time scales or where the chemistry is sufficiently complex that the chemistry timescales of importance are highly disparate throughout the simulation. You can specify the following inputs:

Flow Iterations per Chemistry Update (steady-state only)

Increasing the number reduces the computational expense of the chemistry calculations. By default, ANSYS Fluent will update the chemistry once per flow iteration. This option is not available when the **None - Explicit Source** option is selected for **Chemistry Solver**.

Aggressiveness Factor (steady-state only)

This is a numerical factor that controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5. This option is not available when the **None - Explicit Source** option is selected for **Chemistry Solver**.

Finite-Rate/Eddy-Dissipation (turbulent flows only)

computes both the Arrhenius rate and the mixing rate and uses the smaller of the two.

Eddy-Dissipation (turbulent flows only)

computes only the mixing rate (see Equation 7.25 and Equation 7.26 in the Theory Guide).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eddy-Dissipation Concept (turbulent flows only)
models turbulence-chemistry interaction with detailed chemical mechanisms (see Equation 7.7 and Equation 7.30 in the Theory Guide). When using this model, you can modify the following:

Flow Iterations per Chemistry Update (steady-state only)
Increasing the number reduces the computational expense of the chemistry calculations. By default, ANSYS Fluent will update the chemistry once per flow iteration.

Aggressiveness Factor (steady-state only)
This is a numerical factor that controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5.

Volume Fraction Constant , Time Scale Constant
C_ξ in Equation 7.28 and C_τ in Equation 7.29 in the Theory Guide. The default values are recommended.

5. From the **Chemistry Solver** drop-down list, select the solver for your simulation (note that the solvers available in the drop-down list are dependant on the selected **Turbulence-Chemistry Interaction** model):

   - If you want the stiff chemistry to relax to chemical equilibrium without solving reactions, select **Relax to Chemical Equilibrium**. This option is not available for **Eddy Dissipation Concept**. For information about the Relaxation to Chemical Equilibrium model, refer to The Relaxation to Chemical Equilibrium Model in the Theory Guide

   Important

   The **Relax to Chemical Equilibrium** chemistry solver requires thermodynamic data of all species to calculate chemical equilibrium. You can supply your own database using the **CHEMKIN Mechanism Import** dialog box (opened by clicking **Import CHEMKIN mechanism...**) (see Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967) and Importing a Surface Kinetic Mechanism in CHEMKIN Format (p. 995) for details). A sample database is also contained in the file `.../flu-entx.x/cpropep/data/thermo.db`. If you define your own species in ANSYS Fluent, as determined by the **Chemical Formula** in the **Create/Edit Materials** dialog box, and this species name is not in the thermo.db file, ANSYS Fluent will report an error. To overcome this error, you must manually enter all the unknown species in the thermo file.

   - If you want to solve finite-rate chemistry, select either **Stiff Chemistry Solver** or **CHEMKIN-CFD Solver**. These two solvers are available when using the **Finite-Rate/No TCI** or **Eddy-Dissipation Concept** TCI option.

     Selecting **CHEMKIN-CFD Solver** will enable you to use the ANSYS CHEMKIN-CFD solution algorithms, which are based on and compatible with the ANSYS Chemkin-Pro technology. Once you click **OK** or **Apply**, you will be prompted to import a CHEMKIN mechanism, if you have not already done so. Refer to the ANSYS Chemkin-Pro Input and Theory manuals on the ANSYS Customer Portal (support.ansys.com/docdownloads) for details on the chemistry formulation options. See Using ANSYS Encrypted Mechanisms (p. 968) for instructions on establishing a CHEMKIN-mechanism based material. In addition, Appendix D: Controlling CHEMKIN-CFD Solver Parameters Using Text Commands (p. 2875) includes information about advanced solver settings and diagnostic information for the CHEMKIN-CFD solver.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want to make explicit use of chemistry source terms in the species transport equations, without a stiff-chemistry solver, select **None - Explicit Source**. This default solver is not recommended for stiff or complex chemistry.

6. (optional) For TCI model options that consider finite-rate chemistry, set the integration parameters using the **Integration Parameters** dialog box (opened by clicking the **Integration Parameters...** button). In the **Integration Parameters** dialog box, you can select acceleration methods (see Using Chemistry Acceleration (p. 1127) for more details):

   - **Dynamic Mechanism Reduction** (DMR) (for **Stiff Chemistry Solver**). See Using Dynamic Mechanism Reduction (p. 1131) for details.
   - **Chemistry Agglomeration** (CA) (for **Stiff Chemistry Solver** and **Relax to Chemical Equilibrium**). See Using Chemistry Agglomeration (p. 1136) for details.
   - **ISAT**. See Using ISAT (p. 1128) for details.
   - **Dynamic Cell Clustering** (DCC) (for the **CHEMKIN-CFD Solver** in transient cases). DCC is enabled by default. See see Using Dynamic Cell Clustering (p. 1137) for details.

7. (optional) Select any **Options** desired. If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, select the **Full Multicomponent Diffusion** or **Thermal Diffusion** option, respectively.

   See Full Multicomponent Diffusion (p. 520) for details.

8. Enable the **Thickened Flame Model** when modeling unsteady laminar flames, or when using an LES model for turbulent premixed and partially-premixed flames. Specify the **Number of Grid Points in Flame**, which by default are 8 grid points. Consequently, in the **Create/Edit Materials** dialog box, you will specify the **Laminar Flame Speed**, for which you have a choice of **constant**, **user-defined**, or **metghalchi-keck-law**, and the **Laminar Flame Thickness**, for which you have a choice of **constant**, **user-defined**, or **diffusivity-over-flame-speed**.

   Note

   Since the thickened flame model must capture the correct flame speed, it is imperative that the combination of your chemical mechanism and your molecular transport properties (diffusion coefficients and thermal conductivity) reproduce the correct laminar flame speed. It is recommended that you verify this with a 1D premixed flame simulation using ANSYS Chemkin-Pro, for example.

   When the **Thickened Flame Model** is enabled (Figure 14.2: The Species Model Dialog Box Displaying the Thickened Flame Model (p. 965)), you have the option to hook a UDF in the **User-Defined Function Hooks** dialog box to customize the **Thickened Flame Model** parameters. Refer to `DEFINE_THICKENED_FLAME_MODEL` in the *Fluent Customization Manual* for details.

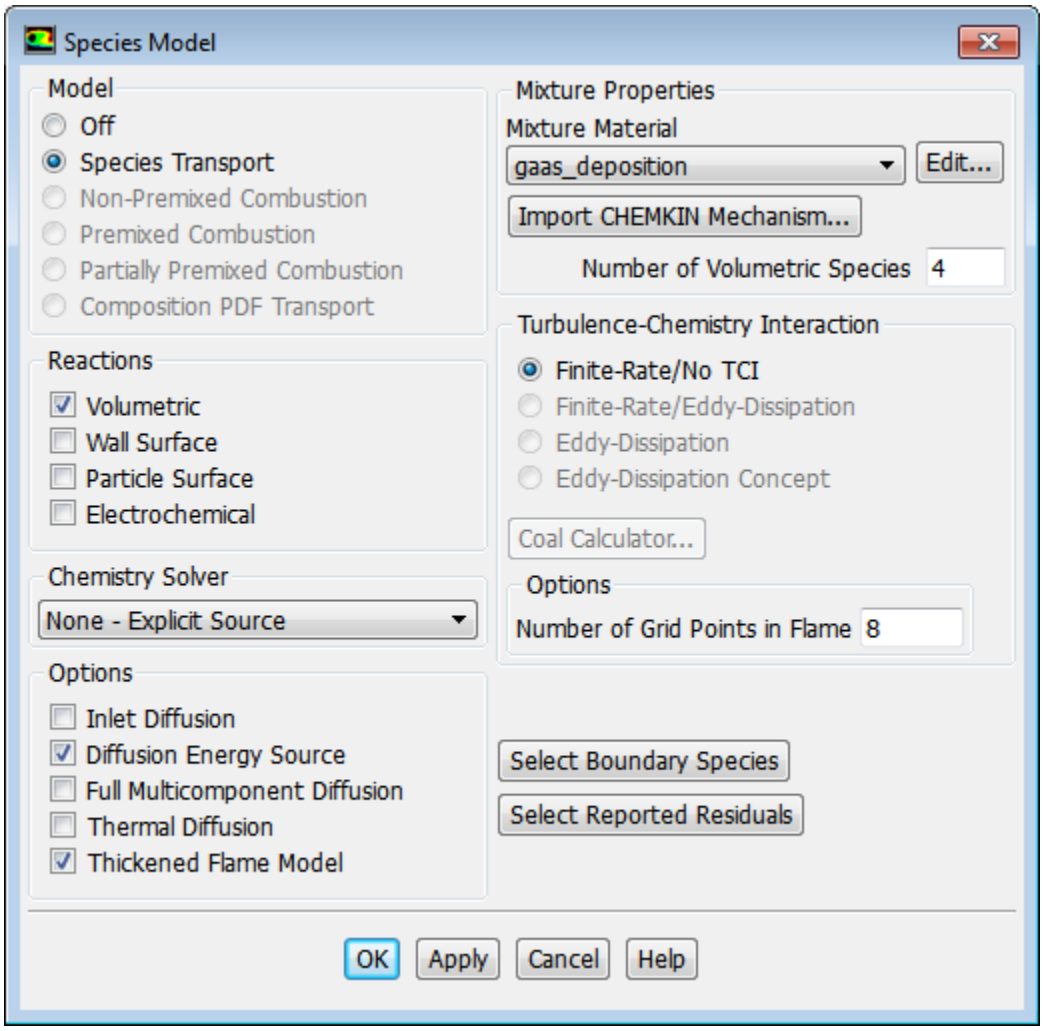
   Important

   The **Thickened Flame Model** is available only for unsteady laminar or turbulent (LES / DES / SAS / SBES / SDES) flows, with **Species Transport** and **Volumetric Reactions** enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For information about the theory behind the **Thickened Flame Model**, refer to The Thickened Flame Model in the Theory Guide.

Figure 14.2: The Species Model Dialog Box Displaying the Thickened Flame Model



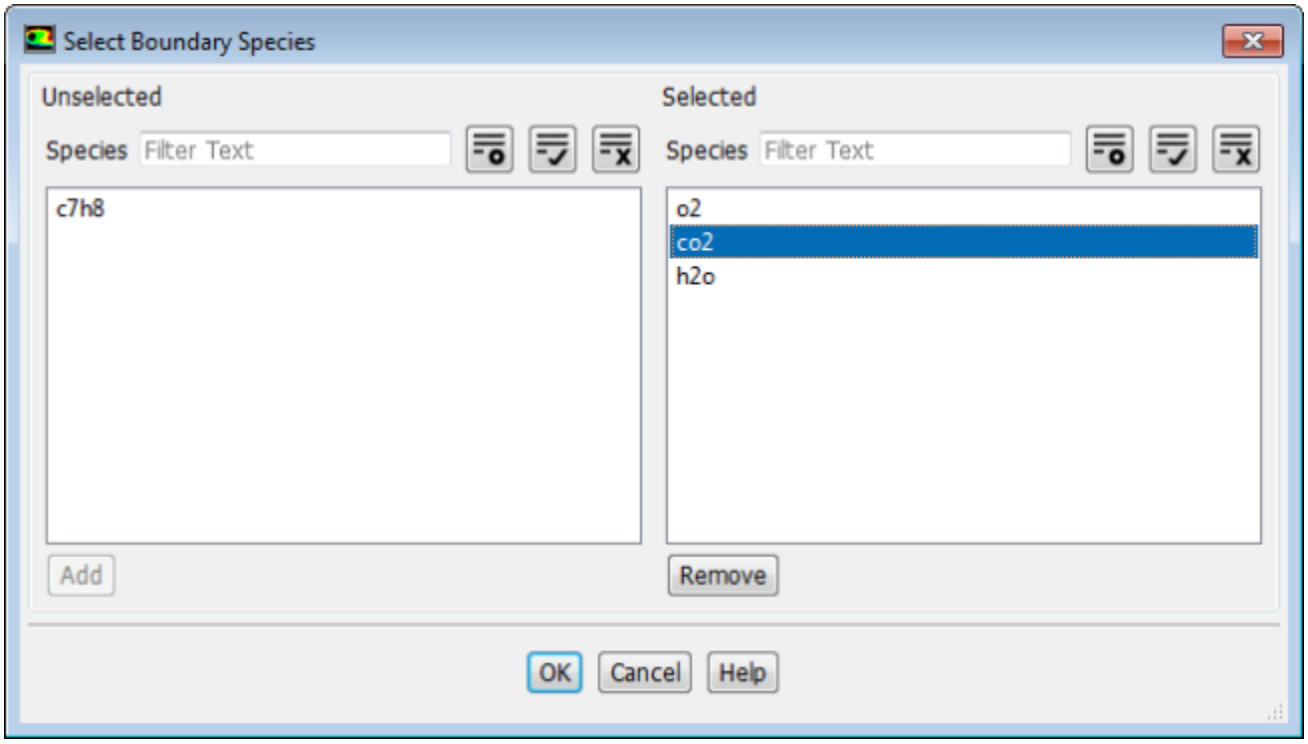
The Species Model Dialog Box

9. (optional) Select the species for which you want to specify boundary conditions. Only the species that you have selected will be listed in the relevant boundary condition dialog boxes. This will facilitate the problem setup, especially when a large number of species are used in a gas mixture. Note that the **Patch** and **Hybrid Initialization** dialog boxes, as well as the **Solution Initialization** task page will also display only the selected species.

   a. Click **Select Boundary Species**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.3: The Select Boundary Species Dialog Box



By default, all the gas species for which the transport equations are to be applied are set as boundary species and appear in the **Selected** multiple-selection list of the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)).

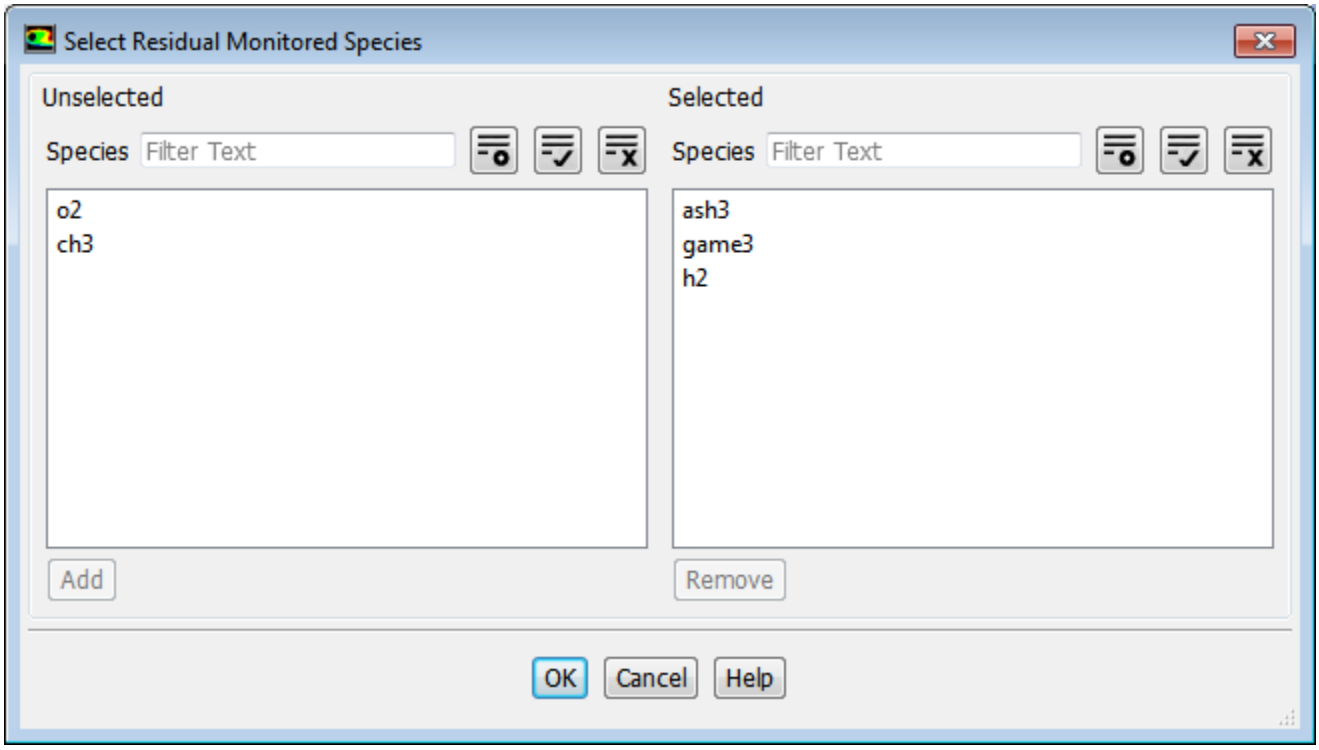
b. Modify the boundary species list as follows:

- To remove the species from the **Selected Species** multiple-selection list, select it and click **Remove**. The species will be moved from the **Selected Species** list to the **Unselected Species** list.
- To add the species back to the **Selected Species** list, simply select it in the **Unselected Species** multiple-selection list and click **Add**. The species will be moved from the **Unselected Species** list to the **Selected Species** list.

10. (optional) In a similar manner, click the **Select Reported Residuals** button and select the species that you want to monitor. Only the residuals for the selected species will be monitored and plotted in the graphics window during the simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.4: The Select Residual Monitored Species



By default, all the species for which the species transport equations are to be solved are set as monitored species, and their residual plots will be drawn in the graphics window during the run. For a large number of monitored species, it may be difficult to distinguish the overlapping plot lines. By decreasing the number of monitored species, you can obtain clearer residual plots.

Important

- The Fluent solver performs the convergence checks only for the monitored species. To prevent false convergence, make sure to include the species that may have difficulties converging in the monitored species list.
- You can modify the list of the monitored species dynamically during a run.

14.1.3. Importing a Volumetric Kinetic Mechanism in CHEMKIN Format

You can import gas kinetics mechanism in CHEMKIN format, which can be used with any solver option. For the **CHEMKIN-CFD Solver** and **Stiff Chemistry Solver**, native CHEMKIN computations will determine reaction rates, so full compatibility with ANSYS Chemkin-Pro is provided.

Note

If a mechanism includes at least one reaction type that is not supported in the Fluent material-definition interface (that is, it is not included in the options for manual setup of reactions), the reactions of the CHEMKIN mechanism will not be displayed in the Fluent interface, even though they will be correctly used in Fluent computations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.3.1. Using ANSYS Encrypted Mechanisms

For certain types of simulations, Fluent supports the use of encrypted gas kinetics mechanisms, such as those derived from the ANSYS Model Fuels Library (encrypted) or through ANSYS services. In order to use an encrypted mechanism, you must first import both the gas-phase kinetics and thermodynamic files as described in Procedure for Importing Volumetric CHEMKIN Mechanisms (p. 968).

When using encrypted CHEMKIN gas mechanisms, note the following points:

- Encrypted mechanisms can only be used with the CHEMKIN-CFD solver, the stiff chemistry solver, or the **Relax to Chemical Equilibrium** option
- Prior to importing a flamelet or reading a PDF table generated with an encrypted mechanism, you must first import the mechanism
- Chemical equilibrium PDF table generation is not supported
- Multiphase and Decoupled Detailed Chemistry models are not supported
- You cannot combine encrypted and plain-text gas kinetics, surface kinetics and thermodynamics files in a simulation
- The chemistry acceleration options Dynamic Mechanism Reduction (DMR) and Dimension Reduction (DR) are not supported.

Note

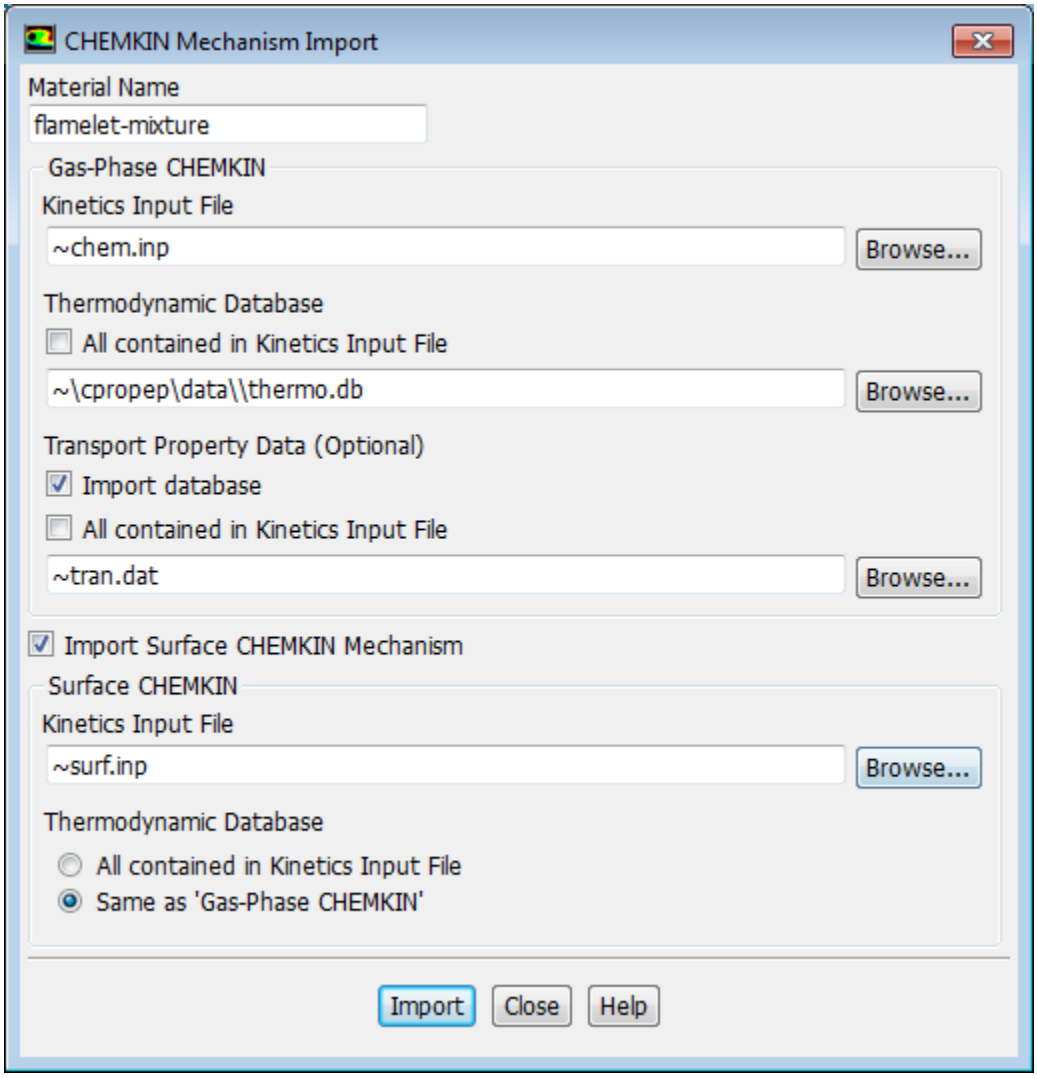
The proprietary reaction data will not be displayed in the Fluent interface.

14.1.3.2. Procedure for Importing Volumetric CHEMKIN Mechanisms

You can import the CHEMKIN mechanism file into ANSYS Fluent using the **CHEMKIN Mechanism Import** dialog box (Figure 14.5: The CHEMKIN Mechanism Import Dialog Box for Volumetric Kinetics (p. 969)) (opened by clicking **Import CHEMKIN Mechanism...** in the **Species Model** dialog box).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.5: The CHEMKIN Mechanism Import Dialog Box for Volumetric Kinetics



In the **CHEMKIN Mechanism Import** dialog box

1. Enter a name for the chemical mechanism under **Material Name**.

2. Enter the path to the CHEMKIN file (for example, *path/file*.inp) in the **Kinetics Input File** text field in the **Gas-Phase CHEMKIN** group box.

   Important

   Since ANSYS Fluent does not solve for the last species, you must ensure that the last species in the CHEMKIN mechanism species list is an abundant species, such as nitrogen. If not, edit the CHEMKIN mechanism file before importing it into ANSYS Fluent, and move the most abundant species (that is the species in your system with the largest total mass fraction) to the end of the species list.

3. Specify species thermodynamic property data. You can include the data in the kinetics input file and/or in a separate file as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want to specify thermodynamic data for all species in the kinetics input file, enable **All contained in Kinetics Input File** to avoid the need to specify a separate file.
- If you provide some or all species thermodynamic data in a separate file, disable **All contained in Kinetics Input File** and specify the thermodynamic data file location.

You can either use the default thermodynamic database file, `thermo.db`, provided in the `cpropep\data` directory in your ANSYS Fluent installation area or specify the path of your thermodynamic database file if `thermo.db` does not contain all the gas-phase species in the CHEMKIN mechanism. The format for `thermo.db` is detailed in the CHEMKIN manual [52] (p. 2889).

4. (Optional). To import transport property data, enable **Import database** under **Transport Property Data (Optional)** and specify the location of the species transport property data. You can include the data in the kinetics input file and/or in a separate file as follows:

   - If you want to specify transport property data for all species in the kinetics input file, enable **All contained in Kinetics Input File**, to avoid the need to specify a separate file.
   - If you want to provide some or all species transport data in a separate file, disable **All contained in Kinetics Input File** and specify the transport property data file location.

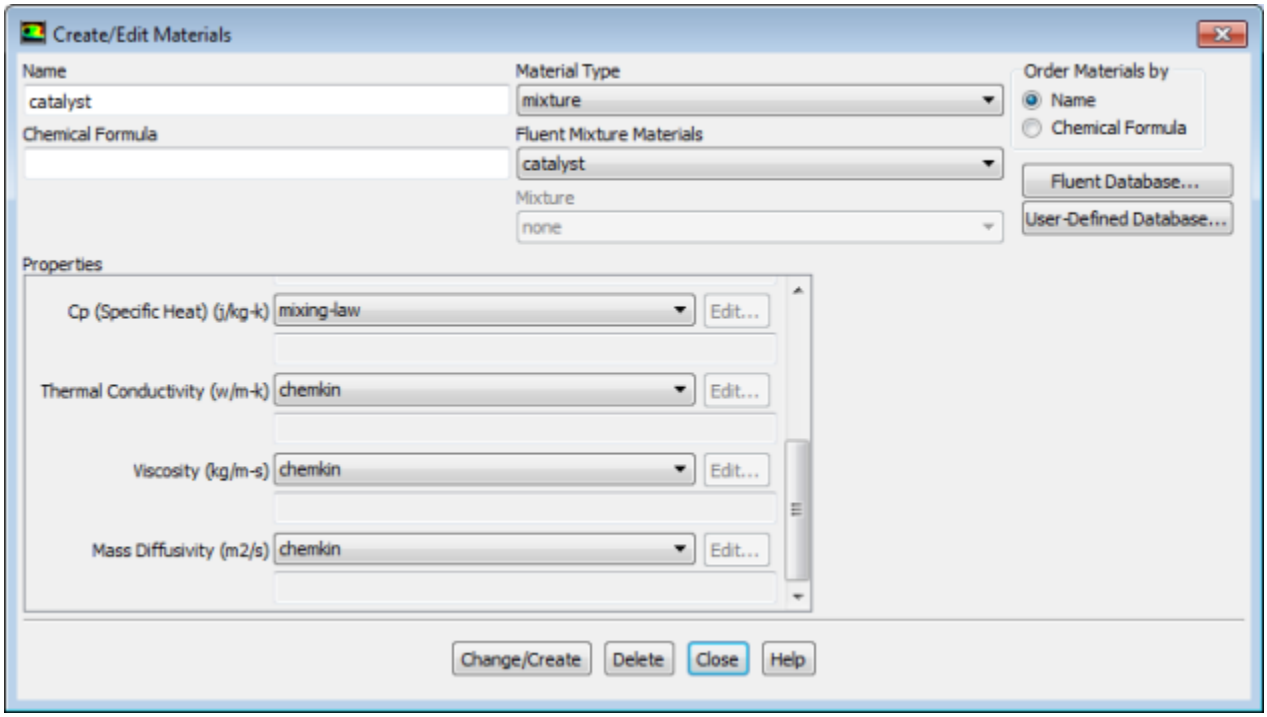
   ANSYS Fluent will enable mixture-averaged multicomponent diffusion and set the Lennard-Jones kinetic theory parameters for all the species in the imported CHEMKIN mechanism. If you would like to use Stefan-Maxwell diffusion, enable the **Full Multicomponent Diffusion** in the **Species** dialog box.

   If you want to use native CHEMKIN transport property calculations, you must first select **CHEMKIN-CFD Solver** from the **Chemistry Solver** drop-down list in the **Species** dialog box (Figure 14.1: The Species Model Dialog Box (p. 961)). Once a file with CHEMKIN transport properties is read, ANSYS Fluent will create a material with the specified name, which will contain the data for the species and reactions, and add it to the list of available **Mixture Materials** in the Create/Edit Materials Dialog Box (p. 2302). For material properties such as **Specific Heat**, **Viscosity**, **Thermal Conductivity**, **Mass Diffusivity**, and **Thermal Diffusion**, listed in the **Create/Edit Materials** dialog box, the option **chemkin** will appear in the drop-down list of each of the properties (Figure 14.6: The Material Dialog Box When Importing CHEMKIN Transport Properties (p. 971)), allowing you to use material property values computed by ANSYS Chemkin-Pro.

   Note that when **Full Multicomponent Diffusion** is enabled in the **Species** dialog box, ANSYS Chemkin-Pro returns full multicomponent diffusivities. If **Full Multicomponent Diffusion** is disabled, ANSYS Chemkin-Pro returns mixture averaged mass diffusivities for each species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.6: The Material Dialog Box When Importing CHEMKIN Transport Properties



5. Click the **Import** button.

   Once you click **Import**, ANSYS Fluent automatically saves the reaction mechanism and thermal files in the data structure. The original input files are not required to be retained along with the Fluent case file. ANSYS Fluent will automatically regenerate these files as needed (for example, when using the CHEMKIN-CFD solver).

For information on how to import a surface kinetic mechanism in CHEMKIN format, see Importing a Surface Kinetic Mechanism in CHEMKIN Format (p. 995).

14.1.3.3. CHEMKIN Mechanisms Included with ANSYS Fluent

A CHEMKIN mechanism is a chemical reaction mechanism (also called a chemistry set) that has the following mechanism components:

- A file containing thermochemical data for the chemical species of interest
- A file containing a description of the reactions occurring in the gas phase
- (Optional) A file containing a description of the reactions occurring at the gas-surface interface or on the surface
- (Optional) A file containing gas-phase transport data

A set of gas-phase and/or surface reactions are generally developed using specific thermochemical data. Thus, the gas-phase kinetics, surface kinetics, and thermodynamic data are treated as a chemistry "set" in reacting-flow simulations. ANSYS Fluent provides the following fuel-combustion mechanisms (including reactions, thermodynamic data, and transport data) that are appropriate for use in common combustion simulations:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Methane / Ethane: 50-species version of GRI-Mech 3.0 (`grimech30_50spec`)

  This is the original `GRI-mech` 3.0 (53 species) [109] (p. 2892) with three species (argon AR, propane C3H8, and propyl radical C3H7) and their reactions removed.

  In fuel/air or fuel/oxygen combustion, the removal of these species is expected to have negligible effect on the mechanism predictive capabilities for methane and ethane as fuels. The applicability of the GRI mechanism and validation cases are provided on the GRI mechanism web site [109] (p. 2892).

- Propane: 37-species high-temperature mechanism (`Propane-NOx_highT`)

  The mechanism has 211 elementary reaction steps and was obtained by removing species and reactions that are unimportant for propane combustion from the comprehensive master mechanism [73] (p. 2891). ANSYS Chemkin-Pro Reaction Workbench software was used to reduce the master mechanism under the conditions of slightly lean and high pressure laminar flame of a propane/air mixture using the Directed Relation Graph (DRG) method.

- Two hydrogen mechanisms:

  – 9-species version for H2 combustion (`H2_mech`)

    The mechanism has 21 elementary reaction steps and has been extracted from the Li et al. [57] (p. 2890) mechanism for CO and other hydrocarbons.

  – 21-species version for H2 combustion with NOx (`H2_NOx_mech`)

    The mechanism has 105 elementary reaction steps. The hydrogen combustion sub-mechanism is the same as the `H2_mech` mechanism, above. The NO_x sub-mechanism is based on the study by the Glarborg group [91] (p. 2892).

14.1.4. Defining Properties for the Mixture and Its Constituent Species

As discussed in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958), if you use a mixture material from the ANSYS Fluent database, most mixture and species properties will already be defined. You may follow the procedures in this section to check the current properties, modify some of the properties, or set all properties for a brand-new mixture material that you are defining from nothing.

Remember that you will need to define properties for the mixture material and also for its constituent species. It is important that you define the mixture properties before setting any properties for the constituent species, since the species property inputs may depend on the methods you use to define the properties of the mixture.

The recommended sequence for property inputs is as follows:

1. Define the mixture species, and reaction(s), and define physical properties for the mixture. Remember to click the **Change/Create** button when you are done setting properties for the mixture material.

2. Define physical properties for the species in the mixture. Remember to click the **Change/Create** button after defining the properties for each species.

These steps, all of which are performed in the Create/Edit Materials Dialog Box (p. 2302), are described in detail in this section.

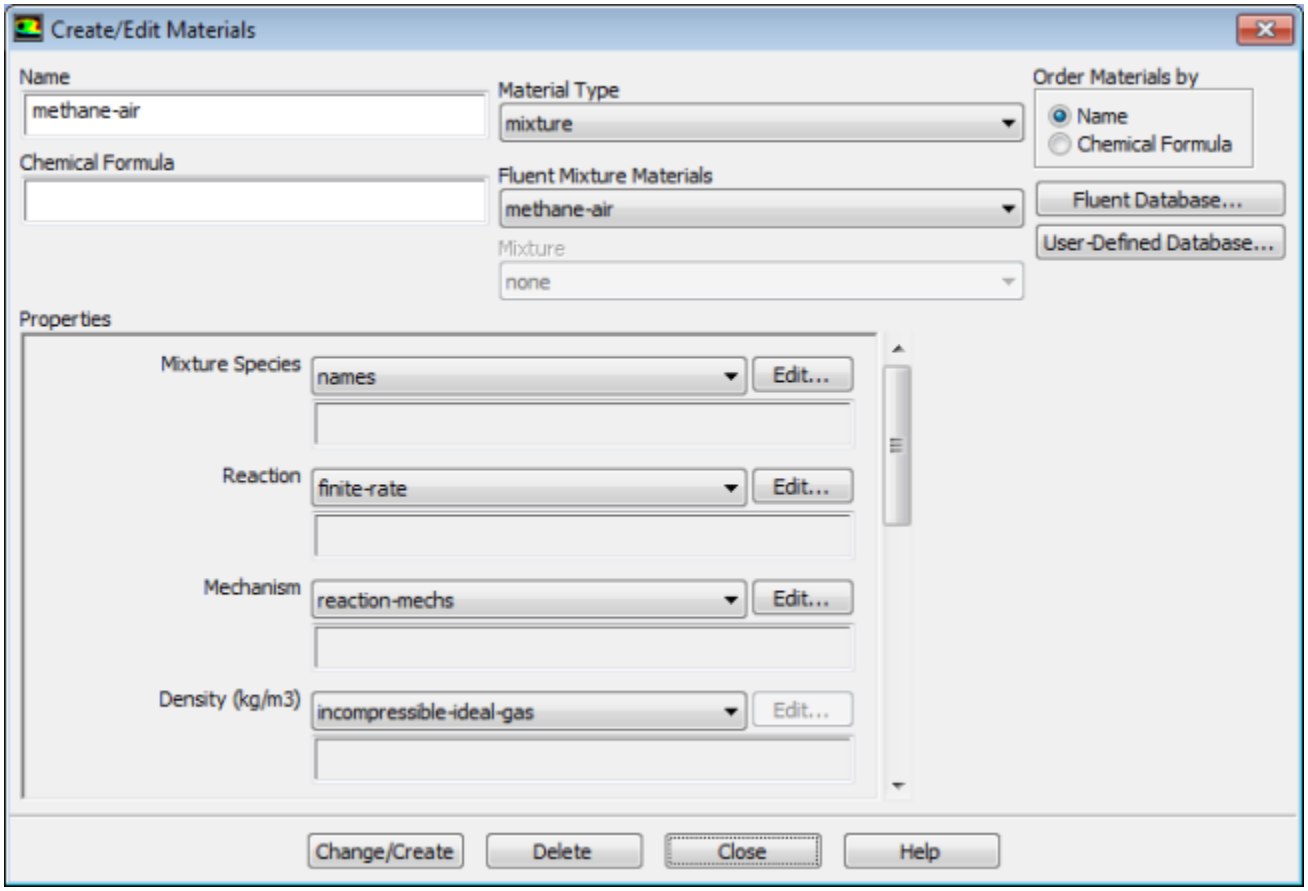
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Materials

14.1.4.1. Defining the Species in the Mixture

In the **Create/Edit Materials** dialog box (Figure 14.7: The Create/Edit Materials Dialog Box (Showing a Mixture Material) (p. 973)), check that the **Material Type** is set to **mixture** and your mixture is selected in the **Fluent Mixture Materials** list.

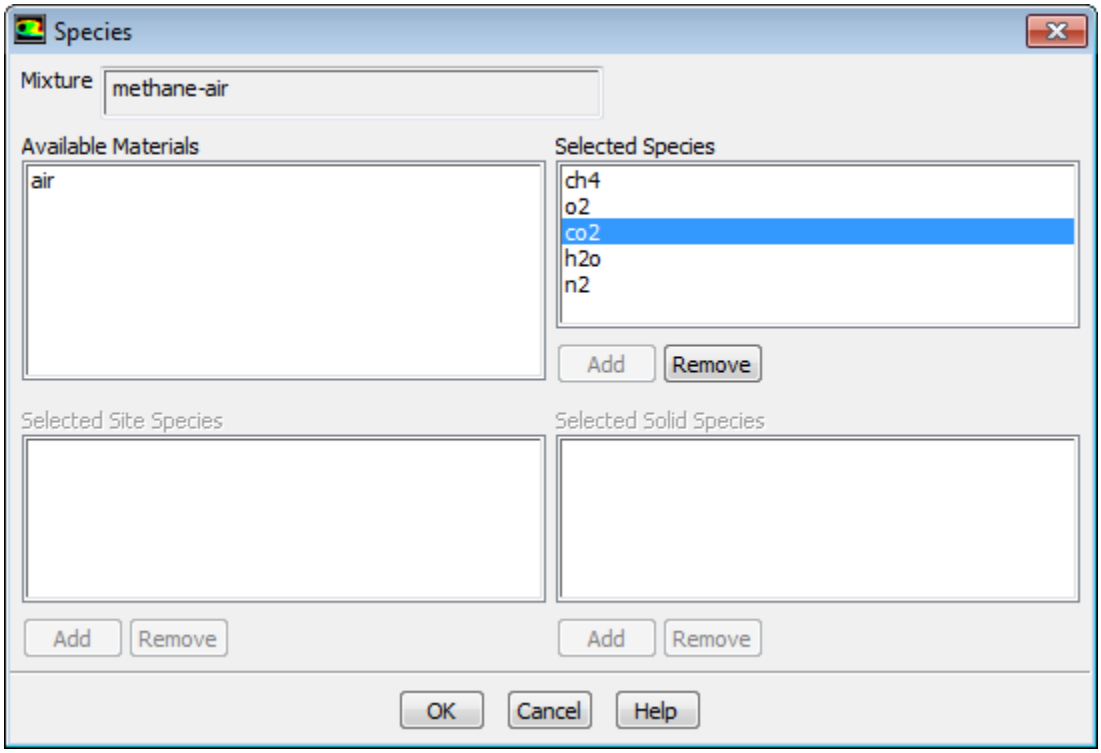
Figure 14.7: The Create/Edit Materials Dialog Box (Showing a Mixture Material)



Click the **Edit...** button to the right of **Mixture Species** under the **Properties** group box and in the Species Dialog Box (p. 2332) (Figure 14.8: The Species Dialog Box (p. 974)) that opens define the species in the mixture material.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.8: The Species Dialog Box



Important

For Chemkin mechanisms, the recommended approach for modifying mixture materials is to modify the Chemkin mechanism file and then re-import it into your Fluent case.

14.1.4.1.1. Overview of the Species Dialog Box

In the **Species** dialog box, the **Selected Species** list shows all of the fluid-phase species in the mixture. If you are modeling wall or particle surface reactions, the **Selected Solid Species** list will show all of the bulk solid species in the mixture. Solid species are species that are deposit to, or etch from, wall boundaries or discrete-phase particles (for example, Si(s)) and do not exist as fluid-phase species. If you are modeling wall surface reactions with site balancing, where species adsorb onto the wall surface, react, and then desorb off the surface, the **Selected Site Species** list will show all of the site species in the mixture.

The use of solid and site species with wall surface reactions is described in Wall Surface Reactions and Chemical Vapor Deposition (p. 995). See Particle Surface Reactions (p. 1001) for information about particle surface reactions.

Important

The order of the species in the **Selected Species** list is very important. ANSYS Fluent considers the last species in the list to be the bulk species. You should therefore be careful to retain the most abundant species (by mass) as the last species when you add species to or delete species from a mixture material.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Available Materials** list shows materials that are available but not in the mixture. Generally, you will see air in this list, since air is always available by default.

14.1.4.1.2. Adding Species to the Mixture

If you are creating a mixture from nothing or starting from an existing mixture and adding some missing species, you will first need to load the desired species from the database (or create them, if they are not present in the database) so that they will be available to the solver. You will need to close the **Species** dialog box before you begin, since it is a "modal" dialog box that will not allow you to do anything else when it is open. The procedure for adding species is as follows:

1. In the **Create/Edit Materials** dialog box, click the **Fluent Database...** button to open the **Fluent Database Materials** dialog box and copy the desired species, as described in Copying Materials from the ANSYS Fluent Database (p. 464). Remember that the constituent species of the mixture are fluid materials, so you should select **fluid** as the **Material Type** in the **Fluent Database Materials** dialog box to see the correct list of choices. Note that available solid and site species (for surface reactions) are also contained in the **fluid** list.

   Important

   If you do not see the species you are looking for in the database, you can create a new fluid material for that species, following the instructions in Creating a New Material (p. 466), and then continue with step 2, below.

2. Re-open the **Species** dialog box. You will see that the fluid materials you copied from the database (or created) are listed in the **Available Materials** list.

3. To add a species to the mixture, select it in the **Available Materials** list and click the **Add** button below the **Selected Species** list (or below the **Selected Site Species** or **Selected Solid Species** list, to define a site or solid species). The species will be added to the end of the relevant list and removed from the **Available Materials** list.

4. Repeat the previous step for all the desired species. When you are finished, click the **OK** button.

Important

Adding a species to the list will alter the order of the species. You should be sure that the last species in the list is the bulk species, and you should check all cell and boundary zone conditions, under-relaxation factors, and other solution parameters that you have set, as described in detail in the following sections.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.4.1.3. Removing Species from the Mixture

To remove a species from the mixture, simply select it in the **Selected Species** list (or the **Selected Site Species** or **Selected Solid Species** list) and click the **Remove** button below the list. The species will be removed from the list and added to the **Available Materials** list.

Important

- Removing a species from the list will alter the order of the species. You should be sure that the last species in the list is the bulk species, and you should check any cell zone or boundary conditions, under-relaxation factors, or other solution parameters that you have set, as described in detail in the following sections.
- Any species that is a reactant, product, or enhanced third-body in an active reaction cannot be deleted from the mixture material.

14.1.4.1.4. Reordering Species

If you find that the last species in the **Selected Species** list is not the most abundant species (as it should be), you will need to rearrange the species to obtain the proper order.

1. Remove the bulk species from the **Selected Species** list. It will now appear in the **Available Species** list.
2. Add the species back in again. It will automatically be placed at the end of the list.

14.1.4.1.5. The Naming and Ordering of Species

As discussed previously, you should retain the most abundant species as the last one in the **Selected Species** list when you add or remove species. Additional considerations you should be aware of when adding and deleting species are presented here.

There are three characteristics of a species that identify it to the solver: name, chemical formula, and position in the list of species in the **Species** dialog box. Changing these characteristics will have the following effects:

- You can change the **Name** of a species (using the Create/Edit Materials Dialog Box (p. 2302), as described in Renaming an Existing Material (p. 463)) without any consequences.
- You should *never* change the given **Chemical Formula** of a species.
- You will change the order of the species list if you add or remove any species. When this occurs, all cell zone or boundary conditions, solver parameters, and solution data for species will be reset to the default values. (Solution data, cell zone or boundary conditions, and solver parameters for other flow variables will not be affected.) Therefore, if you add or remove species you should take care to redefine species cell zone and boundary conditions and solution parameters for the newly defined problem. In addition, you should recognize that patched species concentrations or concentrations stored in any data file that was based on the original species ordering will be incompatible with the newly defined problem. You can use the data file as a starting guess, but you should be aware that the species concentrations in the data file may provide a poor initial guess for the newly defined model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.4.2. Defining Reactions

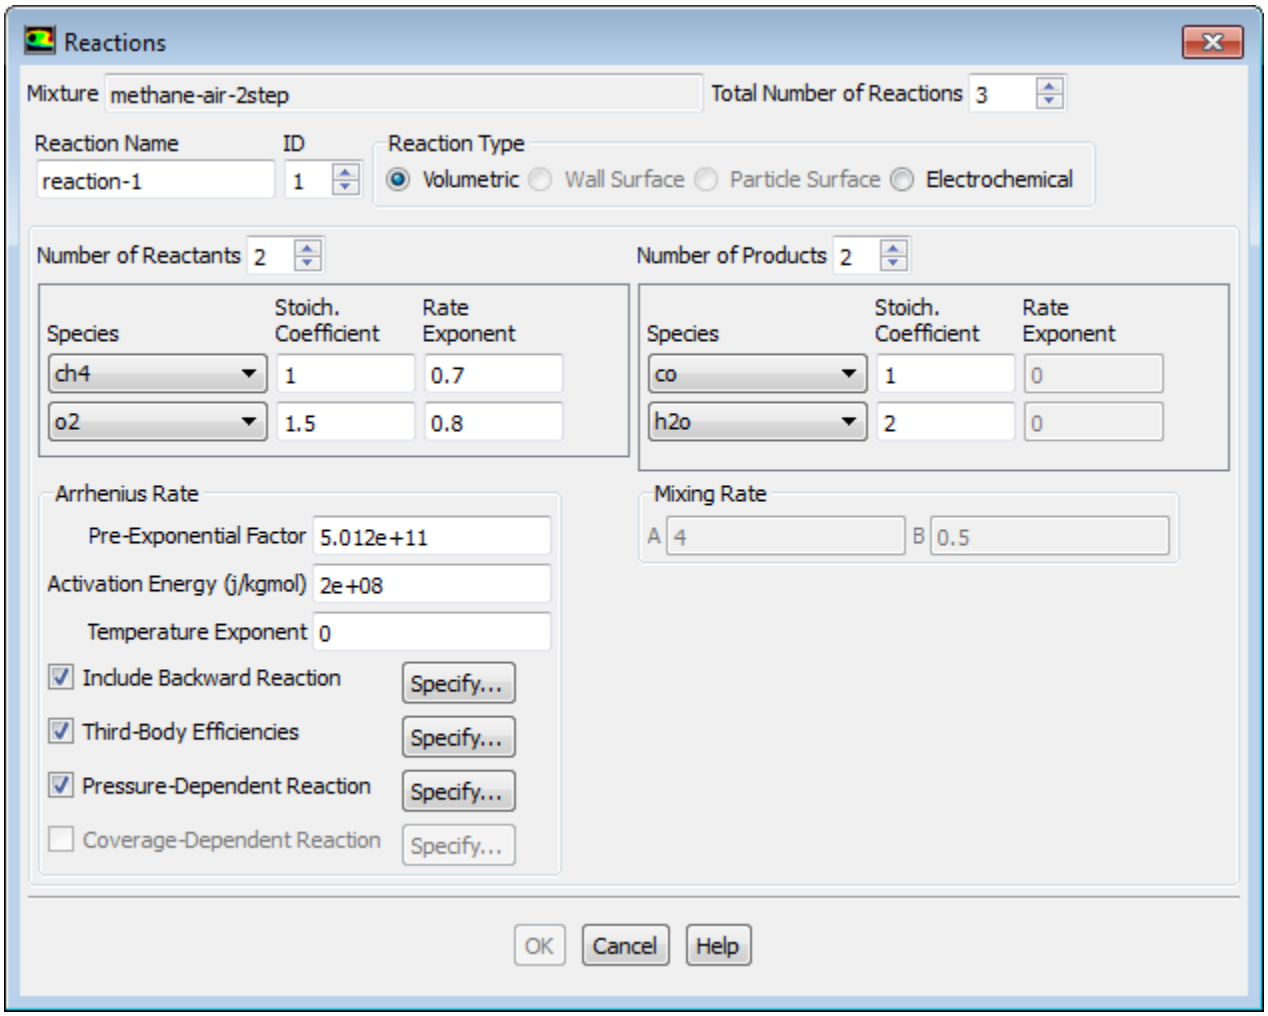
If your ANSYS Fluent model involves chemical reactions, you can define the reactions in which the defined species participate. This will be necessary only if you are creating a mixture material from nothing, you have modified the species, or you want to redefine the reactions for some other reason.

Depending on which turbulence-chemistry interaction model you selected in the **Species Model** dialog box (see Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960)), the appropriate reaction model will be displayed in the **Reaction** drop-down list in the **Edit Material** dialog box. If you are using the **Laminar Finite-Rate** or **Eddy-Dissipation Concept** model, the reaction model will be **finite-rate**; if you are using the **Eddy-Dissipation** model, the reaction model will be **eddy-dissipation**; if you are using the **Finite-Rate/Eddy-Dissipation** model, the reaction model will be **finite-rate/eddy-dissipation**.

14.1.4.2.1. Inputs for Reaction Definition

To define the reactions, click the **Edit...** button to the right of **Reaction**. The **Reactions** dialog box (Figure 14.9: The Reactions Dialog Box (p. 977)) will open.

Figure 14.9: The Reactions Dialog Box



The steps for defining reactions are as follows:

1. Set the total number of reactions (volumetric reactions, wall surface reactions, and particle surface reactions) in the **Total Number of Reactions** field. Use the arrows to change the value, or type in the value and press **Enter**.

   Note that if your model includes discrete-phase combusting particles, you should include the particulate surface reaction(s) (for example, char burnout, multiple char oxidation) in the number of reactions *only* if you plan to use the multiple surface reactions model for surface combustion.

2. Specify the **Reaction Name** of the reaction you want to define.

3. Set the **ID** of the reaction you want to define. Again, if you type in the value be sure to press **Enter**.

4. If this is a fluid-phase reaction, keep the default selection of **Volumetric** as the **Reaction Type**. If this is a wall surface reaction (described in Wall Surface Reactions and Chemical Vapor Deposition (p. 995)) or a particle surface reaction (described in Particle Surface Reactions (p. 1001)), select **Wall Surface** or **Particle Surface** as the **Reaction Type**. See User Inputs for Particle Surface Reactions (p. 1001) for further information about defining particle surface reactions.

5. Specify how many reactants and products are involved in the reaction by increasing the value of the **Number of Reactants** and the **Number of Products**. Select each reactant or product in the **Species** drop-down list and then set its stoichiometric coefficient and rate exponent in the appropriate **Stoich. Coefficient** and **Rate Exponent** fields. The stoichiometric coefficient is the constant $\nu'_{i,r}$ or $\nu''_{i,r}$ in Equation 7.6 in the Theory Guide and the rate exponent is the exponent on the reactant or product concentration, $\eta'_{j,r}$ or $\eta''_{j,r}$ in Equation 7.7 in the Theory Guide.

   There are two general classes of reactions that can be handled by the **Reactions** dialog box, so it is important that the parameters for each reaction are entered correctly. The classes of reactions are as follows:

   - Global forward reaction (no reverse reaction): Product species generally do not affect the forward rate, so the rate exponent for all products ($\eta''_{j,r}$) should be 0. For reactant species, set the rate exponent ($\eta'_{j,r}$) to the desired value. If such a reaction is not an elementary reaction, the rate exponent will generally not be equal to the stoichiometric coefficient ($\nu'_{i,r}$) for that species. An example of a global forward reaction is the combustion of methane:

     $$CH_4+2O_2\rightarrow CO_2+2H_2O \tag{14.1}$$

     where $\nu'_{CH_4}=1$, $\eta'_{CH_4}=0.2$, $\nu'_{O_2}=2$, $\eta'_{O_2}=1.3$, $\nu''_{CO_2}=1$, $\eta''_{CO_2}=0$, $\nu''_{H_2O}=2$, and $\eta''_{H_2O}=0$.

     Figure 14.9: The Reactions Dialog Box (p. 977) shows the coefficient inputs for the combustion of methane. See also the **methane-air** mixture material in the Fluent Database Materials Dialog Box (p. 2312).

     Note that, in certain cases, you may want to model a reaction where product species affect the forward rate. For such cases, set the product rate exponent ($\eta''_{j,r}$) to the desired value. An example of such a reaction is the gas-shift reaction (see the **carbon-monoxide-air** mixture material in the Fluent Database Materials Dialog Box (p. 2312)), in which the presence of water has an effect on the reaction rate:

     $$CO+\tfrac{1}{2}O_2+H_2O\rightarrow CO_2+H_2O$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In the gas-shift reaction, the rate expression may be defined as:

$$k[CO][O_2]^{1/4}[H_2O]^{1/2} \tag{14.2}$$

where $\nu'_{CO}=1$, $\eta'_{CO}=1$, $\nu'_{O_2}=0.5$, $\eta'_{O_2}=0.25$, $\nu''_{CO_2}=1$, $\eta''_{CO_2}=0$, $\nu''_{H_2O}=0$, and $\eta''_{H_2O}=0.5$.

- Reversible reaction: An elementary chemical reaction that assumes the rate exponent for each species is equivalent to the stoichiometric coefficient for that species. An example of an elementary reaction is the oxidation of SO_2 to SO_3:

  $SO_2+\frac{1}{2}O_2 \rightleftharpoons SO_3$

  where $\nu'_{SO_2}=1$, $\eta'_{SO_2}=1$, $\nu'_{O_2}=0.5$, $\eta'_{O_2}=0.5$, $\nu''_{SO_3}=1$, and $\eta''_{SO_3}=1$.

  See step 7 below for information about how to enable reversible reactions.

6. If you are using the laminar finite-rate, finite-rate/eddy-dissipation, Eddy-Dissipation Concept or PDF Transport model for the turbulence-chemistry interaction, enter the following parameters for the Arrhenius rate in the **Arrhenius Rate** group box:

   Note

   All quantities for the Arrhenius rate parameters are in units of kgmol, m^3, and seconds.

   Pre-Exponential Factor

   (the constant A_r in Equation 7.9 in the Theory Guide). The units of A_r must be specified such that the units of the molar reaction rate, $\hat{R}_{i,r}$ in Equation 7.5 in the Theory Guide, are moles/volume-time (for example, kmol/m^3-s) and the units of the volumetric reaction rate, R_i in Equation 7.5 in the Theory Guide, are mass/volume-time (for example, kg/m^3-s).

   Important

   It is important to note that if you have selected the British units system, the Arrhenius factor should still be entered in SI units. This is because ANSYS Fluent applies no conversion factor to your input of A_r (the conversion factor is 1.0) when you work in British units, as the correct conversion factor depends on your inputs for $\nu'_{i,r}$, β_r, and so on.

   Activation Energy

   (the constant E_r in the forward rate constant expression, Equation 7.9 in the Theory Guide).

   Temperature Exponent

   (the value for the constant β_r in Equation 7.9 in the Theory Guide).

   Third-Body Efficiencies

   (the values for $\gamma_{j,r}$ in Equation 7.8 in the Theory Guide). If you have accurate data for the efficiencies and want to include this effect on the reaction rate (that is, include Γ in Equation 7.7 in the Theory Guide), select the **Third Body Efficiencies** option and click the **Specify...** button to open the Third-Body Efficiency Dialog Box (p. 2338) (Figure 14.10: The Third-Body Efficiency Dialog Box (p. 980)).

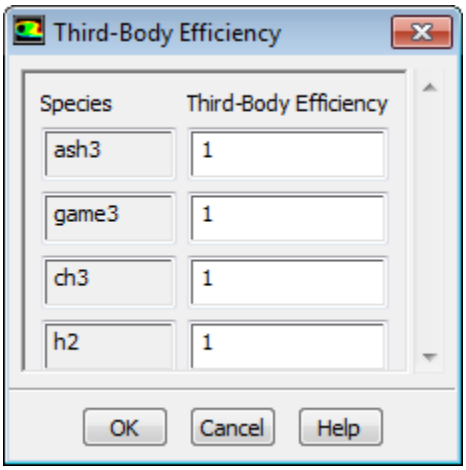
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For each **Species** in the dialog box, specify the **Third-Body Efficiency**.

Important

It is not necessary to include the third-body efficiencies. You should not enable the **Third-Body Efficiencies** option unless you have accurate data for these parameters.

Figure 14.10: The Third-Body Efficiency Dialog Box

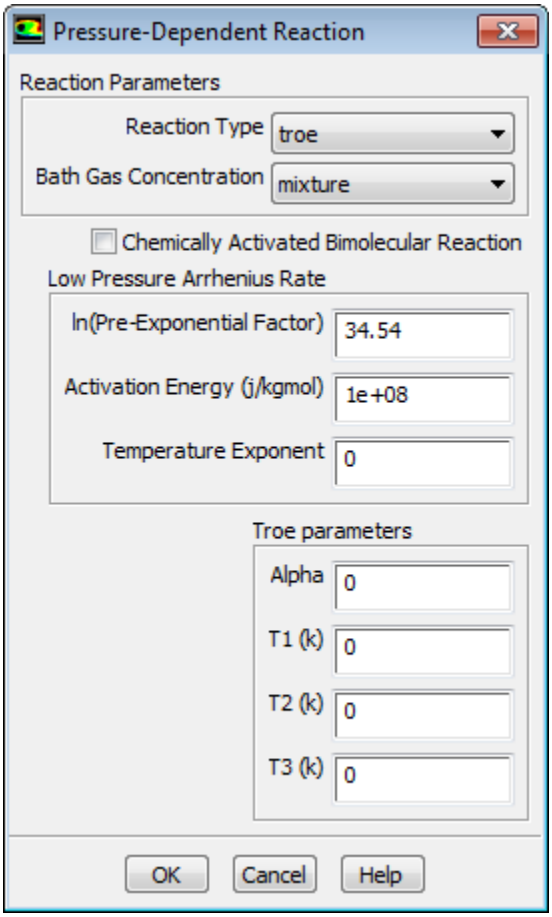


Pressure-Dependent Reaction

(if relevant) If you are using the laminar finite-rate or Eddy-Dissipation Concept model for turbulence-chemistry interaction, or have selected the composition PDF transport model (see Modeling a Composition PDF Transport Problem (p. 1113)), and the reaction is a pressure fall-off reaction (see Pressure-Dependent Reactions in the Theory Guide), enable the **Pressure-Dependent Reaction** option for the **Arrhenius Rate** and click the **Specify...** button to open the **Pressure-Dependent Reaction** dialog box (Figure 14.11: The Pressure-Dependent Reaction Dialog Box (p. 981)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.11: The Pressure-Dependent Reaction Dialog Box



Under **Reaction Parameters**, select the appropriate **Reaction Type** (**lindemann**, **troe**, or **sri**). See Pressure-Dependent Reactions in the Theory Guide for details about the three methods.

Next, specify if the **Bath Gas Concentration** ($[M]$ in Equation 7.18 in the Theory Guide) is to be defined as the concentration of the **mixture**, or as the concentration of one of the mixture's constituent species, by selecting the appropriate item in the drop-down list.

Enabling the **Chemically Activated Bimolecular Reaction** option results in a net rate constant at any pressure being defined as Equation 7.24 in the Theory Guide.

The parameters you specified under **Arrhenius Rate** in the **Reactions** dialog box represent the high-pressure Arrhenius parameters. You can, however, specify values for the following parameters under **Low Pressure Arrhenius Rate**:

ln(Pre-Exponential Factor)

(A_{low} in Equation 7.16 in the Theory Guide) The pre-exponential factor A_{low} is often an extremely large number, so you will input the natural logarithm of this term.

Activation Energy

(E_{low} in Equation 7.16 in the Theory Guide)

Temperature Exponent

(β_{low} in Equation 7.16 in the Theory Guide)

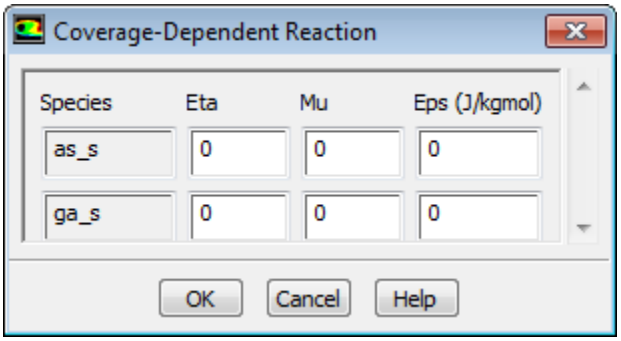
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you selected **troe** for the **Reaction Type**, you can specify values for **Alpha**, **T1**, **T2**, and **T3** (α, T_1, T_2, and T_3 in Equation 7.21 in the Theory Guide) under **Troe parameters**. If you selected **sri** for the **Reaction Type**, you can specify values for **a**, **b**, **c**, **d**, and **e** (a, b, c, d, and e in Equation 7.22 in the Theory Guide) under **SRI parameters**.

Coverage Dependent Reaction

If you are modeling **Wall Surface** reactions with site-balancing and you have reaction rates that depend on site coverages, you can enable the **Coverage Dependent Reaction** option. Click **Specify...** to open the **Coverage Dependent Reaction** dialog box (Figure 14.12: The Coverage Dependent Reaction Dialog Box (p. 982)) and input the coverage parameters.

Figure 14.12: The Coverage Dependent Reaction Dialog Box



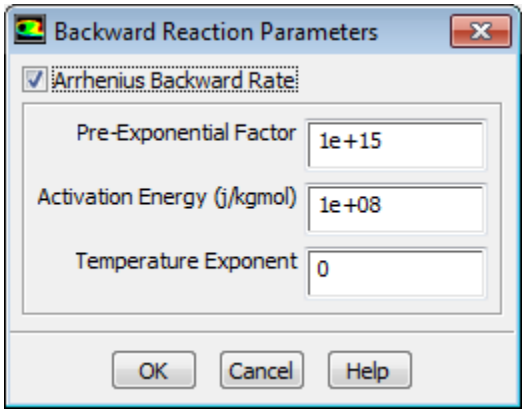
In the **Coverage Dependent Reaction** dialog box, all the site species of the reaction will be present with a default value of 0 for all the parameters, corresponding to no surface coverage modification. Enter the relevant values of the parameters μ, ε, and η (as defined in Equation 7.48 in the Theory Guide) for all the species for which the reaction has coverage dependence. μ and ε are dimensionless, and η is in units of J/kgmol.

7. If you are using the laminar finite-rate, Eddy-Dissipation Concept or PDF Transport model for turbulence-chemistry interaction, and the reaction is reversible, enable the **Include Backward Reaction** option for the **Arrhenius Rate**. When this option is enabled, you will not be able to edit the **Rate Exponent** for the product species, which instead will be set to be equivalent to the corresponding product **Stoich. Coefficient**. By default, ANSYS Fluent calculates the reverse reaction rate constants using Equation 7.10 in the *Fluent Theory Guide*. You can overwrite the ANSYS Fluent's default parameters for the reactions or define your own reactions. In both scenarios, you also need to specify the standard-state enthalpy and standard-state entropy for mixture material. ANSYS Fluent will use these values in the calculation of the backward reaction rate constant (Equation 7.10 in the *Fluent Theory Guide*).

   In addition, you have the option to provide your own backward reaction parameters. To do this, click **Specify...** next to **Include Backward Reaction** and enable the **Arrhenius Backward Rate** option in the **Backward Reaction Parameters** dialog box that opens (see Figure 14.13: Backward Reaction Parameters Dialog Box (p. 983)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.13: Backward Reaction Parameters Dialog Box



You can specify the following backward rate parameters:

Pre-Exponential Factor
(the constant $A_{b,r}$ in Equation 7.14 in the *Fluent Theory Guide*).

Activation Energy
(the constant $E_{b,r}$ in the backward rate constant expression in Equation 7.14 in the *Fluent Theory Guide*).

Temperature Exponent
(the constant $\beta_{b,r}$ in Equation 7.14 in the *Fluent Theory Guide*).

ANSYS Fluent will use your custom values to calculate the backward rate constant of the reversible reaction according to Equation 7.14 in the *Fluent Theory Guide*.

Note that the reversible reaction option is not available for either the eddy-dissipation or the finite-rate/eddy-dissipation turbulence-chemistry interaction model.

8. If you are using the eddy-dissipation or finite-rate/eddy-dissipation model for turbulence-chemistry interaction, you can enter values for **A** and **B** under the **Mixing Rate** heading. These values should not be changed unless you have reliable data. In most cases you will use the default values.

   A is the constant A in the turbulent mixing rate (Equation 7.25 and Equation 7.26 in the Theory Guide) when it is applied to a species that appears as a reactant in this reaction. The default setting of 4.0 is based on the empirically derived values given by Magnussen et al. [64] (p. 2890).

   B is the constant B in the turbulent mixing rate (Equation 7.26 in the Theory Guide) when it is applied to a species that appears as a product in this reaction. The default setting of 0.5 is based on the empirically derived values given by Magnussen et al. [64] (p. 2890).

9. Repeat steps 2–8 for each reaction you need to define. After defining all reactions, click **OK**.

14.1.4.2.2. Defining Species and Reactions for Fuel Mixtures

Quite often, combustion systems will include fuel that is not easily described as a pure species (such as CH_4 or C_2H_6). Complex hydrocarbons, including fuel oil or even wood chips, may be difficult to define in terms of such pure species. However, if you have available the heating value and the ultimate analysis (elemental composition) of the fuel, you can define an equivalent fuel species and an equivalent heat of formation for this fuel. Consider, for example, a fuel known to contain 50% C, 6% H, and 44% O by weight. Dividing by atomic weights, you can arrive at a "fuel" species with the molecular formula $C_{4.17}$

$H_6\ O_{2.75}$. You can start from a similar, existing species or create a species from nothing, and assign it a molecular weight of 100.04 kg/kmol (4.17 × 12 + 6 × 1 + 2.75 × 16). The chemical reaction would be considered to be

$$C_{4.17}H_6O_{2.75}+4.295O_2\rightarrow 4.17CO_2+3H_2O \tag{14.3}$$

You will need to set the appropriate stoichiometric coefficients for this reaction.

The heat of formation (or standard-state enthalpy) for the fuel species can be calculated from the known heating value ΔH since

$$\Delta H=\sum_{i=1}^{N}h_i^0\left(\nu_{i,r}''-\nu_{i,r}'\right) \tag{14.4}$$

where h_i^0 is the standard-state enthalpy on a molar basis. Note the sign convention in Equation 14.4 (p. 984) : ΔH is negative when the reaction is exothermic.

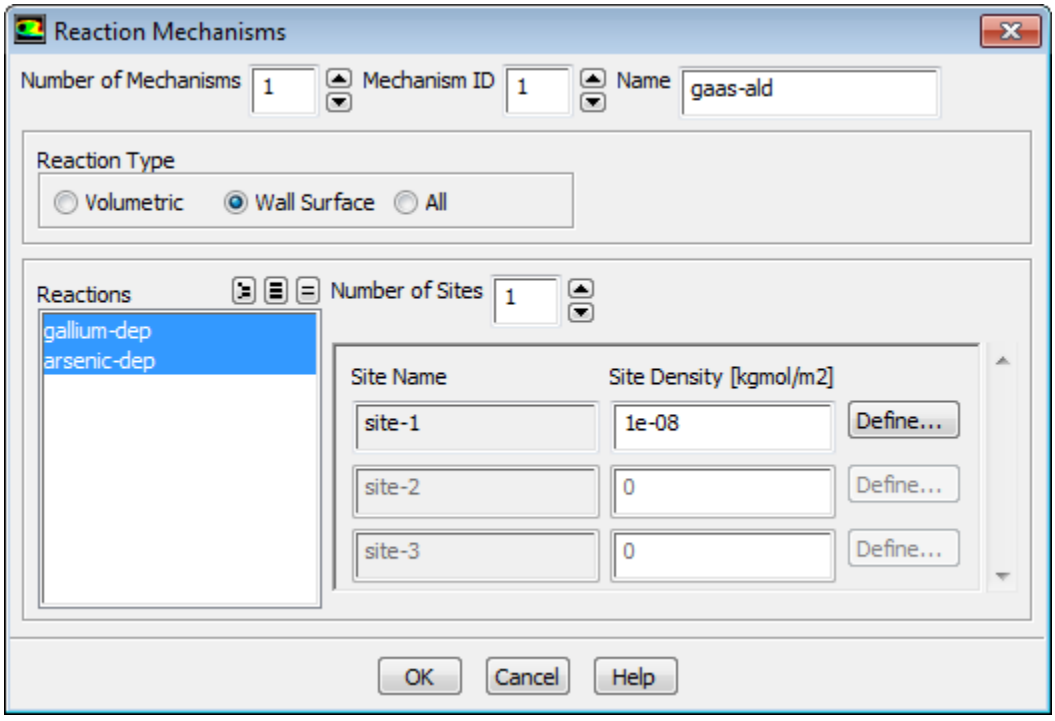
14.1.4.3. Defining Zone-Based Reaction Mechanisms

If your ANSYS Fluent model involves reactions that are confined to a specific area of the domain, you can define "reaction mechanisms" to enable different reactions selectively in different geometrical zones. You can create reaction mechanisms by selecting reactions from those defined in the **Reactions** dialog box and grouping them. You can then assign a particular mechanism to a particular zone.

14.1.4.3.1. Inputs for Reaction Mechanism Definition

To define a reaction mechanism, click the **Edit...** button to the right of **Mechanism**. The Reaction Mechanisms Dialog Box (p. 2342) (Figure 14.14: The Reaction Mechanisms Dialog Box (p. 984)) will open.

Figure 14.14: The Reaction Mechanisms Dialog Box



The steps for defining a reaction mechanism are as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Set the total number of mechanisms in the **Number of Mechanisms** field. Use the arrows to change the value, or type the value and press **Enter**.

2. Set the **Mechanism ID** of the mechanism you want to define. Again, if you type in the value, be sure to press **Enter**.

3. Specify the **Name** of the mechanism.

4. Select the type of reaction to add to the mechanism under **Reaction Type**. If you select **Volumetric**, the **Reactions** list will display all available fluid-phase reactions. If you select **Wall Surface** or **Particle Surface**, the **Reactions** list will display all available wall surface reactions (described in Wall Surface Reactions and Chemical Vapor Deposition (p. 995)) or particle surface reactions (described in Particle Surface Reactions (p. 1001)). If you select **All**, the **Reactions** list will display all available reactions. This option is meant for backward compatibility with ANSYS Fluent 6.0 or earlier cases.

5. Select the reactions to be included in the mechanism.

   - For **Volumetric** or **Particle Surface** reactions, select available reactions for the mechanism in the **Reactions** list.

   - For **Wall Surface** reactions, use the following procedure:

     a. Select available wall surface reactions for the mechanism in the **Reactions** list.

     b. If any site species appear in the selected reaction(s), set the number of sites in the **Number of Sites** field. Use the arrows to change the value, or type the value and press **Enter**. See Reaction-Diffusion Balance for Surface Chemistry in the Theory Guide for details about site species in wall surface reactions.

     c. If you specify a **Number of Sites** that is greater than zero, specify the properties of the site.

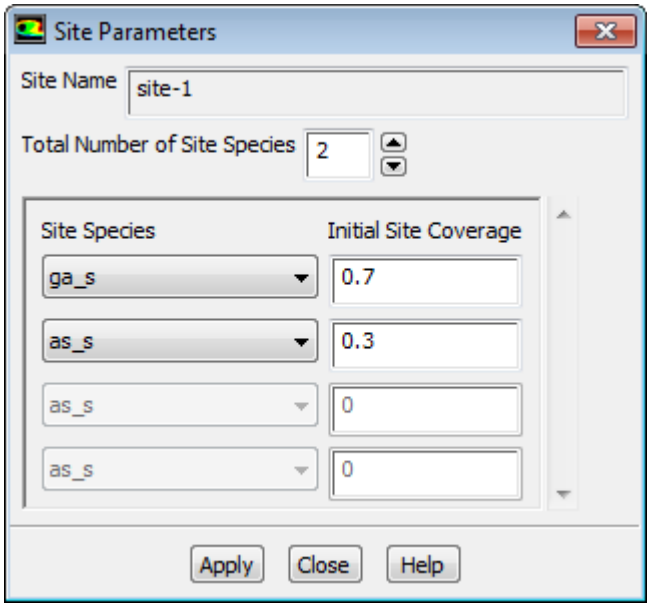
        Site Name
        (optional)

        Site Density
        (in kmol/m^2) This value is typically in the range of 10^{-8} to 10^{-6}.

        Click the **Define...** button. This will open the Site Parameters Dialog Box (p. 2344) (Figure 14.15: The Site Parameters Dialog Box (p. 986)), where you will define the parameters of the site species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.15: The Site Parameters Dialog Box



Site Name

is the optional name of the site that was specified in the **Reaction Mechanisms** dialog box.

Total Number of Site Species

is the number of adsorbed species that are to be modeled at the site. (Use the arrows to change the value, or type the value and press **Enter**.)

Under **Site Species**, select the appropriate species from the drop-down list(s) and specify the fractional **Initial Site Coverage** for each species. For steady-state calculations, it is recommended (though not strictly required) that the initial values of **Initial Site Coverage** sum to unity. For transient calculations, it is required that these values sum to unity.

Click **Apply** in the **Site Parameters** dialog box to store the new values.

6. Repeat steps 2–5 for each reaction mechanism you need to define. When you are finished defining all reaction mechanisms, click **OK**.

14.1.4.4. Defining Physical Properties for the Mixture

When your ANSYS Fluent model includes chemical species, the following physical properties must be defined, either by you or by the database, for the mixture material:

- density, which you can define using the gas law or as a volume-weighted function of composition
- viscosity, which you can define as a function of composition
- thermal conductivity and specific heat (in problems involving solution of the energy equation), which you can define as functions of composition
- mass diffusion coefficients and Schmidt number, which govern the mass diffusion fluxes (Equation 7.2 and Equation 7.3 in the Theory Guide)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Detailed descriptions of these property inputs are provided in Physical Properties (p. 459).

Important

Remember to click the **Change/Create** button when you are done setting the properties of the mixture material. The properties that appear for each of the constituent species will depend on your settings for the properties of the mixture material. If, for example, you specify a composition-dependent viscosity for the mixture, you will need to define viscosity for each species.

14.1.4.5. Defining Physical Properties for the Species in the Mixture

For each of the fluid materials in the mixture, you (or the database) must define the following physical properties:

- molecular weight, which is used in the gas law and/or in the calculation of reaction rates and mole-fraction inputs or outputs
- standard-state (formation) enthalpy and reference temperature (in problems involving solution of the energy equation)
- viscosity, if you defined the viscosity of the mixture material as a function of composition
- thermal conductivity and specific heat (in problems involving solution of the energy equation), if you defined these properties of the mixture material as functions of composition
- standard-state entropy, if you are modeling reversible reactions
- thermal and momentum accommodation coefficients, if you have enabled the low-pressure boundary slip model.

Detailed descriptions of these property inputs are provided in Physical Properties (p. 459).

Important

Global reaction mechanisms with one or two steps inevitably neglect the intermediate species. In high-temperature flames, neglecting these dissociated species may cause the temperature to be overpredicted. A more realistic temperature field can be obtained by increasing the specific heat capacity for each species. Rose and Cooper [94] (p. 2892) have created a set of specific heat polynomials as a function of temperature.

The specific heat capacity for each species is calculated as

$$c_p(T) = \sum_{k=0}^{m} a_k T^k \tag{14.5}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The modified c_p polynomial coefficients (J/kg-K) are provided in Table 14.1: Modified Specific Heat Capacity (Cp) Polynomial Coefficients (p. 988).

Table 14.1: Modified Specific Heat Capacity (Cp) Polynomial Coefficients

	CO_2	H_2O	O_2
a_0	5.35446e+02	1.93780e+03	8.76317e+02
a_1	1.27867e+00	−1.18077e+00	1.22828e −01
a_2	−5.46776e −04	3.64357e −03	5.58304e −04
a_3	−2.38224e −07	−2.86327e −06	−1.20247e −06
a_4	1.89204e −10	7.59578e −10	1.14741e −09
a_5	—–	—–	−5.12377e −13
a_6	—–	—–	8.56597e −17

14.1.5. Setting up Coal Simulations with the Coal Calculator Dialog Box

The **Coal Calculator** dialog box automates calculation and setting of the relevant input parameters for the Species, Discrete-Phase (DPM) and Pollutant models associated with coal combustion. It is available in the **Species** dialog box for the **Species Transport** model when the **Eddy-Dissipation** or **Finite-Rate/Eddy-Dissipation** turbulence-chemistry option is selected. You can define up to three coal streams in your simulation using the **Number of Coal Streams** entry box.

For each coal stream selected in the **Coal Stream ID**, you need to define the following properties:

1. Coal **Proximate Analysis**, which is the mass fraction of **Volatile, Fixed Carbon, Ash** and **Moisture** in the coal. ANSYS Fluent will normalize the mass fractions so that they sum to unity.

2. Coal **Ultimate Analysis**, which is the mass fraction of atomic **C, H, O, N** and optionally **S**, in the Dry-Ash-Free (DAF) coal. ANSYS Fluent will normalize the mass fractions so that they sum to unity.

3. A choice of **One-step** or **Two-step** chemical mechanism. The one-step mechanism is,

$$vol + \nu_{O_2} O_2 \rightarrow \nu_{CO_2} CO_2 + \nu_{H_2O} H_2O + \nu_{SO_2} SO_2 + \nu_{N_2} N_2 \tag{14.6}$$

   The two-step mechanism involves oxidation of volatiles to CO in the first reaction and oxidation of CO to CO_2 in the second reaction:

$$\begin{aligned} vol + \nu_{O_2} O_2 &\rightarrow \nu_{CO} CO + \nu_{CO_2} CO_2 + \nu_{H_2O} H_2O + \nu_{SO_2} SO_2 + \nu_{N_2} N_2 \\ CO + 0.5 O_2 &\rightarrow CO_2 \end{aligned} \tag{14.7}$$

   The stoichiometric coefficients in Equation 14.6 (p. 988) and Equation 14.7 (p. 988) are calculated from the ultimate and proximate analyses.

4. An option to **Include SO2**. When this is enabled, an input for the atomic mass fraction of sulphur, **S**, appears in the ultimate analysis frame.

5. The **Coal Particle Material Name**. A DPM combusting-particle material will be created with this name. The default name is *coal-particle*.

6. The **Coal As-Received HCV**, where HCV denotes the Higher Calorific Value.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. **Volatile Molecular Weight** is the molecular weight of pure volatiles.

8. The **CO/CO2 Split in Reaction 1 Products** can be used to specify the molar fraction of CO to CO_2 in the first reaction of Equation 14.7 (p. 988). The default value of 1 implies that all carbon is reacted to CO, with no CO_2 produced.

9. The **High Temperature Volatile Yield**. Enhanced devolatization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction. To model this, the actual volatile fraction used is calculated as that specified in the **Proximate Analysis** input multiplied by the **High Temperature Volatile Yield**. The actual fixed carbon fraction is then calculated as one minus the sum of the actual volatile, ash and moisture fractions.

10. **Fraction of N in Char (DAF)**. This input is used in calculating the split of atomic nitrogen for the Fuel NOx model.

11. **Coal Dry Density** is used to calculate the volume fraction of liquid-water for the **Wet Combustion** option in the **Injections** dialog box.

Clicking **Apply** will save the **Coal Property** data for the selected **Coal Stream ID**. When you click **OK**, ANSYS Fluent makes the following changes:

1. A Mixture material is created, named *coal-volatiles-air*, with a one or two step reaction mechanism as specified in the **Mechanism** option. If the **Fluid** material species (O_2,CO,CO_2 and so on) do not exist, they are created. A **Fluid** material called *coal-volatiles*, is also created with a standard state enthalpy calculated from the ultimate and proximate analyses, as-received HCV and volatile molecular weight. For the second and third coal streams, additional **Fluid** materials and reactions with the properties corresponding to the second and third coal streams are also created in the mixture.

2. A combusting-particle material is created for each coal stream with **Volatile Component Fraction** and **Combustible Fraction** calculated from the ultimate and proximate analyses. The discrete phase model (DPM) is enabled.

3. For the fuel NOx model, the default fuel species is set to *vol*, the char N conversion is set to *NO*, and the fuel NOx **Volatile** and **Char** mass fractions are set according to the ultimate and proximate compositions of the first coal stream. Note that even though some of the default fuel NOx parameters are changed, the fuel NOx model itself is not enabled.

4. If the **Moisture** mass fraction in the coal proximate analysis is nonzero, then the **Wet Combustion** option is enabled in the **Coal Calculator** dialog box, and all subsequent injections that are created will have wet combustion enabled. The liquid material will be set to `water-liquid`, and the volume fraction of water will be calculated from the **Moisture** mass fraction specified in the proximate analysis and the **Coal Dry Density**. The wet combustion settings are not modified for existing injections. The **Density** for the combusting-particle in the **Create/Edit Materials** dialog box will also be set to **Coal Dry Density**.

Note

Irrespective of the **Wet Combustion** option in the **Coal Calculator** dialog box you can modify the **Wet Combustion** model setting for the injections in the **Set Injection Properties** dialog box. In addition, you will need to take care to enter the flow-rate of each injection on a wet or dry basis, consistent with the **Wet Combustion** model setting.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.6. Defining Cell Zone and Boundary Conditions for Species

You will need to specify the inlet mass fraction for all species in your simulation. In addition, for pressure outlets you will set species mass fractions to be used in case of backflow. At walls, ANSYS Fluent will apply a zero-gradient (zero-flux) boundary condition for all species by default, although you can change each species boundary condition to a specified value. If you have surface reactions defined (see Wall Surface Reactions and Chemical Vapor Deposition (p. 995)), you can choose to enable wall-surface reactions and select the chemical mechanism. For fluid zones, you also have the option of specifying a reaction mechanism. Input of cell zone and boundary conditions is described in Cell Zone and Boundary Conditions (p. 237).

Important

- Non-reflecting boundary conditions (NRBCs) are not compatible with species transport models. They are mainly used to solve ideal-gas single species flow. For information about NRBCs, see Boundary Acoustic Wave Models (p. 405).
- Note that you will explicitly set mass fractions only for the first $N-1$ species. The solver will compute the mass fraction of the last species by subtracting the total of the specified mass fractions from 1. If you want to explicitly specify the mass fraction of the last species, you must reorder the species in the list (in the Create/Edit Materials Dialog Box (p. 2302)), as described in Defining Properties for the Mixture and Its Constituent Species (p. 972).

14.1.6.1. Diffusion at Inlets with the Pressure-Based Solver

For the pressure-based solver in ANSYS Fluent, the net transport of species at inlets consists of both convection and diffusion components. The convection component is fixed by the specified inlet species mass or mole fraction, whereas the diffusion component depends on the gradient of the computed species concentration field (which is not known a priori). At very small convective inlet velocities, for example when modeling perforated combustion liners with an inlet, substantial mass can be gained or lost through the inlet due to diffusion. For this reason, inlet diffusion is disabled by default, but can be enabled with the **Inlet Diffusion** option in the **Species Model** dialog box.

Setup → Models → Species → Edit...

14.1.7. Defining Other Sources of Chemical Species

You can define a source or sink of a chemical species within the computational domain by defining a source term in the **Fluid** dialog box. You may choose this approach when species sources exist in your problem but you do not want to model them through the mechanism of chemical reactions. Defining Mass, Momentum, Energy, and Other Sources (p. 297) describes the procedures you would follow to define species sources in your ANSYS Fluent model. If the source is not a constant, you can use a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

14.1.8. Solution Procedures for Chemical Mixing and Finite-Rate Chemistry

While many simulations involving chemical species may require no special procedures during the solution process, you may find that one or more of the solution techniques noted in this section helps to accelerate the convergence or improve the stability of more complex simulations. The techniques

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

outlined below may be of particular importance if your problem involves many species and/or chemical reactions, especially when modeling combusting flows.

14.1.8.1. Stability and Convergence in Reacting Flows

Obtaining a converged solution in a reacting flow can be difficult for a number of reasons. First, the impact of the chemical reaction on the basic flow pattern may be strong, leading to a model in which there is strong coupling between the mass/momentum balances and the species transport equations. This is especially true in combustion , where the reactions lead to a large heat release and subsequent density changes and large accelerations in the flow. All reacting systems have some degree of coupling, however, when the flow properties depend on the species concentrations. These coupling issues are best addressed by the use of a two-step solution process, as described below, and by the use of under-relaxation as described in Setting Under-Relaxation Factors (p. 1564).

A second convergence issue in reacting flows involves the magnitude of the reaction source term. When the ANSYS Fluent model involves very rapid reaction rates (reaction time scales are much faster than convection and diffusion time scales), the solution of the species transport equations becomes numerically difficult. Such systems are termed "stiff" systems. Stiff systems with finite-rate chemistry should be solved using either the pressure-based or density-based solver together with either **Stiff Chemistry Solver** or the **CHEMKIN-CFD Solver** (see Solution of Stiff Chemistry Systems (p. 992)). Finite-rate chemistry may also be used for turbulent combustion. For turbulent combustion, turbulence-chemistry interactions can either be neglected (**Finite-rate/No TCI** model) or accounted for using **Eddy-Dissipation Concept** or **PDF Transport** models.

14.1.8.2. Two-Step Solution Procedure (Steady-state Only)

Solving a reacting flow as a two-step process is a practical method for reaching a stable converged solution to your ANSYS Fluent problem. In this process, you begin by solving the flow, energy, and species equations with reactions disabled (the "cold-flow", or unreacting flow). When the basic flow pattern has thereby been established, you can re-enable the reactions and continue the calculation. The cold-flow solution provides a good starting solution for the calculation of the combusting system. This two-step approach to combustion modeling can be accomplished using the following procedure:

1. Set up the problem including all species and reactions of interest.

2. Temporarily disable reaction calculations by turning off **Volumetric** in the Species Model Dialog Box (p. 2216).

   Setup → **Models** → **Species** **Edit...**

3. Disable calculation of the product species in the Equations Dialog Box (p. 2511).

   Solution → **Controls** → **Equations...**

4. Calculate an initial (cold-flow) solution. (Note that it is generally not productive to obtain a fully converged cold-flow solution unless the non-reacting solution is also of interest to you.)

5. Enable the reaction calculations by turning on **Volumetric** again in the Species Model Dialog Box (p. 2216).

6. Enable all equations in the **Equations** dialog box. If you are using the **Finite-Rate/No TCI**, **Finite-Rate/Eddy-Dissipation**, **Eddy-Dissipation Concept** or **PDF Transport** model for the turbulence-chemistry interaction, you may need to patch an ignition source (as described in Ignition in Steady-State Combustion Simulations (p. 992)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.8.3. Density Under-Relaxation

One of the main reasons a combustion calculation can have difficulty converging is that large changes in temperature cause large changes in density, which can, in turn, cause instabilities in the flow solution. When you use the pressure-based solver, ANSYS Fluent allows you to under-relax the change in density to alleviate this difficulty. The default value for density under-relaxation is 1, but if you encounter convergence trouble you may want to reduce this to a value between 0.5 and 1 (in the **Solution Controls** task page).

Note that if you are using a real-gas model the solution might converge at a slower rate than when running ideal-gas flow. To improve the convergence performance of your analysis, you need to reduce the underrelaxation for density to values as low as 0.1.

14.1.8.4. Ignition in Steady-State Combustion Simulations

If you introduce fuel to an oxidant or have a premixed fuel/oxidant mixture, but you are not simulating the transient ignition process, then you must numerically force the solution to the burned state (rather than the unburned state). Generally, spontaneous ignition does not occur unless the temperature of the mixture exceeds the activation energy threshold required to maintain combustion. For steady-state ANSYS Fluent combustion simulations, whether you are using the species transport or PDF transport model and regardless of turbulence-chemistry interaction option, you have to supply an ignition source to initiate combustion. This ignition source may be a heated surface or inlet mass flow that heats the gas mixture above the required ignition temperature. Often, however, it is the equivalent of a spark: an initial solution state that causes combustion to proceed. You can supply this initial "spark" by patching a hot temperature into a region of the ANSYS Fluent model that contains an ignitable fuel/air mixture.

Solution → **Initialization** → **Patch...**

Depending on the model, you may need to patch both the temperature and the fuel/ oxidant/product concentrations to produce ignition in your model. The initial patch has no impact on the final steady-state solution—no more than the location of a match determines the final flow pattern of the torch that it lights. See Patching Values in Selected Cells (p. 1593) for details about patching initial values.

14.1.8.5. Solution of Stiff Chemistry Systems

When modeling stiff chemistry systems, such as flames with finite-rate kinetics, you can either use the pressure-based solver with the **Stiff Chemistry Solver** option enabled or **CHEMKIN-CFD Solver** selected as seen in the Species Model Dialog Box (p. 2216) (Figure 14.1: The Species Model Dialog Box (p. 961)), or the density-based solver.

For steady simulations using the pressure-based solver, the **Stiff Chemistry Solver** option approximates the reaction rate R_i in the species transport equation (see Equation 7.5 in the Theory Guide) as,

$$R_i^* = \frac{1}{\tau}\int_0^{\tau} R_i dt \tag{14.8}$$

where τ is an appropriate time-step. Note that as τ tends to zero the approximation becomes exact but the stiff numerics will cause the pressure-based solver to diverge. On the other hand, as τ tends to infinity, the approximated reaction rate R_i^* tends to zero and, while the numerical stiffness is alleviated, there is no reaction. In ANSYS Fluent, the default value for τ is set to one-tenth of the minimum convective or diffusive time-scale in the cell. This value was found to be sufficiently accurate and robust,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

although it can be modified using the `solve/set/stiff-chemistry` text command. ISAT is employed to integrate the stiff chemistry in Equation 14.8 (p. 992). Equation 14.8 (p. 992) is also applied for unsteady simulations, with τ = flow time step.

Details about the ISAT algorithm may be found in Particle Reaction in the Theory Guide and Using ISAT Efficiently (p. 1130). For efficient and accurate use of ISAT, a review of this section is highly recommended.

The density-based implicit solver may also be used with either chemistry solver option. This option allows a larger stable Courant (CFL) number specification, although additional calculations are required to calculate the eigenvalues of the chemical system Jacobian [127] (p. 2893). When enabling the stiff-chemistry solver with the density-based solver, the following must be specified:

- **Temperature Positivity Rate Limit**: limits new temperature changes by this factor multiplied by the old temperature. Its default value is 0.2.
- **Temperature Time Step Reduction**: limits the local CFL number when the temperature is changing too rapidly. Its default value is 0.25.
- **Max. Chemical Time Step Ratio**: limits the local CFL number when the chemical time scales (eigenvalues of the chemical Jacobian) become too large to maintain a well-conditioned matrix. Its default value is 0.9.

14.1.8.6. Eddy-Dissipation Concept Model Solution Procedure

Due to the high computational expense of the Eddy-Dissipation Concept model, it is recommended that you use the following procedure to obtain a solution using the pressure-based solver:

1. Calculate an initial solution using the equilibrium Non-premixed or Partially-premixed model (see Modeling Non-Premixed Combustion (p. 1025) and Modeling Partially Premixed Combustion (p. 1099)).
2. Import a CHEMKIN format reaction mechanism (see Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967)).
3. Enable the reaction calculations by turning on **Volumetric Reactions** in the **Species Model** dialog box and selecting **Eddy-Dissipation Concept** under **Turbulence-Chemistry Interaction**. Select the mechanism that you just imported as the **Mixture Material**.

   Setup → **Models** → **Species** **Edit...**
4. Set the species boundary conditions.

   Setup → **Boundary Conditions**
5. Disable the flow and turbulence and solve for the species and temperature only.
6. Enable all equations and iterate to convergence. Note that the default numerical parameters for the solution of the Eddy-Dissipation Concept equations are set to provide maximum robustness with slowest convergence. The convergence rate can be increased by setting the **Aggressiveness Factor** in the **Species** dialog box or with the text command:

   `define` → `models` → `species` → `set-turb-chem-interaction`

   The **Aggressiveness Factor** can be set from 0 (slow but stable) to 1 (fast but least stable). The default is 0.5

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.1.9. Postprocessing for Species Calculations

ANSYS Fluent can report chemical species as mass fractions, mole fractions, and molar concentrations. You can also display laminar and effective mass diffusion coefficients. The following variables are available for postprocessing of species transport and reaction simulations:

- **Mass fraction of species-n**
- **Mole fraction of species-n**
- **Molar Concentration of species-n**
- **Lam Diff Coef of species-n**
- **Eff Diff Coef of species-n**
- **Thermal Diff Coef of species-n**
- **Enthalpy of species-n** (pressure-based solver calculations only)
- **species-n Source Term** (density-based solver calculations only)
- **Relative Humidity**
- **TFM Thickening Factor** (Thickened Flame Model only)
- **TFM Omega** (Thickened Flame Model only)
- **TFM Thickening Factor** (turbulent cases (LES / DES / SAS / SBES / SDES) with Thickened Flame Model only)
- **Laminar Flame Speed** (Thickened Flame Model only)
- **Laminar Flame Thickness** (Thickened Flame Model only)
- **Cell Time Scale** (Eddy-Dissipation Concept and Laminar finite-rate stiff-chemistry only)
- **Fine Scale Mass fraction of species-n** (Eddy-Dissipation Concept model only)
- **EDC Cell Volume Fraction** (Eddy-Dissipation Concept model only)
- **Fine Scale Temperature** (Eddy-Dissipation Concept model only)
- **Net Rate of species-n** (Eddy-Dissipation Concept and Laminar finite-rate stiff-chemistry only)
- **Kinetic Rate of Reaction-n**
- **Turbulent Rate of Reaction-n**
- **Liquid species mass fraction of species-n** (solidification and melting model only)
- **Heat of Reaction**

These variables are contained in the **Species...**, **Temperature...**, and **Reactions...** categories of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1931) for a complete list of flow variables, field functions, and their definitions. Displaying

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Graphics (p. 1747) and Reporting Alphanumeric Data (p. 1885) explain how to generate graphics displays and reports of data.

14.1.9.1. Averaged Species Concentrations

Averaged species concentrations at inlets and exits, and across selected planes (that is, surfaces that you have created using **Create** in the **Setting Up Domain** ribbon tab (**Surface**group box)) within your model can be obtained using the Surface Integrals Dialog Box (p. 2616), as described in Surface Integration (p. 1920).

Results → **Reports** → **Surface Integrals** **Edit...**

Select the **Molar Concentration of species-n** for the appropriate species in the **Field Variable** drop-down list.

14.2. Wall Surface Reactions and Chemical Vapor Deposition

For gas-phase reactions, the reaction rate is defined on a volumetric basis and the rate of creation and destruction of chemical species becomes a source term in the species conservation equations. Heterogeneous surface reactions create sources (and sinks) of chemical species in the gas-phase as well, but also alter surface coverages for surface site reactions, and may deposit or etch species for bulk (solid) reactions.

For more information about the theoretical background of wall surface reactions and chemical vapor depositions, see Wall Surface Reactions and Chemical Vapor Deposition in the Theory Guide. Information about using wall surface reactions is presented in the following subsections:

14.2.1. Overview of Surface Species and Wall Surface Reactions
14.2.2. Importing a Surface Kinetic Mechanism in CHEMKIN Format
14.2.3. Manual Inputs for Wall Surface Reactions
14.2.4. Including Mass Transfer To Surfaces in Continuity
14.2.5. Wall Surface Mass Transfer Effects in the Energy Equation
14.2.6. Modeling the Heat Release Due to Wall Surface Reactions
14.2.7. Solution Procedures for Wall Surface Reactions
14.2.8. Postprocessing for Surface Reactions

14.2.1. Overview of Surface Species and Wall Surface Reactions

ANSYS Fluent treats chemical species adsorbed and desorbed, as well as those deposited into or etched from the bulk solid surfaces as distinct from the same chemical species in the gas. Similarly, surface reactions are defined distinctly and treated differently than gas-phase reactions involving the same chemical species.

Surface reactions can be limited so that they occur on only some of the wall boundaries (while the other wall boundaries remain free of surface reaction). The surface reaction rate is defined and computed per unit surface area, in contrast to the fluid-phase reactions, which are based on unit volume.

14.2.2. Importing a Surface Kinetic Mechanism in CHEMKIN Format

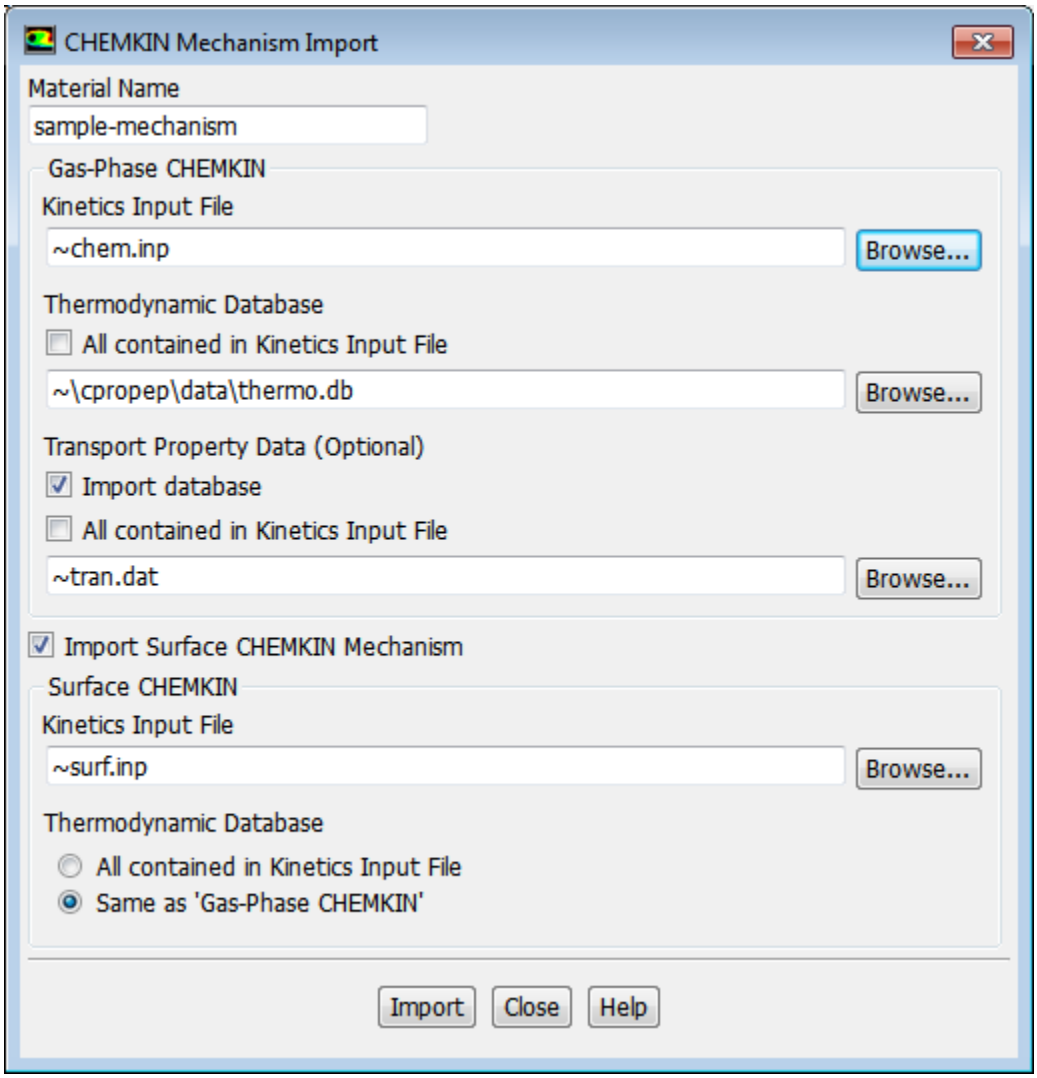
Importing surface kinetic mechanisms in CHEMKIN format requires that the gas-phase mechanism file accompanies the surface mechanism file for full compatibility with CHEMKIN (for more information on how to import the gas-phase mechanism, see Importing a Volumetric Kinetic Mechanism in CHEMKIN

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Format (p. 967)). If the gas-phase mechanism file is not available, then you will need to create one that you will import along with the surface mechanism file.

The mechanism files are imported into ANSYS Fluent using the **CHEMKIN Mechanism Import** dialog box (Figure 14.16: The CHEMKIN Mechanism Import Dialog Box for Surface Kinetics (p. 996)) which is opened by clicking **Import CHEMKIN Mechanism...** in the **Species Model** dialog box.

Figure 14.16: The CHEMKIN Mechanism Import Dialog Box for Surface Kinetics



In the **CHEMKIN Mechanism Import** dialog box:

1. Enter a name for the chemical mechanism under **Material Name**.

2. Enable **Import Surface CHEMKIN Mechanism**.

3. Enter the paths in the **Kinetic Input File** text fields in the **Gas-Phase CHEMKIN** and **Surface CHEMKIN** group boxes (for example, *path*`/chem.inp` and *path*/ *path*`/surf.inp`, respectively).

4. Specify species thermodynamic property data. You can include the data in the kinetics input file and/or in a separate file as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want to specify thermodynamic data for all species in the kinetics input file, enable **All contained in Kinetics Input File** to avoid the need to specify a separate file.
- If you provide some or all species thermodynamic data in a separate file, disable **All contained in Kinetics Input File** and specify the thermodynamic data file location.

You can either use the default thermodynamic database file, `thermo.db`, provided in the `cpropep\data` directory in your ANSYS Fluent installation area or specify the path of your thermodynamic database file if `thermo.db` does not contain all the gas-phase species in the CHEMKIN mechanism. The format for `thermo.db` is detailed in the CHEMKIN manual [52] (p. 2889).

5. To specify the surface species thermodynamic database, you can:
   - Select **All contained in Kinetics Input File** under the **Thermodynamic Database** and include the surface species thermodynamics data in the surface kinetics input file.
   - Select **Same as 'Gas-Phase CHEMKIN'** and include the surface species thermodynamics data in the thermodynamics data file used in the gas-phase mechanism. Note that the default `thermo.db` file contains only gas-phase species. If you want to use this file, you will need to supply a thermodynamic database that includes surface species defined in your simulation.

   Note

   The surface species thermodynamic data must be included either in the surface kinetics input file or in the gas-phase thermodynamics data file. If you do not import thermodynamics data as a separate file in the gas-phase CHEMKIN mechanism, then all surface thermodynamics data must be contained in the surface kinetics input file.

6. Click the **Import** button.

ANSYS Fluent will create a material with the specified name, which will contain the CHEMKIN data for the species and reactions, and add it to the list of **Fluent Mixture Materials**. You can view all of the reactions by clicking the **Edit...** button to the right of **Mechanism**, under **Properties** in the Create/Edit Materials Dialog Box (p. 2302).

ANSYS Fluent will also automatically save the imported data within the Fluent case file. Note that carrying the original input files along with the Fluent case file is not required. ANSYS Fluent will automatically retrieve these files when needed (for example, when using the CHEMKIN-CFD solver).

For details on importing gas species transport properties, see Procedure for Importing Volumetric CHEMKIN Mechanisms (p. 968).

Important

A surface reaction rate constant can be expressed in terms of a sticking coefficient in CHEMKIN mechanisms. When **Stiff Chemistry Solver** is selected from the **Chemistry Solver** drop-down list, ANSYS Fluent will convert this sticking coefficient form to an equivalent Arrhenius rate expression [51] (p. 2889). For full compatibility with ANSYS Chemkin-Pro, select **CHEMKIN-CFD Solver** instead.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.2.2.1. Compatibility and Limitations for Gas Phase Reactions

Generally, ANSYS Fluent handles all reaction types that are supported in ANSYS Chemkin-Pro. However, some limitations still exist for the following models and features:

- the density-based solver
- the **None – Explicit Source** chemistry solver (non-stiff chemistry)
- the **Finite-Rate/Eddy-Dissipation** turbulence-chemistry interaction

In these cases, only the following volume reaction types can be used:

- Arrhenius, including those reactions with arbitrary reaction order, third-body efficiencies and non-integer stoichiometric coefficients
- Pressure-dependent reactions using the Lindemann, Troe and SRI forms
- CHEMKIN mechanism files with CHEMKIN-default rate parameter units
- Duplicate reactions (keyword DUP)
- Arbitrary reverse reaction (keyword REV)

14.2.2.2. Compatibility and Limitations for Surface Reactions

As with volume reactions, ANSYS Fluent generally handles all reaction types that are supported in ANSYS Chemkin-Pro. However, limitations exist for the same models and features as described in Compatibility and Limitations for Gas Phase Reactions (p. 998). That is, with the density-based solver, **None – Explicit Source** chemistry solver, or **Finite-Rate/Eddy-Dissipation** turbulence-chemistry interaction, only the following surface reaction types can be used:

- Arrhenius reactions, including those with arbitrary reaction order, third-body efficiencies and non-integer stoichiometric coefficients
- Sticking coefficients (keyword STICK). ANSYS Fluent converts these to an equivalent Arrhenius expression.
- Arbitrary reaction units
- Duplicate reactions (keyword DUP)
- Surface coverage modification (keyword COV)

For a detailed description of the keywords, see ANSYS Chemkin-Pro Input Manual on the ANSYS Customer Portal (support.ansys.com/docdownloads).

14.2.3. Manual Inputs for Wall Surface Reactions

The basic steps for setting up a problem involving wall surface reactions are the same as those presented in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958) for setting up a problem with only fluid-phase reactions, with a few additions:

1. In the Species Model Dialog Box (p. 2216):

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Species Edit...

a. Enable **Species Transport**, select **Volumetric** and **Wall Surface** under **Reactions**, and specify the **Mixture Material**. See Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960) for details about this procedure, and Mixture Materials (p. 959) for an explanation of the mixture material concept.

b. (optional) If you want to model the heat release due to wall surface reactions, enable the **Heat of Surface Reactions** option.

c. (optional) If you want to include the effect of surface mass transfer in the continuity equation, enable the **Mass Deposition Source** option.

d. To control the robustness and the convergence speed, enter a value between 0 and 1 for the **Aggressiveness Factor**. A value of 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5.

e. (optional) If you are using the pressure-based solver and you want to include species diffusion effects in the energy equation, enable the **Diffusion Energy Source** option. See Wall Surface Mass Transfer Effects in the Energy Equation (p. 1000) for details.

f. (optional, but recommended for CVD) If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, enable the **Full Multicomponent Diffusion** or **Thermal Diffusion** option. See Full Multicomponent Diffusion (p. 520) for details.

2. Check and/or define the properties of the mixture. See Defining Properties for the Mixture and Its Constituent Species (p. 972).

   Setup → Materials

   Mixture properties include the following:

   - species in the mixture
   - reactions
   - other physical properties (for example, viscosity, specific heat)

   Important

   - You will find all species (including the solid/bulk and site species) in the list of **Fluent Fluid Materials**. For a deposited species such as Si, you will need both Si(g) and Si(s) in the materials list for the **fluid** material type.
   - Note that the *final* gas-phase species named in the **Selected Species** list should be the carrier gas. This is because ANSYS Fluent will not solve the transport equation for the final species. Note also that any reordering, adding or deleting of species should be handled with caution, as described in Reordering Species (p. 976).

3. Check and/or set the properties of the individual species in the mixture. (See Defining Properties for the Mixture and Its Constituent Species (p. 972).) Note that if you are modeling the heat of surface reactions, you should be sure to check (or define) the formation enthalpy for each species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Set species boundary conditions.

   Setup → Boundary Conditions

   In addition to the boundary conditions described in Defining Cell Zone and Boundary Conditions for Species (p. 990), you will first need to indicate whether or not surface reactions are in effect on each wall. If so, you will then need to assign a reaction mechanism to the wall. To enable the effect of surface reaction on a wall, enable the **Reaction** option in the **Species** section of the **Wall** dialog box.

   Important

   If you have enabled the global **Low-Pressure Boundary Slip** option in the Viscous Model Dialog Box (p. 2176), the **Shear Condition** for each wall will be reset to **No Slip** even though the slip model will be in effect. Note that the **Low-Pressure Boundary Slip** option is available only when the **Laminar** model is selected in the **Viscous Model** dialog box.

   See Inputs at Wall Boundaries (p. 358) for details about boundary condition inputs for walls. See User Inputs for Porous Media (p. 267) for details about boundary condition inputs for porous media.

14.2.4. Including Mass Transfer To Surfaces in Continuity

In the surface reaction boundary condition described above, the effects of the wall normal velocity or bulk mass transfer to the wall are not included in the computation of species transport. The momentum of the net surface mass flux from the surface is also ignored because the momentum flux through the surface is usually small in comparison with the momentum of the flow in the cells adjacent to the surface. However, you can include the effect of surface mass transfer in the continuity equation by activating the **Mass Deposition Source** option in the Species Model Dialog Box (p. 2216).

14.2.5. Wall Surface Mass Transfer Effects in the Energy Equation

Species diffusion effects in the energy equation due to wall surface reactions are included in the normal species diffusion term described in Treatment of Species Transport in the Energy Equation in the Theory Guide.

If you are using the pressure-based solver, you can neglect this term by disabling the **Diffusion Energy Source** option in the Species Model Dialog Box (p. 2216). For the density-based solvers, this term is always included; you cannot disable it. Neglecting the species diffusion term implies that errors may be introduced to the prediction of temperature in problems involving mixing of species with significantly different heat capacities, especially for components with a Lewis number far from unity. While the effect of species diffusion should go to zero at Le = 1, you may see subtle effects due to differences in the numerical integration in the species and energy equations.

14.2.6. Modeling the Heat Release Due to Wall Surface Reactions

The heat release due to a wall surface reaction is, by default, ignored by ANSYS Fluent. You can, however, choose to include the heat of surface reaction by activating the **Heat of Surface Reactions** option in the Species Model Dialog Box (p. 2216) and setting appropriate formation enthalpies in the Edit Material Dialog Box (p. 2355).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.2.7. Solution Procedures for Wall Surface Reactions

As in all CFD simulations, your surface reaction modeling effort may be more successful if you start with a simple problem description, adding complexity as the solution proceeds. For wall surface reactions, you can follow the same guidelines presented for fluid-phase reactions in Solution Procedures for Chemical Mixing and Finite-Rate Chemistry (p. 990).

In addition, if you are modeling the heat release due to surface reactions and you are having convergence trouble, you should try temporarily turning off the **Heat of Surface Reactions** and **Mass Deposition Source** options in the Species Model Dialog Box (p. 2216).

If you are modeling surface site species, good estimates of the **Initial Site Coverage** will aid convergence.

14.2.8. Postprocessing for Surface Reactions

In addition to the gas-phase variables listed in Postprocessing for Species Calculations (p. 994), for surface reactions you can display/report the surface coverage as well as the deposition rate of the solid species deposited on a surface. Select **Surface Coverage of species-n**, **Surface Deposition Rate of species-n**, or **Porous Deposition Rate of species-n** in the **Species...** category of the variable selection drop-down list.

Important

For surface reactions involving porous media, you can display/report the surface reaction rates using the **Kinetic Rate of Reaction-n(Porous)** in the **Reactions...** category of the variable selection drop-down list.

14.3. Particle Surface Reactions

As described in The Multiple Surface Reactions Model in the Theory Guide, it is possible to define multiple particle surface reactions to model the surface combustion of a combusting discrete-phase particle. For more information about the theoretical background of particle surface reactions, see Particle Surface Reactions in the Theory Guide. Information about using particle surface reactions is provided in the following subsections:

14.3.1. User Inputs for Particle Surface Reactions
14.3.2. Modeling Gaseous Solid Catalyzed Reactions
14.3.3. Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion

14.3.1. User Inputs for Particle Surface Reactions

The setup procedure for particle surface reactions requires only a few inputs in addition to the procedure for volumetric reactions described in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958) – Defining Other Sources of Chemical Species (p. 990). These additional inputs are as follows:

- In the **Species Model** dialog box, enable the **Particle Surface** option under **Reactions**.

Setup → **Models** → **Species** **Edit...**

- When you specify the species involved in the particle surface reaction, be sure to identify the surface species, as described in Defining Properties for the Mixture and Its Constituent Species (p. 972).

  Important

  You will find all species (including the surface species) in the list of **Fluent Fluid Materials**. If, for example, you are modeling coal gasification, you will find solid carbon, C(s), in the materials list for the **fluid** material type.

- For each particle surface reaction, select **Particle Surface** as the **Reaction Type** in the **Reactions** dialog box, and specify the following parameters (in addition to those described in Defining Reactions (p. 977)):

  Diffusion-Limited Species

  When there is more than one gaseous reactant taking part in the particle surface reaction, the diffusion-limited species is the species for which the concentration gradient between the bulk and the particle surface is the largest. See Figure 7.1: A Reacting Particle in the Multiple Surface Reactions Model in the Theory Guide for an illustration of this concept. In most cases, there is a single gas-phase reactant and the diffusion-limited species does not need to be defined.

  Catalyst Species

  This option is available only when there are no solid species defined in the stoichiometry of the particle surface reaction. In such a case, you will need to specify the solid species that acts as a catalyst for the reaction. The reaction will proceed only on the particles that contain this solid species. See Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion (p. 1002) for details on defining the particle surface species mass fractions.

  Diffusion Rate Constant

  ($C_{1,r}$ in Equation 7.71 in the Theory Guide)

  Effectiveness Factor

  (η_r in Equation 7.69 in the Theory Guide)

14.3.2. Modeling Gaseous Solid Catalyzed Reactions

The catalytic particle surface reaction option is enabled in ANSYS Fluent when **Particle Surface** is selected as the **Reaction Type** in the Reactions Dialog Box (p. 2334) and there are no solid species in the reaction stoichiometry. The solid species acting as a catalyst for the reaction is defined in the **Reactions** dialog box. The catalytic particle surface reaction will proceed only on those particles containing the catalyst species.

14.3.3. Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion

When you use the multiple surface reactions model, the procedure for setting up a problem involving a discrete phase is slightly different from that outlined in Steps for Using the Discrete Phase Models (p. 1240). The revised procedure is as follows:

1. Enable any of the discrete phase modeling options, if relevant, as described in Physical Models for the Discrete Phase Model (p. 1249).

2. Specify the initial conditions, as described in Setting Initial Conditions for the Discrete Phase (p. 1265).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Define the boundary conditions, as described in Setting Boundary Conditions for the Discrete Phase (p. 1301).

4. Define the material properties, as described in Setting Material Properties for the Discrete Phase (p. 1313).

   Important

   You must select **multiple-surface-reactions** in the **Combustion Model** drop-down list in the **Create/Edit Materials** dialog box before you can proceed to the next step.

5. If you have defined more than one particle surface species, for example, carbon (**C<s>**) and sulfur (**S<s>**), you will need to return to the **Set Injection Properties** dialog box (or **Set Multiple Injection Properties** dialog box) to specify the mass fraction of each particle surface species in the combusting particle. Click the **Multiple Reactions** tab, and enter the **Species Mass Fractions**. These mass fractions refer to the combustible fraction of the combusting particle, and should sum to 1. If there is only one surface species in the mixture material, the mass fraction of that species will be set to 1, and you will not specify anything under **Multiple Surface Reactions**.

6. Set the solution parameters and solve the problem, as described in Solution Strategies for the Discrete Phase (p. 1325).

7. Examine the results, as described in Postprocessing for the Discrete Phase (p. 1329).

   Important

   Solid deposition reactions on the particle are not allowed together with custom laws.

14.4. Electrochemical Reactions

Similar to wall surface reactions, electrochemical reactions generate sources (and sinks) in chemical species transport equations.

For more information about the theoretical background of electrochemical reactions, see Electrochemical Reactions in the *Fluent Theory Guide*. Information about using electrochemical reactions is presented in the following sections:

14.4.1. Overview of Electrochemical Reactions
14.4.2. User Inputs for Electrochemical Reactions
14.4.3. Electrochemical Reaction Effects in the Energy Equation
14.4.4. Electrochemical Reaction Effects in the Species Transport Equation
14.4.5. Including Mass Transfer in Continuity
14.4.6. Solution Procedures for Electrochemical Reactions

14.4.1. Overview of Electrochemical Reactions

An electrochemical reaction occurs only on wall surfaces where the electrolyte and the electrode meet. Both aqueous and solid species can participate in electrochemical reactions. Solid species that can be involved in electrochemical reactions are corroded or deposited species.

Electrochemical reactions can be limited so that they can only occur on some of the wall boundaries (while the other wall boundaries remain free of reaction). The reaction rate is defined and computed per unit surface area, in contrast to the fluid-phase reactions, which are based on unit volume.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can specify different reaction mechanisms for different walls. Each reaction mechanism can have multiple electrochemical reactions.

14.4.2. User Inputs for Electrochemical Reactions

The steps needed to incorporate electrochemical reactions in your problem are as follows:

1. For unsteady simulations, select **Transient** from the **Setting Up Physics** ribbon tab (**Solver** group).

2. Enable chemical species transport model.

   Setup → Models → Species **Edit...**

   Figure 14.17: The Species Model Dialog Box with Electrochemical Reactions Enabled

   a. In the **Species Model** dialog box, under **Model**, enable **Species Transport**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. Under **Reactions**, select **Volumetric** and **Electrochemical**.

> **Note**
>
> Once you enable the **Electrochemical** reactions, the electric potential solver will be automatically enabled (under the **Models** tree branch).

3. In the **Create/Edit Materials** dialog box, define all the species materials that are present in the electrolyte and electrodes.

Setup → **Materials**

a. Copy the new species from the Fluent database to your case as described in Copying Materials from the ANSYS Fluent Database (p. 464). If your species material is not present in the database, copy a similar species material and edit its properties, including **Name** and **Chemical Formula**.

> **Note**
>
> - When copying species (including corroded and deposited solid species), make sure that **fluid** is selected as **Material Type** in the **Fluent Database Materials** dialog box.
> - It is not necessary to represent the electron in the reaction, and e^- can be safely ignored.

b. Under the **Properties** group box, set **Charge Number** for the new species.

> **Important**
>
> By default, **Charge Number** is set to 0, which means that the species is neutral. Make sure to specify the **Charge Number** for all relevant species.

> **Note**
>
> Do not specify **Electrical Conductivity** for individual species. You will specify **Electrical Conductivity** for the mixture.

4. Edit the mixture composition using the **Species** dialog box (opened by clicking **Edit** next to **Mixture Species** under **Properties** of the **Create/Edit Materials** dialog box).

a. Remove unused species and add the electrochemical species to the **Selected Species** list as described in Adding Species to the Mixture (p. 975).

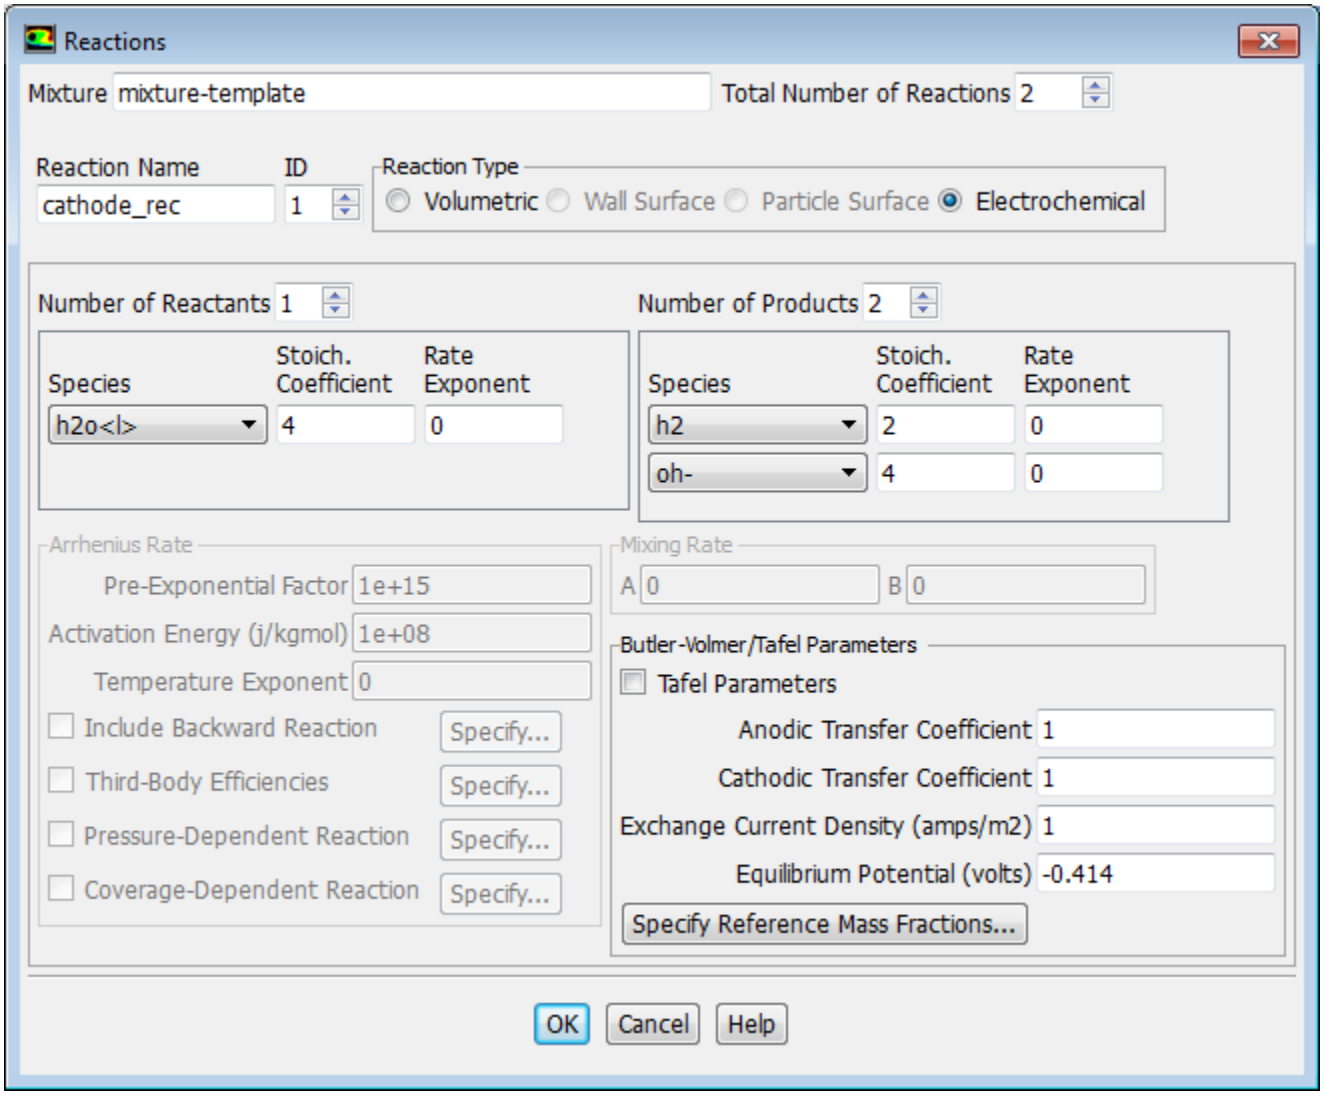
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. If solid species are involved in the electrochemical reactions (for example, in corrosion or electroplating simulations), add them to the **Selected Solid Species** list.

> **Note**
>
> Make sure that the bulk species is the last species in the **Selected Species** list. ANSYS Fluent solves transport equations for all but the last species in the **Selected Species** list. The order of the solution is the same as the order of the species in **Selected Species**.

5. Specify the reactions in the **Reactions** dialog box (opened by clicking **Edit** next to **Reactions** under **Properties** of the **Create/Edit Materials** dialog box).

Figure 14.18: The Reactions Dialog Box



For each reaction, configure the following settings:

a. Select **Electrochemical** as the reaction type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. If you want the Tafel Equation 7.81 in the *Fluent Theory Guide*, rather than the Bulter-Volmer Equation 7.80, to be used in the kinetics calculation, select **Tafel Parameters**.

c. Specify the following **Butler-Volmer/Tafel Parameters**:

- Butler-Volmer parameters (the **Tafel Parameters** check box is cleared):
  - **Anodic Transfer Coefficient** (α_a in Equation 7.80 in the *Fluent Theory Guide*)
  - **Cathodic Transfer Coefficient** (α_c in Equation 7.80 in the *Fluent Theory Guide*)
- Tafel parameters (the **Tafel Parameters** check box is selected):
  - **Anodic Tafel Slope** ($\beta_{a,r}$ in Equation 7.81 in the *Fluent Theory Guide*)
  - **Cathodic Tafel Slope** ($\beta_{c,r}$ in Equation 7.81 in the *Fluent Theory Guide*)
- **Exchange Current Density** (i_o in Equation 7.80 in the *Fluent Theory Guide*)
- **Equilibrium Potential** (E_{eq} in Equation 7.82 in the *Fluent Theory Guide*)

d. Enter the k^{th} species dimensionless power (γ_k in Equation 7.80 in the *Fluent Theory Guide*) as **Rate Exponent**.

e. Under the **Butler-Volmer/Tafel Parameters** group box, click the **Specify Reference Mass Fractions...** button and in the **Reference Mass Fractions** dialog box that opens, enter the reference species mass fractions (Y_k in Equation 7.80 in the *Fluent Theory Guide*).

Note

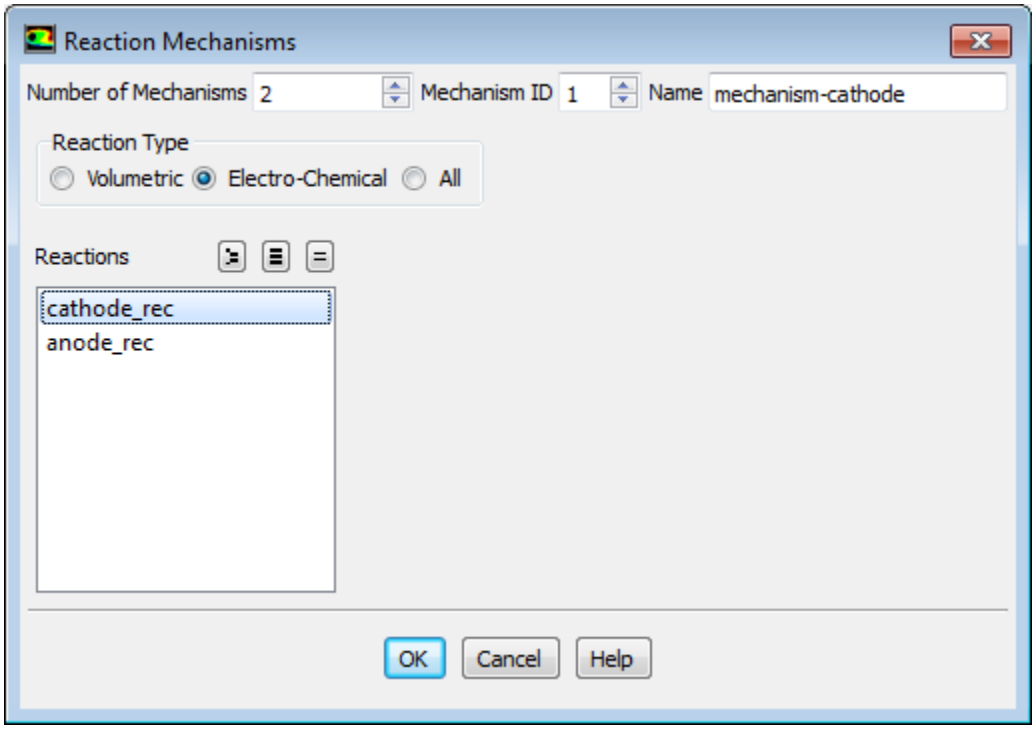
A user-defined function (UDF) hook for the electrochemical reaction rate is available as a `DEFINE_EC_RATE` function. Refer to `DEFINE_EC_RATE` in the *Fluent Customization Manual* for details about defining `DEFINE_EC_RATE` functions.

---

6. Define reaction mechanisms using the **Reaction Mechanisms** dialog box (opened by clicking **Edit** next to **Mechanism** under **Properties** of the **Create/Edit Materials** dialog box).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.19: The Reaction Mechanisms Dialog Box



a. Specify **Number of Mechanisms**. If you type in the value, be sure to press **Enter**.

b. For each electrochemical reaction mechanism, configure the following settings:

   i. Set the **Mechanism ID** of the mechanism you want to define. Again, if you type in the value, be sure to press **Enter**.

   ii. Select **Electrochemical** as a reaction type.

   iii. Under **Reactions**, select the reaction and in the **Name** text entry field, specify a meaningful name for the mechanism (for example, **`mechanism-anode`** or **`mechanism-cathode`**).

7. In the **Create/Edit Materials** dialog box, set the remaining mixture properties, such as **Density** (typically volume-weighted-mixing-law), **Mass Diffusivity**, and **Electrical Conductivity**.

   Note that if the anode, cathode, and electrolyte have different material properties, such as species mass diffusivities, it is best to use a UDF. Alternatively, you can create new materials for the anode and cathode by copying existing materials from the Fluent database, renaming them, and then assigning these materials to the anode and cathode fluid zones in the **Cell Zone Conditions** dialog box.

8. For electrolyte and electrode zones, set cell zone conditions using Cell Zone Conditions Task Page (p. 2367).

Setup → Cell Zone Conditions

a. In the **Fluid** dialog box, specify whether or not the selected zone is an electrolyte zone by selecting or clearing the **Electrolyte** check box. By default, all fluid zones are electrolyte zones.

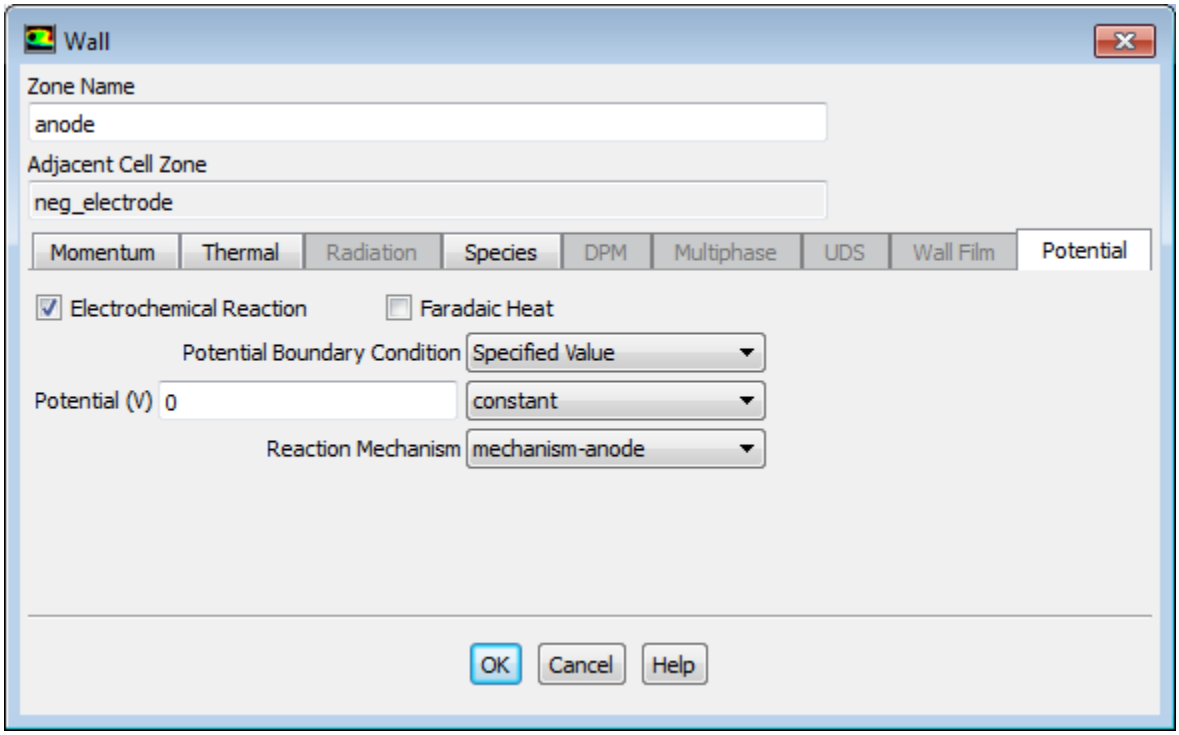
b. If there is no volumetric reactions, clear the **Reaction** check box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. Set the electrochemical boundary conditions for all relevant walls using Boundary Conditions Task Page (p. 2389).

Setup → Boundary Conditions

Figure 14.20: Wall Potential Boundary Condition



Electrochemical reaction can be defined at either exterior (1-sided) walls or interior (2-sided) walls with only one side exposed to electrolyte.

In the **Wall** dialog box, configure the following settings:

a. For exterior (1-sided) walls, set the potential boundary conditions as described in Using the Electric Potential Model (p. 1547).

b. Specify whether or not the wall is Faradaic by selecting or clearing the **Electrochemical Reaction** check box.

c. For Faradaic walls, from the **Reaction Mechanism** drop-down list, select the reaction mechanism that you have previously defined.

d. If the electrochemical reaction is defined on the wall (**Electrochemical Reaction** is selected), you can include the reaction heat in the energy equation by selecting the **Faradaic Heat** check box.

Note

For the 2-sided wall, you need to specify the potential boundary conditions only on one side of the wall. The settings you have specified will be automatically copied to the other side of the wall.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

10. (optional) You can include additional sources in the energy, continuity, and species transport equations as described in the following sections:

    - Electrochemical Reaction Effects in the Energy Equation (p. 1010)
    - Electrochemical Reaction Effects in the Species Transport Equation (p. 1011)
    - Including Mass Transfer in Continuity (p. 1011).

11. Set the solution parameters in the Solution Methods Task Page (p. 2504) and Solution Controls Task Page (p. 2508).

    In many electrochemical applications, fluid convection can be neglected, in which case the **Flow** equation should be disabled in the **Equations** control box (accessible from the Solution Controls Task Page (p. 2508)).

    Similarly, for isothermal simulations, the **Energy** equation should be disabled.

    Important

    If the potential equation has difficulty converging, you can lower the **Faradaic Interface Current** under-relaxation factor in the **Solution Controls** task page to improve stability.

12. Once the solution is converged, you can display or report the following variables that are available under the **Potential** category:

    - **Electric Potential**
    - **Electric Conductivity**
    - **Faradaic Current Density**
    - **Total Surface Corrosion Rate**
    - **Electrode Surface Potential**
    - **Current Density**
    - **Joule Heat Source**
    - **Faradaic Heat Source**
    - **Total Echem Heat Source**

    In addition, you can display

    - **Echem Reaction Rate** of each reactions (under the **Reactions** category)
    - **Surface Corrosion Rate** of each solid species on a wall (under **Species** category)

14.4.3. Electrochemical Reaction Effects in the Energy Equation

When the electrochemical reaction model is enabled, you can specify two extra sources in the energy equation:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Joule heating in the fluid and solid zones

  You can include the Joule heating in the energy equation calculation by selecting the **Include Joule Heating in Energy Equation** option in the **Electric Potential** dialog box (Using the Electric Potential Model (p. 1547)).

- Electrochemical reaction heat at Faradaic interfaces

  You can include the electrochemical reaction heat by selecting the **Faradaic Heat** option in the boundary condition dialog boxes for each reacting wall.

14.4.4. Electrochemical Reaction Effects in the Species Transport Equation

When the electrochemical reaction model is enabled, you can specify an extra source in the species transport equation for the ion-species:

- Species migration in the electric field

You can include this effect by selecting the **Species Migration** option in the Species Model Dialog Box (p. 2216).

14.4.5. Including Mass Transfer in Continuity

When a solid species (corroded or deposited) is involved in an electrochemical reaction, the solid material can enter or leave the flow domain. Usually the mass transfer of the solid species is small and can be ignored in the continuity equation. However, if you want, you can include the mass source in the continuity equation by using the following Scheme command:

```
(rpsetvar 'potential/corrosion-source-in-continuity? #t)
```

14.4.6. Solution Procedures for Electrochemical Reactions

The strongly nonlinear coupling between species and electric field can cause convergence problems. To improve the stability of the solution, you can lower the **Faradaic Interface Current** under-relaxation factor in the Solution Controls Task Page (p. 2508).

In addition, you can try temporarily disabling the **Include Joule Heating in Energy Equation** and **Faradaic Heat** options (see Electrochemical Reaction Effects in the Energy Equation (p. 1010)).

You can enable these options once the solution becomes more stable.

14.5. Species Transport Without Reactions

In addition to the volumetric and surface reactions described in the previous sections, you can also use ANSYS Fluent to solve a species mixing problem without reactions. The species transport equations that ANSYS Fluent will solve are described in Volumetric Reactions in the Theory Guide, and the procedure you will follow to set up the non-reacting species transport problem is the same as that described in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958) – Defining Other Sources of Chemical Species (p. 990), with some simplifications.

The basic steps are listed below:

1. Enable **Species Transport** in the **Species Model** dialog box and select the appropriate **Mixture Material**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Species Edit...

See Overview of User Inputs for Modeling Species Transport and Reactions (p. 958) for information about the mixture material concept, and Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960) for more details about using the **Species Model** dialog box.

2. (optional) If you want to model full multicomponent (Stefan-Maxwell) diffusion or thermal (Soret) diffusion, enable the **Full Multicomponent Diffusion** or **Thermal Diffusion** option.

3. Check and/or define the properties of the mixture and its constituent species.

   Setup → Materials

   Mixture properties include the following:

   - species in the mixture
   - other physical properties (for example, viscosity, specific heat)

   See Defining Properties for the Mixture and Its Constituent Species (p. 972) for details.

4. Set species boundary conditions, as described in Defining Cell Zone and Boundary Conditions for Species (p. 990).

No special solution procedures are usually required for a non-reacting species transport calculation. Upon completion of the calculation, you can display or report the following quantities:

- **Mass fraction of species-n**
- **Mole fraction of species-n**
- **Concentration of species-n**
- **Lam Diff Coef of species-n**
- **Eff Diff Coef of species-n**
- **Enthalpy of species-n** (pressure-based solver calculations only)
- **Relative Humidity** (when the water vapors (H_2O) is present in the species mixture material)
- **Mean Molecular Weight**
- **Liquid species mass fraction of species-n** (solidification and melting model only)

These variables are contained in the **Species...** and **Properties...** categories of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1931) for a complete list of flow variables, field functions, and their definitions. Displaying Graphics (p. 1747) and Reporting Alphanumeric Data (p. 1885) explain how to generate graphics displays and reports of data.

14.6. Reacting Channel Model

Information about using the reacting channel model is presented in the following subsections. For more information about the theoretical background, see Reacting Channel Model in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

14.6.1. Overview and Limitations of the Reacting Channel Model
14.6.2. Enabling the Reacting Channel Model
14.6.3. Boundary Conditions for Channel Walls
14.6.4. Postprocessing for Reacting Channel Model Calculations

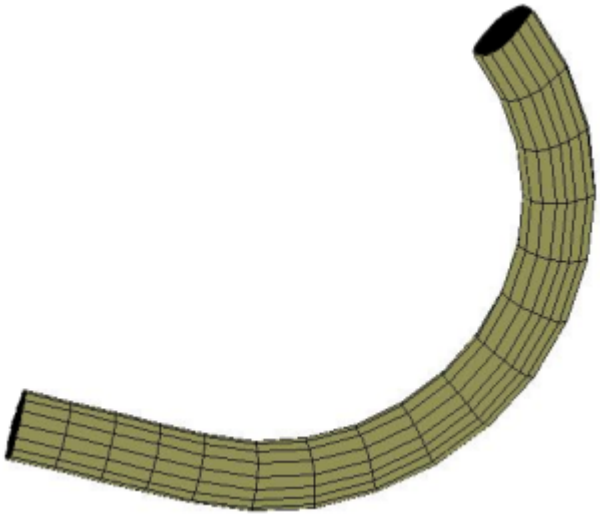
14.6.1. Overview and Limitations of the Reacting Channel Model

The reacting channel model in ANSYS Fluent offers an efficient solution methodology for solving reacting flow in shell and tube heat exchangers with long and thin channels. The volume inside the reacting channels is not meshed and solved with the outer flow. Instead, a plug flow approximation is used for the reacting channels, which is coupled to the outer flow through heat transfer across the channel walls.

The reacting channel model has the following limitations:

- The reacting channel model is available only for steady-state 3D problems.
- The reacting channel model solves the one-dimensional species equations at the centerline of the reacting channel. The accuracy of the model depends on how well ANSYS Fluent computes the channel centerline from the channel wall surface mesh. It is highly recommended to use a swept structured surface mesh on the channel wall (see Figure 14.21: Optimal Surface Mesh on the Reacting Channel Wall (p. 1013)). Unstructured channel wall surface meshes may result in loss of accuracy due to inconsistent channel centerlines.

Figure 14.21: Optimal Surface Mesh on the Reacting Channel Wall



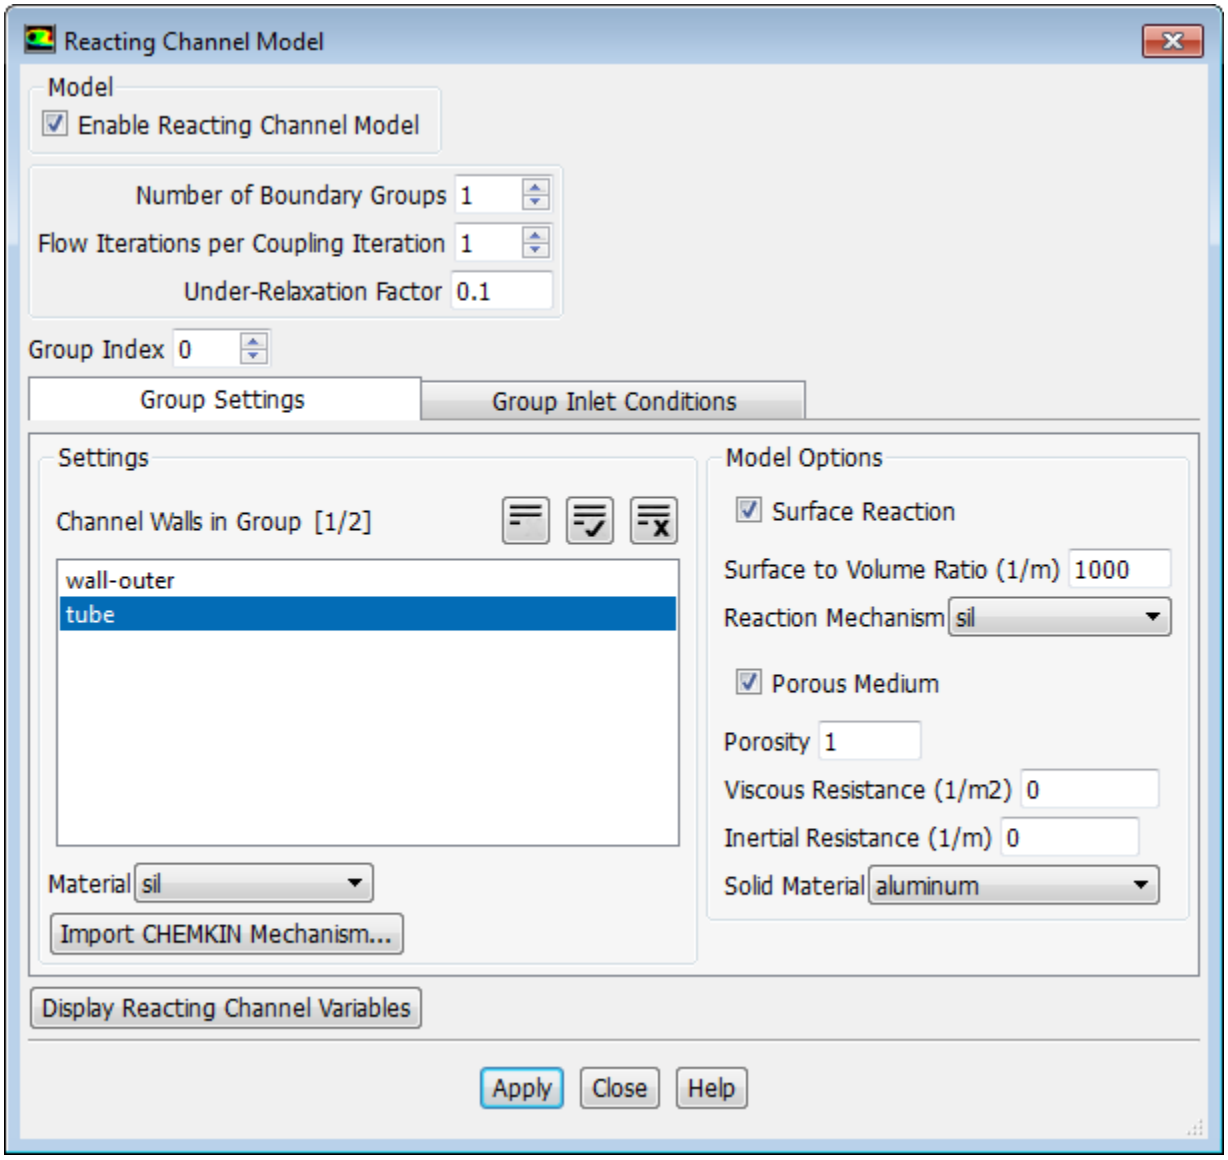
14.6.2. Enabling the Reacting Channel Model

The steps and procedure to set up a reacting channel model are outlined below. In this section, the steps pertinent to the reacting channel model only are explained. The setting up of other models used in conjunction with reacting channel models are explained in other sections of the User's Guide.

1. Enable the reacting channel model.

Setup → Models → Reacting Channel Model → Edit...

Figure 14.22: The Reacting Channel Model Dialog Box



When you enable the **Enable Reacting Channel Model** option, the dialog box will expand to show the relevant inputs (see Figure 14.22: The Reacting Channel Model Dialog Box (p. 1014)).

2. Specify the **Number of Boundary Groups**. If you have multiple channels, you can group together channels with common flow direction, mixture materials, inlet compositions, temperature, pressure, and mass flow rate. You will be required to provide the inputs for each boundary group.

> **Note**
>
> If you have multiple tubes, you will need to define each tube as a different wall and set up the model by grouping the walls together if they have the same boundary conditions.

3. Enter the number of **Flow Iterations Per Coupling Iteration**. This is the number of outer flow iterations for each channel flow iteration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Optionally change an **Under-Relaxation Factor**. The value of the under-relaxation factor is used to update the heat flux from the reacting channel. See Equation 7.107 in the Theory Guide.

5. Set the **Group Index**. Note that the **Group Index** for the first boundary group is set to `0`.

   The inputs for each boundary group are entered in the **Group Settings** and **Group Inlet Conditions** tabs as further described.

6. Under the **Group Settings** tab, specify the model settings and options. (see Figure 14.23: The Reacting Channel Model Dialog Box (Group Inlet Conditions Tab) (p. 1016)).

   a. In the **Channel Walls in Group** selection list, select the wall boundary zones that correspond to the reacting channels.

   b. Select the group material from the **Material** drop-down list. You can choose any mixture material available in the case as a group material.

   c. Optionally, import a CHEMKIN mechanism using **Import CHEMKIN Mechanism...** button. For details see Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967).

   d. To model surface reactions within the channel, enable **Surface Reactions** under **Model Options** group box. The dialog box will expand to show the related inputs as shown in Figure 14.22: The Reacting Channel Model Dialog Box (p. 1014). These inputs include:

      - **Surface to Volume Ratio** of the channel group
      - Surface reaction mechanism of the group (selected from the **Reaction Mechanism** drop-down list)

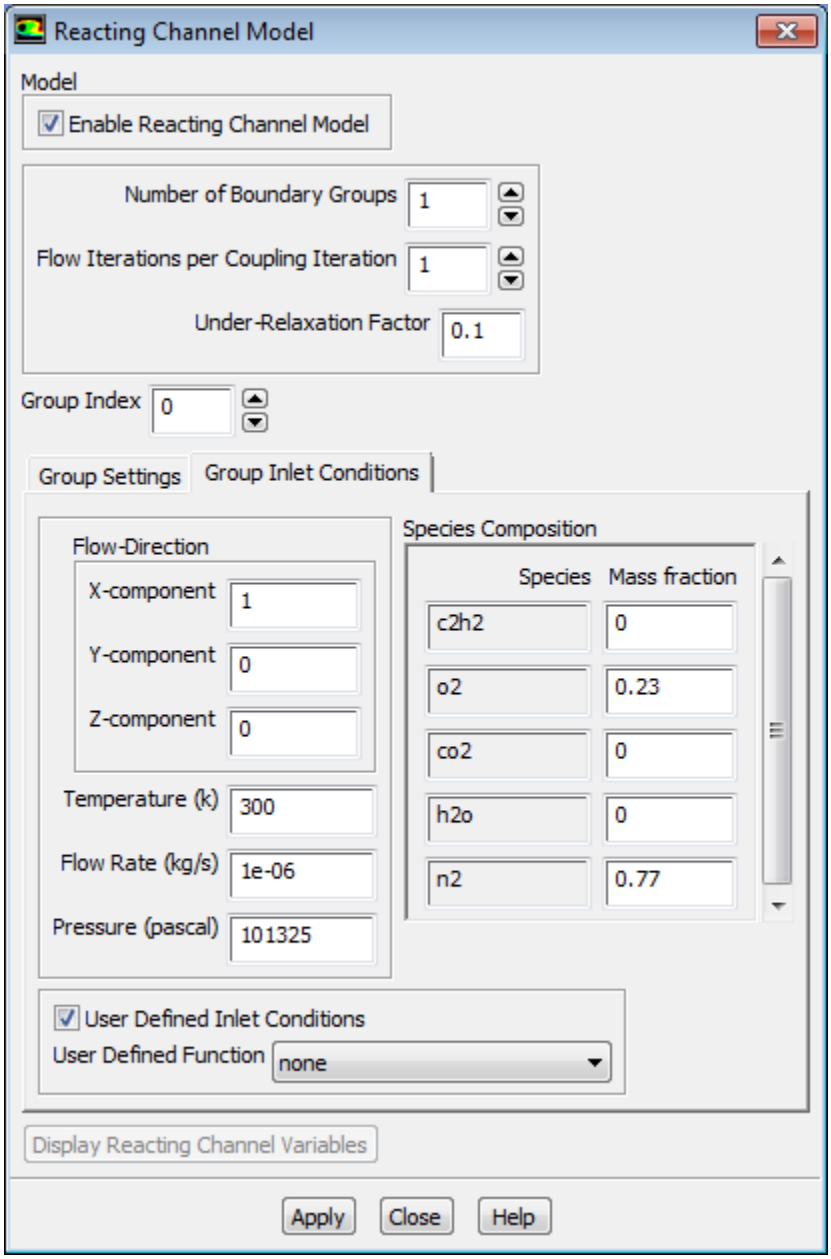
   e. To model porous medium, enable **Porous Medium** under **Model Options** group box. The dialog box will expand to show porous medium inputs as shown in Figure 14.22: The Reacting Channel Model Dialog Box (p. 1014). These inputs include:

      - **Porosity** of the channel
      - **Viscous Resistance** in axial direction of the channel
      - **Inertial Resistance** in axial direction of the channel
      - Solid material of the porous medium inside the channel (selected from the **Solid Material** drop-down list)

7. Under the **Group Inlet Conditions** tab, specify the inlet conditions for the boundary group (see Figure 14.23: The Reacting Channel Model Dialog Box (Group Inlet Conditions Tab) (p. 1016)). You can specify the inlet condition parameters as constant values. ANSYS Fluent provides you also with the option of redefining any or all of the inlet condition parameters using user-defined functions (UDFs).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.23: The Reacting Channel Model Dialog Box (Group Inlet Conditions Tab)



a. Specify the **X-**, **Y-**, and **Z-component** of the flow at the inlets of the channels in the current group in the **Flow Direction** group box.

Note

Since there is no surface or zone to identify the channel inlet or outlet, the inlet flow direction of the group is used to determine the channel inlet. Therefore, It is very important to specify the flow direction correctly.

---

b. Enter the inlet channel **Temperature**, **Flow Rate** and **Pressure** in the group.

c. Specify the inlet mass fractions for each species in the group in the **Species Composition** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

d. To specify an inlet condition using a user-defined function (UDF), select the **User Defined Inlet Conditions** check box and then select the appropriate user-defined function from the drop-down list. For information about specifying and hooking DEFINE_REACTING_CHANNEL_BC UDFs, see `DEFINE_REACTING_CHANNEL_BC` in the *Fluent Customization Manual*.

8. Click the **Apply** button to save the settings.

9. If you specified more than one boundary group in step 1, change the group ID value in **Group Index** integer number entry box and repeat steps 5–7 for each remaining boundary group.

Once the reacting channel model is defined, you can generate reports or plots of reacting channel variables using the **Reacting channel 2D Curves** dialog box (Figure 14.25: Reacting Channel 2D Curves Dialog Box (Plot) (p. 1019)). You can open the **Reacting channel 2D Curves** dialog box by clicking the **Display Reacting Channel Variables** button in the **Reacting Channel Model** dialog box. For information about the plotting of reacting channel model variables, see Postprocessing for Reacting Channel Model Calculations (p. 1018).

Modeling Curvilinear Reacting Channels

In the reacting channel model, the two ends of a channel are identified as the inlet and the outlet based on the inputs provided for the inlet flow direction of the group. However, for some special channel configurations, such as U-tubes, it is not possible to identify the inlet/outlet of the channel based on the information of the inlet flow direction. For such cases, an additional input is required to differentiate between the end points of the channel as inlet or outlet. The additional input is to provide the centroid coordinates of the inlet of the U shaped channel. Therefore, for U-tube configurations, after setting up the reacting channel model following the earlier steps in this section, it is required to use the following text user interface commands to set the inlet and outlets correctly:

```
/define/models/species> reacting-channel-model-options
Are any of the channels a U-tube configuration? [no] yes
Is wall tube1 a U-tube configuration? [no] yes
Enter the coordinates of the center of the inlet for wall tube1
X coordinate [0] 0.01
Y coordinate [0] 0
Z coordinate [0] 0
```

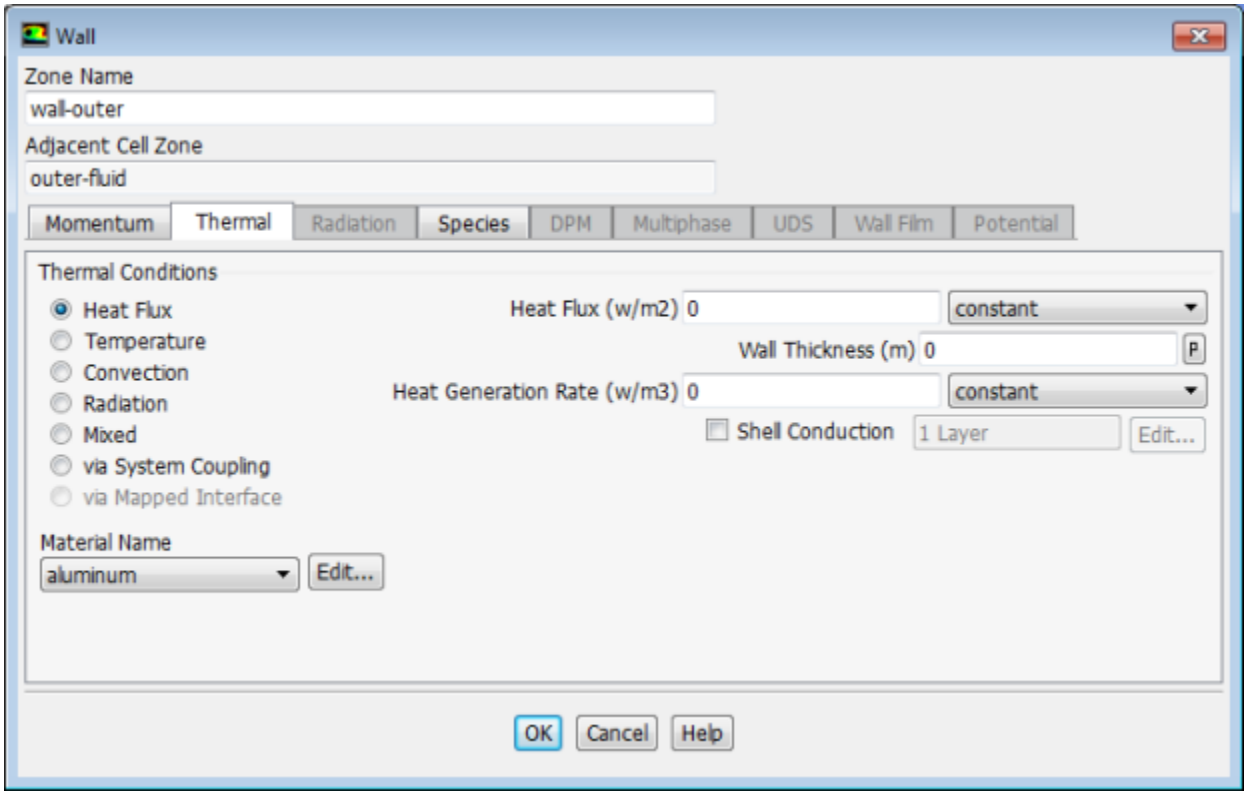
Where `tube1` is a reacting channel wall having a U shape. You will be asked the same questions for each of the existing reacting channel walls.

14.6.3. Boundary Conditions for Channel Walls

In the ANSYS Fluent wall boundary conditions dialog box, the wall surfaces that you selected as channel walls in the **Reacting Channel Model** dialog box will have zero heat flux boundary conditions, which are disabled as shown in Wall Surface Reactions and Chemical Vapor Deposition (p. 995)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.24: The Wall Boundary Condition Dialog Box for the Reacting Channel Model



The heat flux at the channel walls is calculated internally through the coupling of the reacting channel model with the outer flow as described in Reacting Channel Model in the Theory Guide. For all other wall surfaces, which are not channel walls, all boundary conditions as described in Wall Boundary Conditions (p. 358) are applicable.

14.6.4. Postprocessing for Reacting Channel Model Calculations

ANSYS Fluent provides postprocessing options for plotting and reporting channel variables using the **Reacting Channel 2D Curves** dialog box. You can generate X-Y plots or reports of the following reacting channel variables:

- Bulk mean temperature of the channel
- Wall temperature of the channel
- Nusselt Number (for the channel wall on the channel side)
- Wall heat flux through the channel walls
- Velocity inside the channel
- Density of the channel
- Mass fraction of the species inside the channel
- The surface coverage and the deposition rate of the surface species.

The steps for generating the plots/reports are as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select either **Plot Reacting Channel Variables** or **Report Reacting Channel Outlet Average**.

   The **Reacting Channel 2D Curves** dialog box displays either the **Variable Name** drop-down list for selecting a single species for X-Y plot generation, or the **Variable Names** selection list for selecting multiple species for report generation as shown in Figure 14.25: Reacting Channel 2D Curves Dialog Box (Plot) (p. 1019) and Figure 14.26: Reacting Channel 2D Curves Dialog Box (Report) (p. 1020).

Figure 14.25: Reacting Channel 2D Curves Dialog Box (Plot)

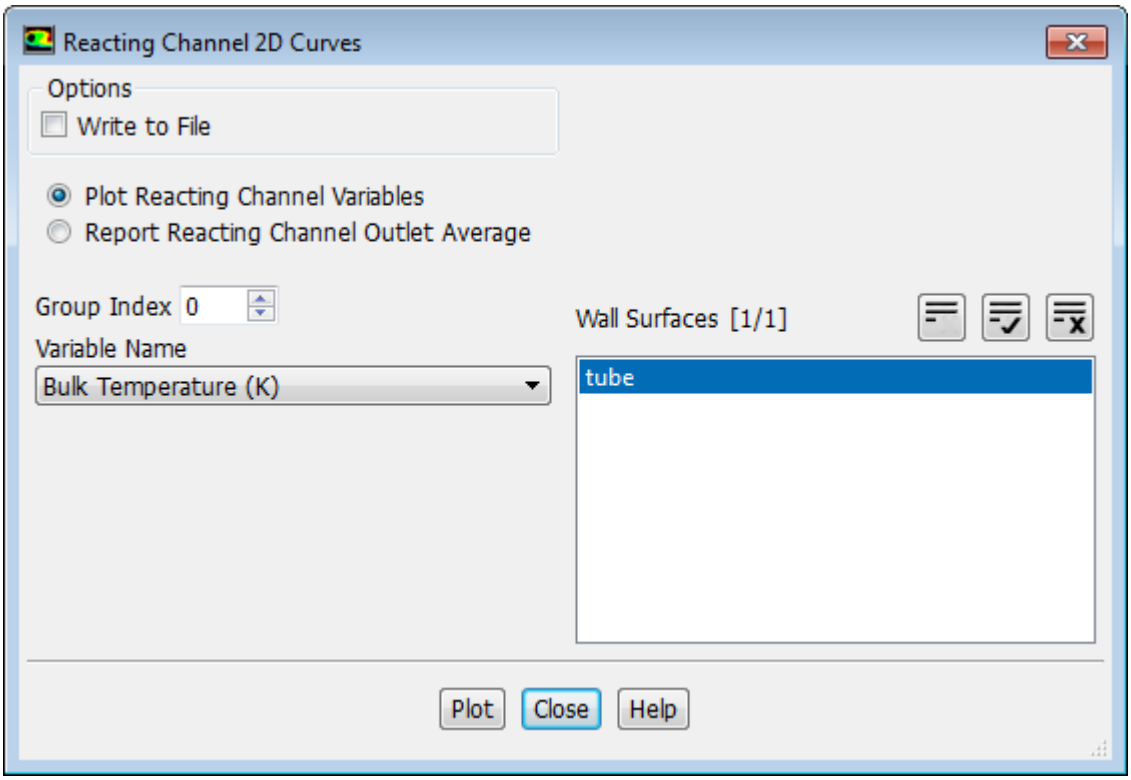


Figure 14.26: Reacting Channel 2D Curves Dialog Box (Report)

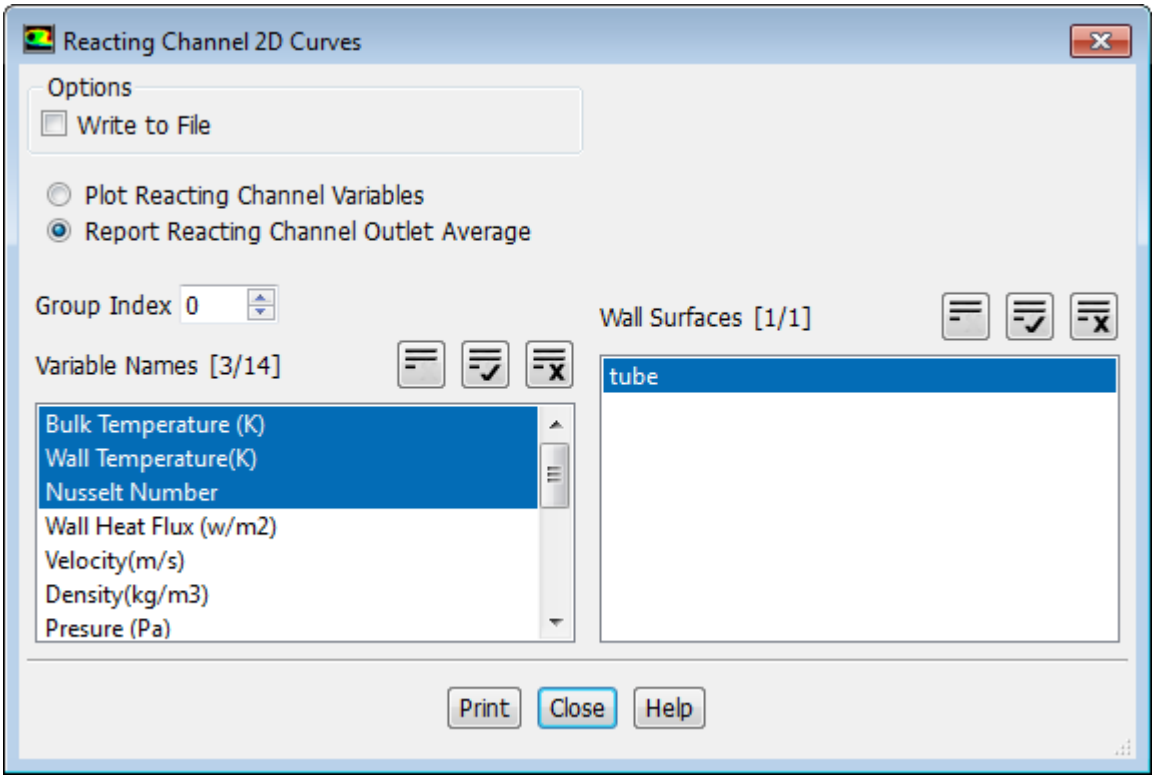


2. Specify whether you want to write the plot data to a file by using the **Write To File** check box.

3. If more than one boundary group is defined for reacting channel model, specify the group ID in the **Group Index** integer number entry box.

4. The **Variable Name** drop-down/**Variable Names** selection list contains reacting channel variables of the specified boundary group. Select the reacting channel variable(s) from the list.

5. Select the wall surface(s) from the **Wall Surfaces** selection list on which the plot/report will be generated (at least one wall surface must be selected).

6. Click one of the following as applicable:

   - **Plot** to view X-Y plot in the graphics window
   - **Print** to view report in the console window
   - **Write...** to save to file

14.7. Reactor Network Model

Information about using the Reactor Network model is presented in the following subsections.

14.7.1. Overview and Limitations of the Reactor Network Model
14.7.2. Solving Reactor Networks
14.7.3. Postprocessing Reactor Network Calculations

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For more information about the theoretical background, see Reactor Network Model in the *Fluent Theory Guide*.

14.7.1. Overview and Limitations of the Reactor Network Model

The Reactor Network model allows rapid solution of combustors using detailed chemical kinetic mechanisms. This speed is achieved by first performing a Fluent CFD simulation with a fast chemistry model, such as a Non-Premixed, Partially-Premixed, or Eddy-Dissipation model, and then using the Reactor Network model to solve with a detailed kinetic mechanism. The Reactor Network model agglomerates cells from the CFD solution into a user-specified small number of reactors and computes detailed chemistry on this reactor network.

Since the chemical kinetics is decoupled from the flow, reactor network simulations are applicable to steady simulations where the chemical kinetics does not affect the flow significantly, such as pollutant formation. Inherently unsteady simulations, such as ignition and global extinction, cannot be modeled with reactor networks. Note that the Reactor Network model can be used for unsteady simulations of statistically steady flows, such as LES, where the time-averaged flow and species fields are used to construct the reactor network.

14.7.2. Solving Reactor Networks

The steps and procedure for setting up and solving a Reactor Network model are outlined below.

1. Enable the Reactor Network model.

   Setup → **Models** → **Species** → **Reactor Network** **Edit...**

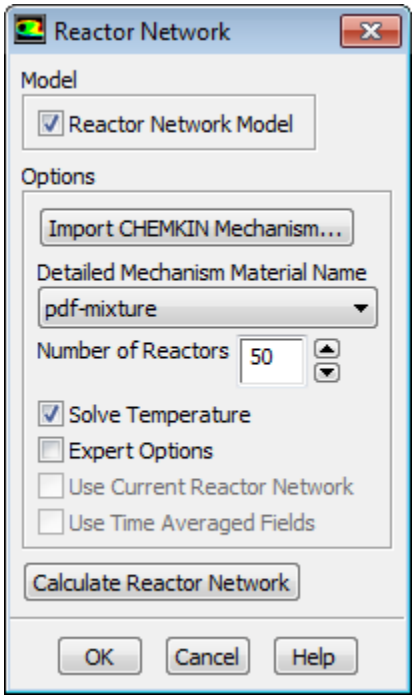
   Important

   Note that this model is only available when one of the reacting species models is enabled.

   When you select the **Reactor Network Model** option, the dialog box expands to show the relevant modeling controls (see Figure 14.27: Reactor Network Dialog Box (Steady-State Flow) (p. 1022)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 14.27: Reactor Network Dialog Box (Steady-State Flow)



2. If a detailed chemical mechanism has already been imported, select the mixture material from the **Detailed Mechanism Material Name** drop-down list. Otherwise import a mechanism in CHEMKIN format by clicking **Import CHEMKIN Mechanism...**. The mechanism files are imported into your case using the **CHEMKIN Mechanism Import** dialog box as described in Specifying a Chemical Mechanism File for Flamelet Generation (p. 1037).

3. Set the **Number of Reactors** in the reactor network. The default value of 50 is a good starting value, but it can be increased for greater accuracy.

4. Specify whether or not the temperature is calculated from the equation of state by selecting or clearing the **Solve Temperature** check box. By default, this option is selected, and ANSYS Fluent will determine the temperatures in the reactor network.

5. Once cells are agglomerated and a reactor-network solution is calculated, you can select the **Use Current Reactor Network** option to perform further reactor network simulations with the existing network of connected reactors. This option can be used to continue iterations from the previous reactor- network solution if additional convergence is desired. The option also allows you to change the chemical mechanism or species boundary conditions to generate a new solution on the current reactor network.

6. (for transient analysis with the **Data Sampling For Time Statistics** option selected in the **Run Calculation** task page only) Specify whether or not you want to use the time-averaged composition fields to agglomerate the reactors and time-averaged velocity fields to calculate the reactor mass flux matrix (instead of the instantaneous fields) by selecting or clearing the **Use Time Averaged Fields** option.

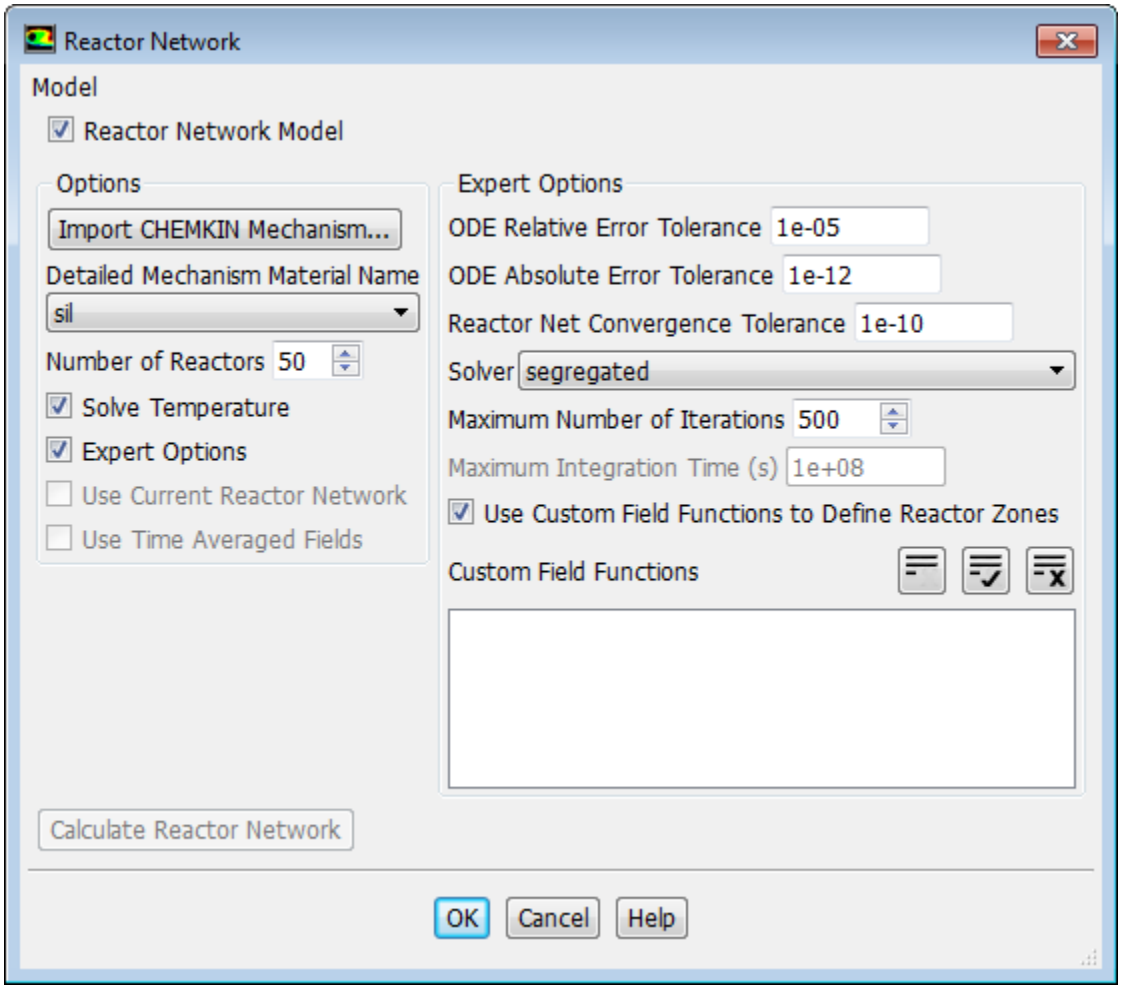
Note

The **Use Time Averaged Fields** option should be used for unsteady simulations (for example, LES) of statistically stationary combustors.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. If necessary, specify custom-field functions and adjust the default solver settings using the **Expert Options** control. When **Expert Options** is selected, the **Reactor Network** dialog box expands to reveal the following advanced options:

Figure 14.28: Reactor Network Dialog Box - Expert Options



ODE Relative Error Tolerance, ODE Absolute Error Tolerance

The default values for the ODE relative and absolute error tolerances are 1e-05 and 1e-12, respectively. If the ODE solver fails to converge, it is often helpful to lower the **ODE Relative Error Tolerance** and the **ODE Absolute Error Tolerance**.

Reactor Network Convergence Tolerance

The default value for the reactor network convergence tolerance is 1e-08. Residuals should be well converged at the default tolerance. Higher tolerances may be acceptable for engineering accuracy.

Solver

The default segregated solver typically converges faster than the coupled solver. However, when using the segregated solver, residuals may stall above an acceptable tolerance. In this case, the coupled solver should be used.

Maximum Number of Iterations (segregated solver)

If residuals are still decreasing and better convergence is desired, increase the maximum number of iterations. If residuals are stalled and a quicker exit from the solver is desired, decrease the maximum number of iterations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum Integration Time (coupled solver)
The ODE solver terminates the calculation at this time if residuals fail to converge.

Use Custom Field Functions to Define Reactor Zones
When selected, this option allows you to use custom field functions (Custom Field Functions (p. 2003)) as composition variables to create the reactor volumes. ANSYS Fluent clusters CFD cells that have similar compositions using the following default composition variables:

- temperature and mixture fraction for Non-Premixed and Partially-Premixed cases
- temperature and mass fractions of N_2 and H_2O for Species Transport cases

You can override these default composition variables by selecting **Use Custom Field Functions to Define Reactor Zones** and then selecting up to four custom field functions from the **Custom Field Functions** selection list. ANSYS Fluent will group CFD cells that are close in these custom field function composition variables. In the example shown in Figure 14.28: Reactor Network Dialog Box - Expert Options (p. 1023), cells with similar turbulent kinetic energy, x coordinate, and y coordinate will be agglomerated to form the reactor network.

8. Click **Calculate Reactor Network** to obtain a flow solution.

   As the calculation is progressing, ANSYS Fluent prints the reactor network residuals for each iteration in the console.

   Note

   The reactor network solution should converge with the default settings. However, if the model fails to converge with sufficient accuracy, you can adjust the default reactor network solver settings by using the **Expert Options** control.

14.7.3. Postprocessing Reactor Network Calculations

ANSYS Fluent provides additional postprocessing options for reactor network calculations. The following reactor network variables are available for generating graphical plots:

- **Reactor Net Zone ID**
- **Reactor Net Temperature**
- **Reactor Net Mass fraction of species-n**

These variables will appear under the **Reactor Network...** postprocessing category of the variable selection drop-down lists.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 15: Modeling Non-Premixed Combustion

In non-premixed combustion, fuel and oxidizer enter the reaction zone in distinct streams. This is in contrast to premixed systems, in which reactants are mixed at the molecular level before burning. Examples of non-premixed combustion include pulverized coal furnaces, diesel internal-combustion engines and pool fires.

Under certain assumptions, the thermochemistry can be reduced to a single parameter: the mixture fraction. The mixture fraction, denoted by f, is the atomic mass fraction that originated from the fuel stream. That is, it is the local mass fraction of burnt and unburnt fuel stream elements (C, H, and so on) in all the species (CO_2, H_2O, O_2, and so on). The approach is elegant because atomic elements are conserved in chemical reactions. In turn, the mixture fraction is a conserved scalar quantity, and therefore its governing transport equation does not have a source term. Combustion is simplified to a mixing problem, and the difficulties associated with closing nonlinear mean reaction rates are avoided. Once mixed, the chemistry can be modeled as being in chemical equilibrium with the **Chemical Equilibrium** model, being near chemical equilibrium with the **Steady Diffusion Flamelet** model, or significantly departing from chemical equilibrium with the **Unsteady Diffusion Flamelet** model.

The non-premixed combustion model is presented in the following sections:

15.1. Steps in Using the Non-Premixed Model
15.2. Setting Up the Equilibrium Chemistry Model
15.3. Setting Up the Steady and Unsteady Diffusion Flamelet Models
15.4. Defining the Stream Compositions
15.5. Setting Up Control Parameters
15.6. Calculating the Flamelets
15.7. Calculating the Look-Up Tables
15.8. Standard Files for Diffusion Flamelet Modeling
15.9. Setting Up the Inert Model
15.10. Defining Non-Premixed Boundary Conditions
15.11. Defining Non-Premixed Physical Properties
15.12. Solution Strategies for Non-Premixed Modeling
15.13. Postprocessing the Non-Premixed Model Results

For theoretical background on the non-premixed combustion model, see Non-Premixed Combustion in the Theory Guide.

15.1. Steps in Using the Non-Premixed Model

A description of the inputs for the non-premixed model is provided in the sections that follow.

15.1.1. Preliminaries
15.1.2. Defining the Problem Type
15.1.3. Overview of the Problem Setup Procedure

15.1.1. Preliminaries

Before turning on the non-premixed combustion model, you must enable turbulence calculations in the Viscous Model Dialog Box (p. 2176).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Viscous Edit...

If your model is non-adiabatic, you should also enable heat transfer (and radiation, if required).

Setup → Models → Energy ON

Setup → Models → Radiation Edit...

Figure 8.7: Reacting Systems Requiring Non-Adiabatic Non-Premixed Model Approach in the Theory Guide illustrates the types of problems that must be treated as non-adiabatic.

15.1.2. Defining the Problem Type

Your first task is to define the type of reaction system and reaction model that you intend to use. This includes selection of the following options:

- Non-premixed or partially premixed model option (see Modeling Partially Premixed Combustion (p. 1099)).
- Equilibrium chemistry model, steady diffusion flamelet model, unsteady diffusion flamelet model, or diesel unsteady flamelet.
- Adiabatic or non-adiabatic modeling options (see Non-Adiabatic Extensions of the Non-Premixed Model in the Theory Guide).
- Addition of a secondary stream (equilibrium model only).
- Empirically defined fuel and/or secondary stream composition (equilibrium model only).

You can make these model selections using the **Species Model** dialog box (Figure 15.6: The Species Model Dialog Box (Chemistry Tab) (p. 1032)).

Setup → Models → Species Edit...

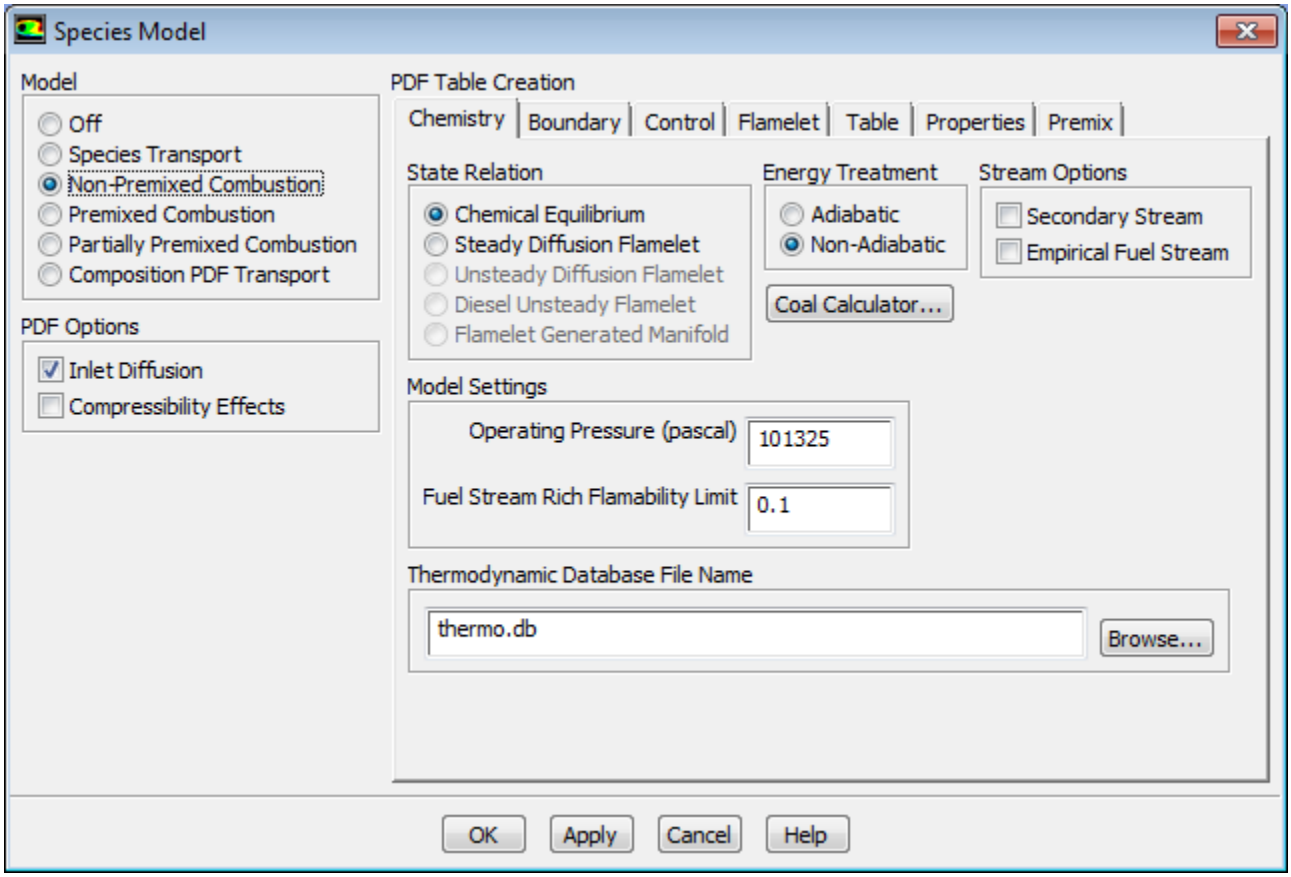
15.1.3. Overview of the Problem Setup Procedure

For a single-mixture-fraction problem, you will perform the following steps:

1. Choose the chemical description of the system: chemical equilibrium, steady diffusion flamelet, unsteady diffusion flamelet, or diesel unsteady flamelet (Figure 15.1: Defining Equilibrium Chemistry (p. 1027)).
2. Indicate whether the problem is adiabatic or non-adiabatic.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

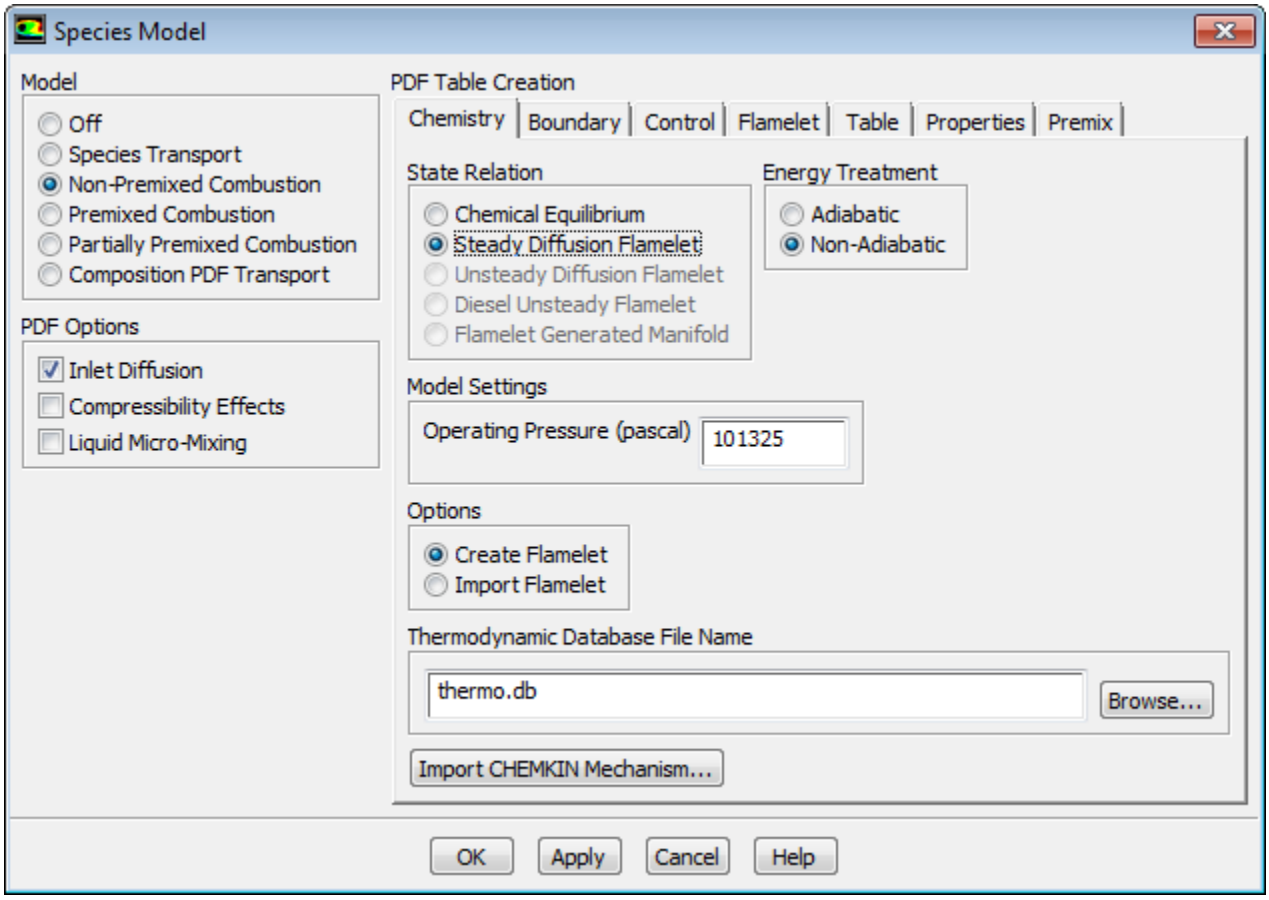
Figure 15.1: Defining Equilibrium Chemistry



3. (steady diffusion flamelet model only) Import a flamelet file or appropriate CHEMKIN mechanism file if generating flamelets (Figure 15.2: Defining Steady Diffusion Flamelet Chemistry (p. 1028)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

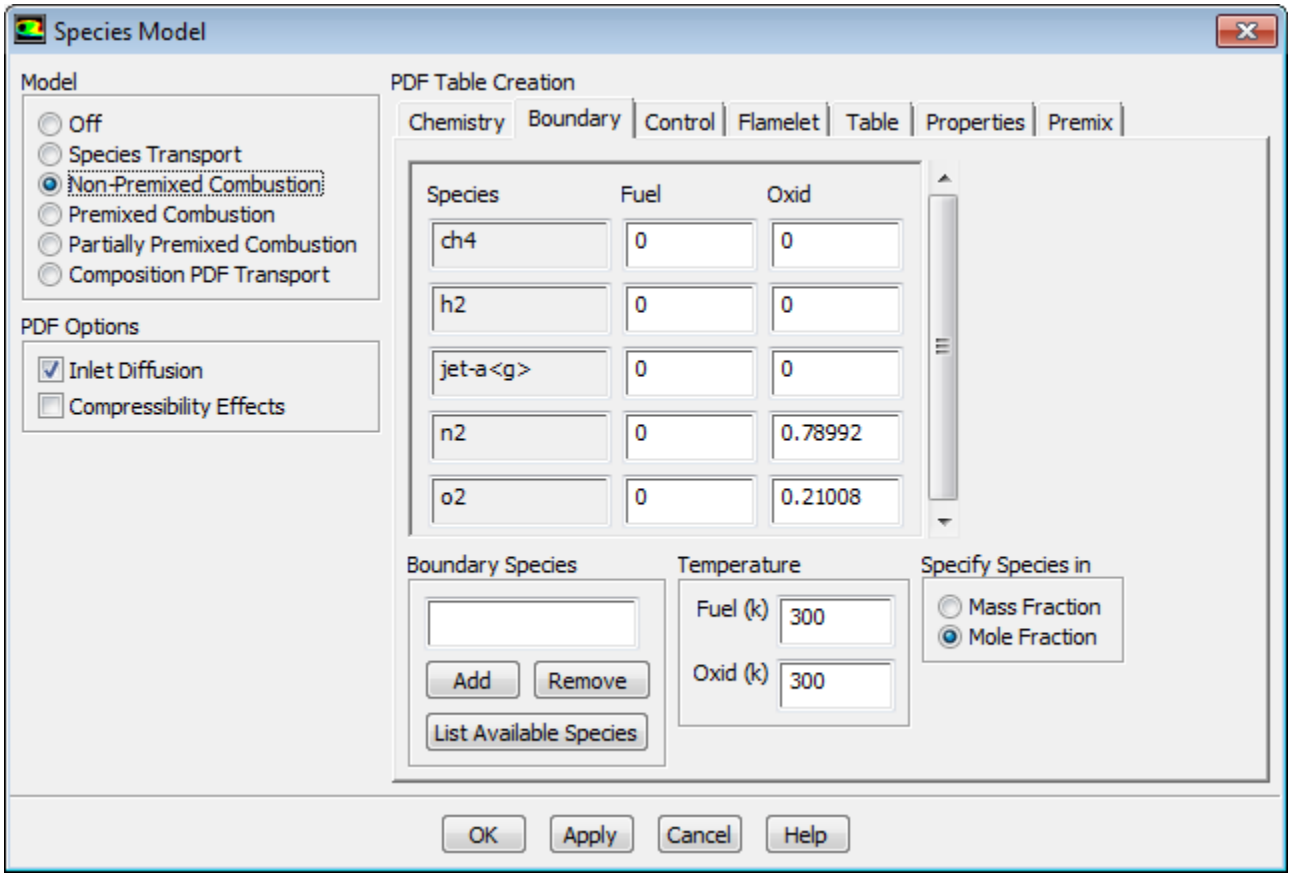
Figure 15.2: Defining Steady Diffusion Flamelet Chemistry



4. Define the chemical boundary species to be considered for the streams in the reacting system model. Note that this step is not relevant in the case of flamelet import (Figure 15.3: Defining Chemical Boundary Species (p. 1029)). For more information, see Defining the Stream Compositions (p. 1042).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

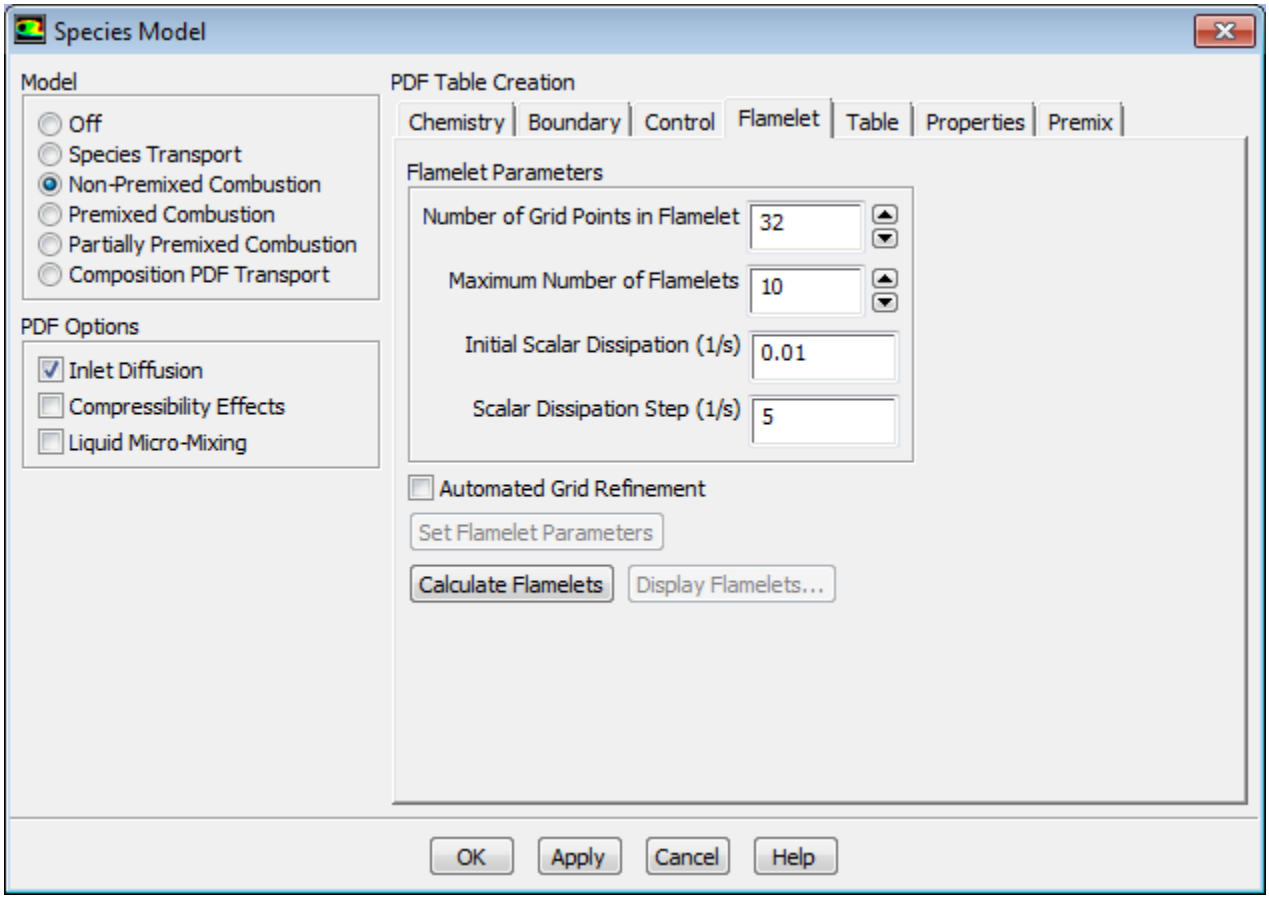
Figure 15.3: Defining Chemical Boundary Species



5. (steady diffusion flamelet model only) If you are generating flamelets, compute the flamelet state relationships of species mass fractions, density, and temperature as a function of mixture fraction and scalar dissipation (Figure 15.4: Calculating Steady Diffusion Flamelets (p. 1030)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

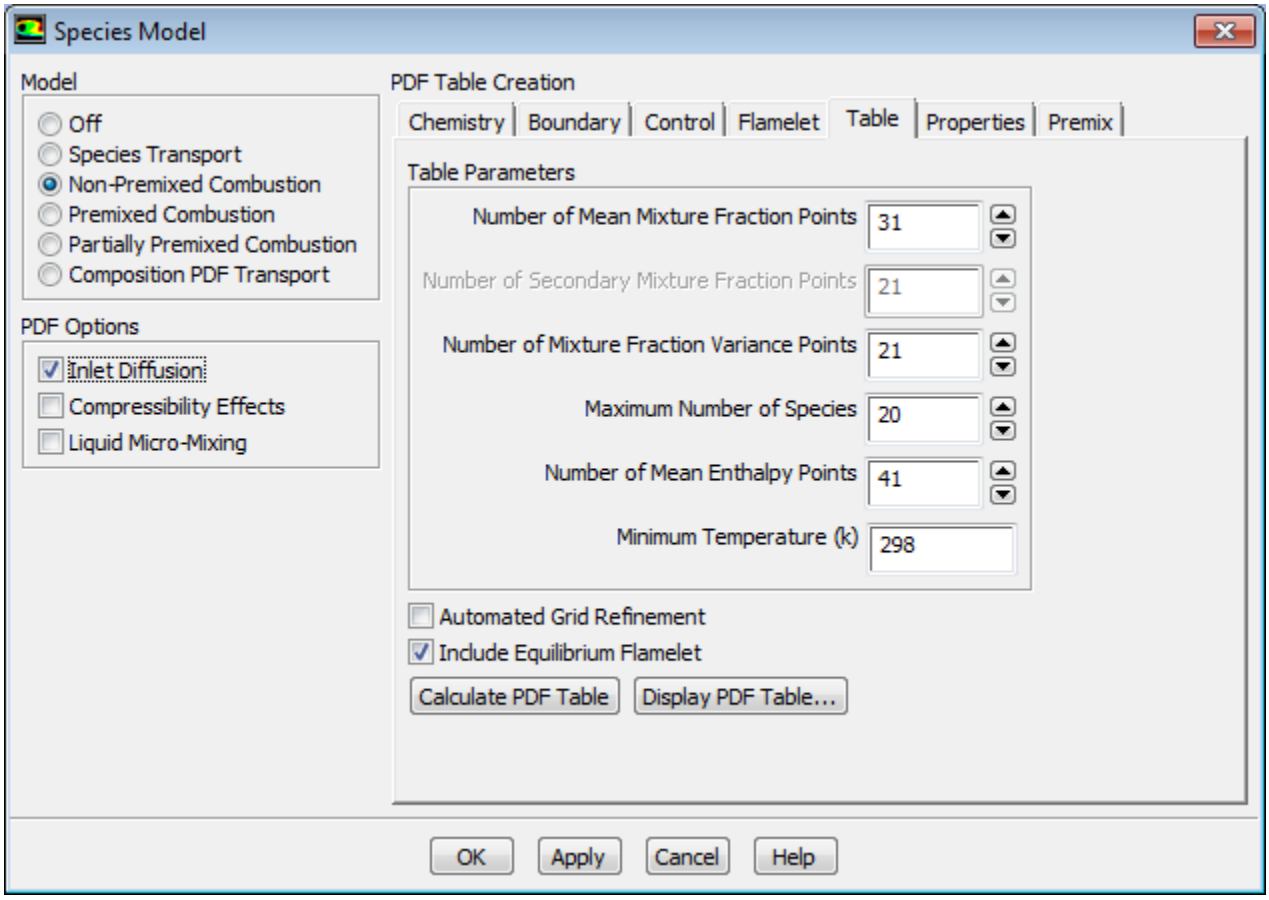
Figure 15.4: Calculating Steady Diffusion Flamelets



6. Compute the final chemistry look-up table, containing mean values of species fractions, density, and temperature as a function of mean mixture fraction, mixture fraction variance, and possibly enthalpy and scalar dissipation. The contents of this look-up table will reflect your preceding inputs describing the turbulent reacting system (Figure 15.5: Calculating the Chemistry Look-Up Table (p. 1031)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.5: Calculating the Chemistry Look-Up Table



The look-up table is the stored result of the integration of Equation 8.16 (or Equation 8.24) and Equation 8.18 (in the Theory Guide). The look-up table will be used in ANSYS Fluent to determine mean species mass fractions, density, and temperature from the values of mean mixture fraction ($\overline{f}$), mixture fraction variance ($\overline{f'^2}$), and possibly mean enthalpy ($\overline{H}$) and mean scalar dissipation ($\overline{\chi}$) as they are computed during the ANSYS Fluent calculation of the reacting flow. See Look-Up Tables for Adiabatic Systems and Figure 8.8: Visual Representation of a Look-Up Table for the Scalar (Mean Value of Mass Fractions, Density, or Temperature) as a Function of Mean Mixture Fraction and Mixture Fraction Variance in Adiabatic Single-Mixture-Fraction Systems and Figure 8.10: Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems in the Theory Guide.

For a problem that includes a secondary stream (and, therefore, a second mixture fraction), you will perform the first two steps listed above for the single-mixture-fraction approach and then prepare a look-up table of instantaneous properties using Equation 8.12 or Equation 8.14 in the Theory Guide.

15.2. Setting Up the Equilibrium Chemistry Model

In the equilibrium chemistry model, the concentrations of species of interest are determined from the mixture fraction using the assumption of chemical equilibrium (see Non-Premixed Combustion and Mixture Fraction Theory in the Theory Guide). With this model, you can include the effects of intermediate species and dissociation reactions, producing more realistic predictions of flame temperatures than the Eddy-Dissipation model. When you choose the equilibrium chemistry option, you will have the opportunity to use the rich flammability limit (RFL) option.

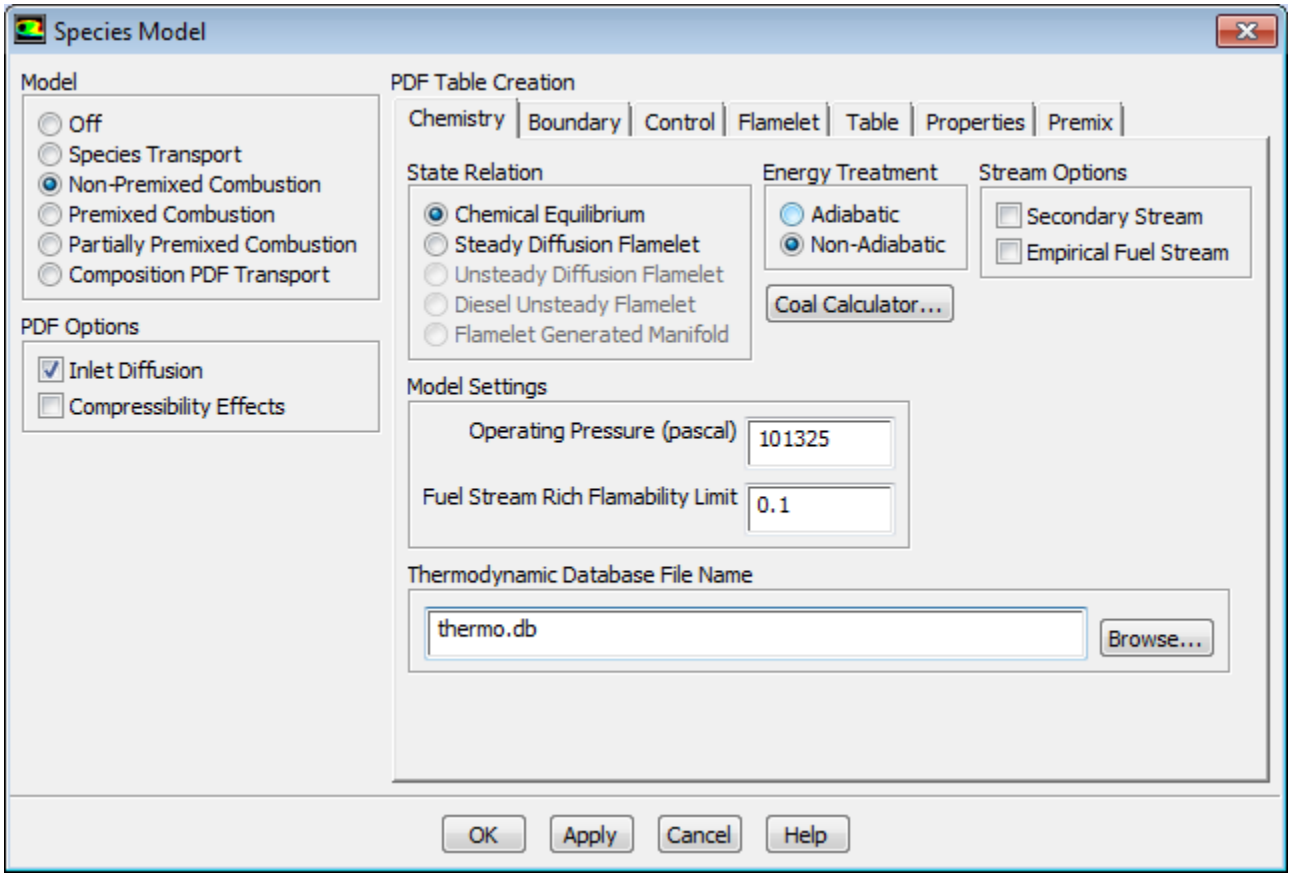
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To enable the equilibrium chemistry model

1. Select **Non-Premixed Combustion** in the **Species Model** dialog box.

2. Select **Chemical Equilibrium** in the **Chemistry** tab of the **Species Model** dialog box.

Figure 15.6: The Species Model Dialog Box (Chemistry Tab)



For additional information, see the following sections:

15.2.1. Choosing Adiabatic or Non-Adiabatic Options
15.2.2. Specifying the Operating Pressure for the System
15.2.3. Enabling a Secondary Inlet Stream
15.2.4. Choosing to Define the Fuel Stream(s) Empirically
15.2.5. Enabling the Rich Flammability Limit (RFL) Option

15.2.1. Choosing Adiabatic or Non-Adiabatic Options

You should use the non-adiabatic modeling option if your problem definition in ANSYS Fluent will include one or more of the following:

- radiation or wall heat transfer
- multiple fuel inlets at different temperatures
- multiple oxidant inlets at different temperatures
- liquid fuel, coal particles, and/or heat transfer to inert particles

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that the adiabatic model is a simpler model involving a two-dimensional look-up table in which scalars depend only on $\overline{f}$ and $\overline{f'^2}$ (or on f_{fuel} and p_{sec}). If your model is defined as adiabatic, you will not need to solve the energy equation in ANSYS Fluent and the system temperature will be determined directly from the mixture fraction and the fuel and oxidant inlet temperatures. The non-adiabatic case will be more complex and more time-consuming to compute, requiring the generation of three-dimensional look-up tables. However, the non-adiabatic model option allows you to include the types of reacting systems described above.

Select **Adiabatic** or **Non-Adiabatic** in the **Chemistry** tab of the **Species Model** dialog box.

15.2.2. Specifying the Operating Pressure for the System

The system **Operating Pressure** is used to calculate density using the ideal gas law. For non-adiabatic simulations, the **Compressibility Effects** under **PDF Options** can be enabled to account for cases where substantial pressure changes occur in time and/or space. In such cases it is assumed that the species mass fractions do not change with pressure, and the density is calculated as

$$\overline{\rho}=\rho_{op}\frac{\overline{p}}{\overline{p}_{op}} \tag{15.1}$$

where ρ_{op} is the density at the specified **Operating Pressure** (p_{op}), and $\overline{p}$ is the local mean pressure in an ANSYS Fluent cell.

When the **Compressibility Effects** option is enabled, the flow operating pressure (set in the **Operating Conditions** dialog box) can differ from the Non-Premixed model operating pressure. To distinguish this difference, the **Operating Pressure** name tag in the **Species Model** dialog box changes to **Equilibrium Operating Pressure** when the compressibility effects option is enabled.

See Solution Strategies for Non-Premixed Modeling (p. 1081) for details about enabling compressibility effects.

15.2.3. Enabling a Secondary Inlet Stream

If you are modeling a system consisting of a single fuel and a single oxidizer stream, you do not need to enable a secondary stream in your PDF calculation. As discussed in Definition of the Mixture Fraction in the Theory Guide, a secondary stream should be enabled if your PDF reaction model will include any of the following:

- two dissimilar gaseous fuel streams
  - In these simulations, the fuel stream defines one of the fuels and the secondary stream defines the second fuel.
- mixed fuel systems of dissimilar gaseous and liquid fuel
  - In these simulations, the fuel stream defines the gaseous fuel and the secondary stream defines the liquid fuel (or vice versa).
- mixed fuel systems of dissimilar gaseous and coal fuels
  - In these simulations, you can use the fuel stream or the secondary stream to define either the coal or the gaseous fuel. See Modeling Coal Combustion Using the Non-Premixed Model (p. 1046) regarding coal combustion simulations with the non-premixed combustion model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- mixed fuel systems of coal and liquid fuel
  - In these simulations, you can use the fuel stream or the secondary stream to define either the coal or the liquid fuel. See Modeling Coal Combustion Using the Non-Premixed Model (p. 1046) regarding coal combustion simulations with the non-premixed combustion model.
- coal combustion
  - Coal combustion can be more accurately modeled by using a secondary stream to track the distinct volatile and char off-gases. The fuel stream must define the char and the secondary stream must define the volatile components of the coal. See Modeling Coal Combustion Using the Non-Premixed Model (p. 1046) regarding coal combustion simulations with the non-premixed combustion model.
- a single fuel with two dissimilar oxidizer streams
  - In these simulations, the fuel stream defines the fuel, the oxidizer stream defines one of the oxidizers, and the secondary stream defines the second oxidizer.

To include a secondary stream in your model, turn on the **Secondary Stream** option under **Stream Options** in the **Chemistry** tab.

Important

Using a secondary stream can substantially increase the calculation time for your simulation since the multi-dimensional PDF integrations are performed at run time. Alternatively, ANSYS Fluent can perform a full tabulation of the PDF integrations, as detailed in Full Tabulation of the Two-Mixture-Fraction Model (p. 1067).

15.2.4. Choosing to Define the Fuel Stream(s) Empirically

The empirical fuel option provides an alternative method for defining the composition of the fuel or secondary stream when the individual species components of the fuel are unknown. That is, you will define the elemental fraction *not* the individual species. When this option is disabled, you will define the chemical species that are present in each stream and the mass or mole fraction of each species, as described in Defining the Stream Compositions (p. 1042). The option for defining an empirical fuel stream is particularly useful for coal combustion simulations (see Modeling Coal Combustion Using the Non-Premixed Model (p. 1046)) or for simulations involving other complex hydrocarbon mixtures.

To define a fuel or secondary stream empirically

1. Turn on the **Empirical Fuel Stream** option under **Stream Options** in the **Chemistry** tab of the **Species Model** dialog box. If you have a secondary stream, enable the **Empirical Secondary Stream** option, or both as appropriate.
2. Specify the appropriate lower heating value (for example **Empirical Fuel Lower Caloric Value**, **Empirical Secondary Lower Caloric Value**), specific heat (**Empirical Fuel Specific Heat**, **Empirical Secondary**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Specific Heat), and molecular weight (**Empirical Fuel Molecular Weight**, **Empirical Secondary Molecular Weight**) for each empirically defined stream.

Important

The empirical definition option is available only with the full equilibrium chemistry model. It cannot be used with the rich flammability limit (RFL) option or the steady and unsteady diffusion flamelet models, since equilibrium calculations are required for the determination of the fuel composition.

Important

The empirical fuel and secondary molecular weights are only required if your empirical streams are entering the domain via an inlet boundary, or if you are using the partially premixed model. If you are using the non-premixed model and the empirically defined streams originate from the dispersed phase (for example, if you are modeling coal or liquid fuel combustion) the molecular weights are not required for the computation.

15.2.5. Enabling the Rich Flammability Limit (RFL) Option

You can define a rich limit on the mixture fraction when the equilibrium chemistry option is used. Input of the rich limit is accomplished by specifying a value of the **Rich Flammability Limit** for the appropriate **Fuel Stream**, **Secondary Stream**, or both. You will not be allowed to specify the **Rich Flammability Limit** if you have used the empirical definition option for fuel composition.

ANSYS Fluent will compute the composition at the rich limit using equilibrium. For mixture fraction values above this limit, ANSYS Fluent will suspend the equilibrium chemistry calculation and will compute the composition based on mixing, but not burning, of the fuel with the composition at the rich limit. A value of 1.0 for the rich limit implies that equilibrium calculations will be performed over the full range of mixture fraction. When you use a rich limit that is less than 1.0, equilibrium calculations are suspended whenever f, f_{fuel}, or f_{sec} exceeds the limit. This RFL model is often more accurate than the assumption of chemical equilibrium for rich mixtures, and also avoids complex equilibrium calculations, speeding up the preparation of the look-up tables. An RFL value of approximately twice the stoichiometric mixture fraction is appropriate.

For the **Secondary Stream**, the rich flammability limit controls the equilibrium calculation for the secondary mixture fraction. If your secondary stream is not a fuel, you should use an RFL value of 1. A value of 1.0 for the rich limit implies that equilibrium calculations will be performed over the full range of mixture fraction. When you input a rich limit that is less than 1.0, equilibrium calculations are suspended whenever f_{sec} exceeds the limit. (Note that it is the secondary mixture fraction f_{sec} and not the partial fraction p_{sec} that is used here.)

Important

Experimental studies and reviews [12] (p. 2887), [106] (p. 2892) have shown that although the fuel-lean flame region approximates thermodynamic equilibrium, non-equilibrium kinetics will prevail under fuel-rich conditions. Therefore, for non-empirically defined fuels, the RFL model is strongly recommended.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

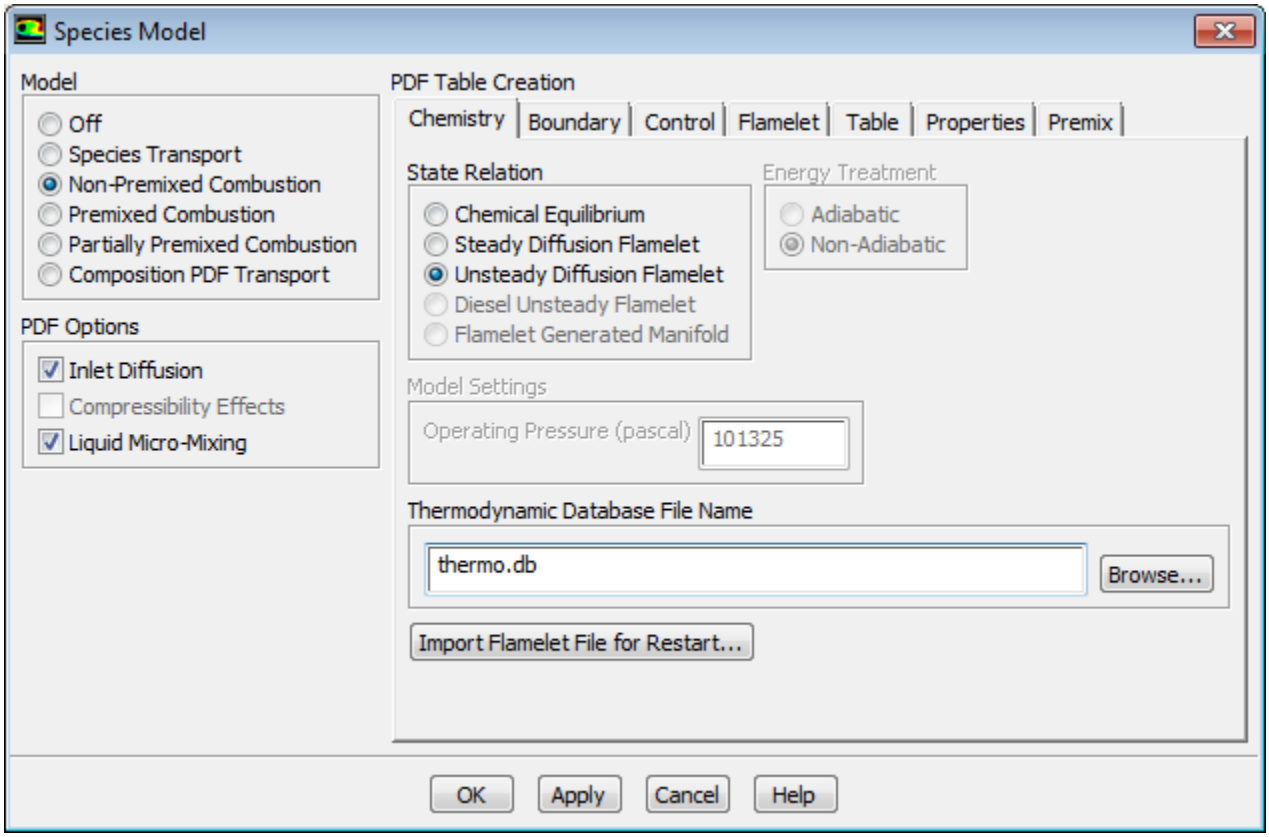
15.3. Setting Up the Steady and Unsteady Diffusion Flamelet Models

To enable the diffusion flamelet models

1. Select **Non-Premixed Combustion** in the **Species Model** dialog box.

2. Select **Steady Diffusion Flamelet** or **Unsteady Diffusion Flamelet** in the **Chemistry** tab of the **Species Model** dialog box. See Using the Unsteady Diffusion Flamelet Model (p. 1037).

Figure 15.7: The Chemistry Tab for the Unsteady Diffusion Flamelet Model



For additional information, see the following sections:

15.3.1. Choosing Adiabatic or Non-Adiabatic Options
15.3.2. Specifying the Operating Pressure for the System
15.3.3. Specifying a Chemical Mechanism File for Flamelet Generation
15.3.4. Importing a Flamelet
15.3.5. Using the Unsteady Diffusion Flamelet Model
15.3.6. Using the Diesel Unsteady Laminar Flamelet Model
15.3.7. Resetting Diesel Unsteady Flamelets

15.3.1. Choosing Adiabatic or Non-Adiabatic Options

Select **Adiabatic** or **Non-Adiabatic** in the **Chemistry** tab of the **Species Model** dialog box. See the discussion in Choosing Adiabatic or Non-Adiabatic Options (p. 1032) about the two options.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.3.2. Specifying the Operating Pressure for the System

The system **Operating Pressure** is used to calculate density using the ideal gas law. When the **Compressibility Effects** option is enabled, the name **Operating Pressure** is changed to **Equilibrium Operating Pressure** since the non-premixed combustion model operating pressure can differ from the flow operating pressure. Specifying the Operating Pressure for the System (p. 1033) provides more information about this value.

You can use the steady or unsteady diffusion flamelet model for reactions in liquid systems. To do so, enable **Liquid Micro-Mixing** under **PDF Options**. The **Liquid Micro-Mixing** option is discussed in detail in Liquid Reactions in the Theory Guide.

15.3.3. Specifying a Chemical Mechanism File for Flamelet Generation

If you are generating a flamelet file yourself, you will need to read in the chemical kinetic mechanism and thermodynamic data. The mechanism and thermodynamic data must be in CHEMKIN format [52] (p. 2889).

To read in a CHEMKIN mechanism, select the **Create Flamelet** option in the **Chemistry** tab of the **Species Model** dialog box and click the **Import CHEMKIN Mechanism...** button. Using the **CHEMKIN Mechanism Import** dialog box, import the gas-phase CHEMKIN files into ANSYS Fluent as described in Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967). Note that for flamelet generation, only a gas-phase kinetic mechanism and a thermodynamic database are required.

Note that the import is limited to mechanisms with 700 or fewer species.

15.3.4. Importing a Flamelet

To import an existing flamelet file

1. Select the **Import Flamelet** option in the **Chemistry** tab of the **Species Model** dialog box.
2. (steady diffusion flamelet only) Select either **Standard** or **CFX-RIF** format under **File Type**.
3. Click the **Import Flamelet File...** button. In The Select File Dialog Box (p. 19), select the file (for a single flamelet) or files (for multiple flamelets) to be read in to ANSYS Fluent.

After you have completed this step, you can skip ahead to the **Table** tab of the **Species Model** dialog box (see Calculating the Look-Up Tables (p. 1063)).

15.3.5. Using the Unsteady Diffusion Flamelet Model

The unsteady diffusion flamelet model can only be enabled from a valid steady-state, steady diffusion flamelet solution. When enabled, the unsteady diffusion flamelet model will change this case to unsteady and postprocess marker probability equations on the frozen flow field. You should hence ensure that the starting steady-state, steady diffusion flamelet solution is fully converged.

When the **Unsteady Diffusion Flamelet** is enabled in the **Chemistry** tab, the **Import Flamelet File for Restart...** button appears in the dialog box, allowing you to run the simulation from a previously saved case, data and unsteady flamelet file.

The Unsteady Diffusion Flamelet Model requires four user inputs in the **Flamelet** tab:

- The **Number of Grid Points in Flamelet**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Mixture Fraction Lower Limit for Initial Probability**. The initial condition of the marker probability field is unity for all mean mixture fractions above the **Mixture Fraction Lower Limit for Initial Probability**, and zero for mean mixture fractions below it. Note that this should be specified to be greater than the stoichiometric mixture fraction.

- **Maximum Scalar Dissipation**. Flamelets may extinguish at high scalar dissipations because diffusion in the flamelet overwhelms reaction. It is possible to have unrealistically high modeled scalar dissipation in the 2D or 3D ANSYS Fluent simulations, which gets transferred to the 1D unsteady flamelet. In order to avoid excessive diffusion in the 1D unsteady flamelet, the instantaneous scalar dissipation in the 1D flamelet is limited to the specified **Maximum Scalar Dissipation**.

- **Courant Number**. The time step for the unsteady probability marker equation is calculated automatically by ANSYS Fluent based on the **Courant Number**. Larger values imply fewer time steps to convect/diffuse the marker probability out of the domain, but also results in a larger numerical error. The **Courant Number** should be small enough so that the unsteady flamelet mean mass fractions are unchanged with any smaller **Courant Number**. The default value of 1 should be sufficient for most applications.

- **Number of Flamelets**. The number of unsteady laminar flamelets that ANSYS Fluent will generate during the run. The marker probability equation Equation 8.56 in the *Fluent Theory Guide* will be solved for each flamelet.

When these inputs have been set, clicking the **Initialize Unsteady Flamelet Probability** button initializes the marker probability equation for each flamelet, automatically enabling the **Unsteady** solver, while disabling all equations except the **Unsteady Flamelet Probability** equation in the **Solution Controls** task page. This initialization in the **Flamelet** tab also sets the **Time Step Size** in the **Run Calculation** task page.

Important

- Do not initialize your solution from the tree or the **Solution Initialization** task page. Note that you are postprocessing a probability field on the frozen steady-state flow field, and by clicking the **Initialize Unsteady Flamelet Probability** button, you have already initialized the probability marker field.

- If you disable the **Unsteady Diffusion Flamelet** model and you want to revert to solving a steady diffusion flamelet simulation, make sure you enable **Steady** (either in the **General** task page or in the tree from the **Setup**/**General**/ **Analysis Type** tree item) and enable all the equations (in the **Solution Controls** task page or in the tree from the **Solution**/**Solution Controls** tree item).

15.3.6. Using the Diesel Unsteady Laminar Flamelet Model

The diesel unsteady laminar flamelet model can only be enabled when conditions for compression-ignition are met:

- The **Transient** solver is selected in the **General** task page (or in the tree from the **Setup**/**General**/ **Analysis Type**).

- The **In-Cylinder** dynamic mesh is enabled.

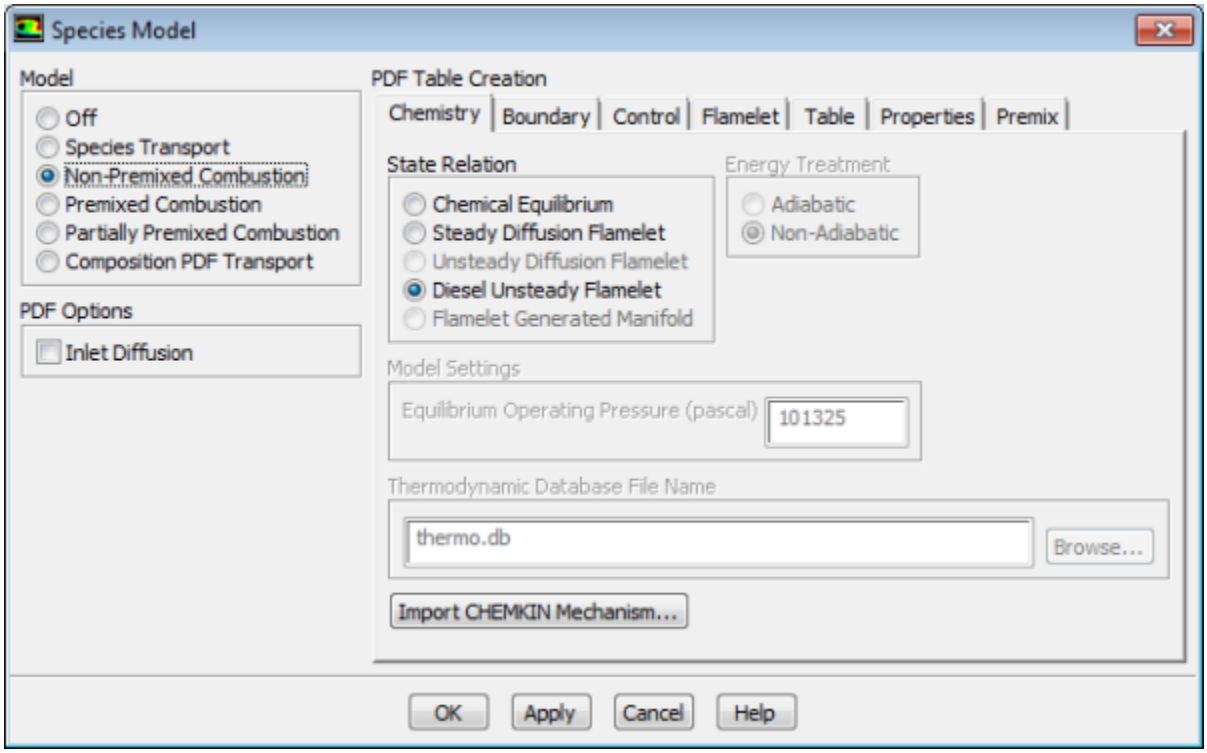
- The Discrete Phase model option **Interaction with Continuous Phase** is selected.

The basic steps for setting the diesel unsteady laminar flamelet models are as follows.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. In the **Chemistry** tab, select **Diesel Unsteady Flamelet**.

Figure 15.8: The Enabled Diesel Unsteady Flamelet Model



2. If a detailed chemical mechanism containing kinetic reactions appropriate for compression ignition has not yet been defined in your case, you can import a mechanism in CHEMKIN format as described in Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967).

   The mechanism can include pollutant formation reactions as well if you are interested in modeling emissions.

3. In the **Boundary** tab, define the stream compositions as described in Defining the Stream Compositions (p. 1042).

4. In the **Flamelet** tab, set the following flamelet parameters.

   a. Set the **Number of Grid Points in Flamelet**.

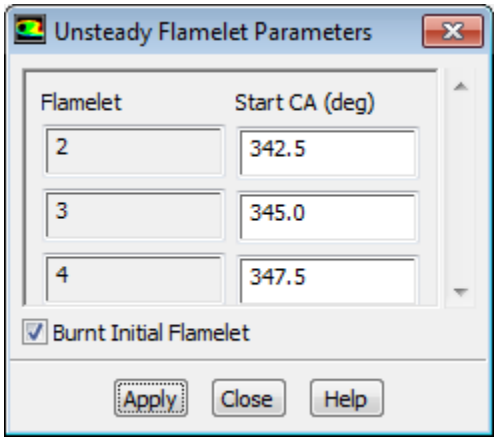
   b. Set the **Number of Unsteady Flamelets** that ANSYS Fluent will generate during simulation.

   c. (for multiple unsteady flamelets) Set the flamelet start times.

      ANSYS Fluent automatically sets the start time for the first flamelet, but you must set the start time for each consecutive flamelet using the **Unsteady Flamelet Parameters** dialog box. Open it by clicking **Set Flamelet Parameters** and enter the start time for each flamelet either in seconds or in crank angles if the dynamic mesh is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.9: The Unsteady Flamelet Parameters Dialog Box



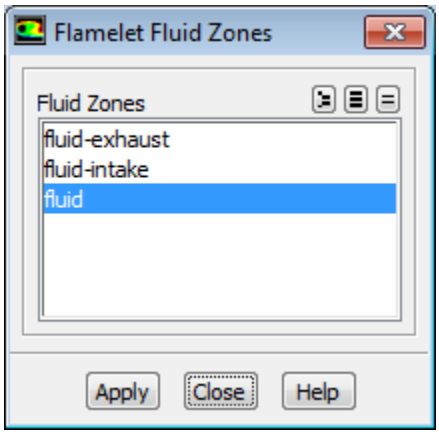
ANSYS Fluent starts simulation with only one flamelet, and then it automatically introduces new flamelets into the reacting domain at the times you have specified.

d. The default initial condition for an unsteady flamelet is unburnt. ANSYS Fluent provides the **Burnt Initial Flamelet** option that allows you to set the initial flamelet condition to a chemical equilibrium burnt state. This option is useful if you are modeling internal combustion engines where residual gases may be present in the cylinder before the spray is injected, which would be incorrectly modeled by the unburnt state. Note that the **Burnt Initial Flamelet** is only used at case initialization.

e. (optional) Specify the flamelet fluid zones.

ANSYS Fluent calculates diesel unsteady flamelets using the zone-averaged pressure and scalar dissipation at every time step. By default, the averaging is performed over all fluid zones in the domain, but you can also select and/or deselect the fluid zones using the **Flamelet Fluid Zones** dialog box. Open this dialog box by clicking **Set Flamelet Fluid Zones** and select the fluid zones to be used for calculating average pressure and scalar dissipation. If no fluid zone is selected, ANSYS Fluent will compute domain average pressure and scalar dissipation using all fluid zones.

Figure 15.10: The Flamelet Fluid Zones Dialog Box



Note

For internal combustion cases, it is recommended that you select the cylinder fluid zones and deselect the intake and exhaust fluid zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that ANSYS Fluent calculates flamelets at every time step of the run. For this reason, the option to calculate the flamelets as a preprocessing step before running your simulation is unavailable, and **Calculate Flamelets** appears dimmed.

5. In the **Table** tab, set the PDF table parameters as described in Calculating the Look-Up Tables (p. 1063).

   Note that ANSYS Fluent calculates PDF table at every time step of the run. For this reason, the option to calculate the PDF table as a preprocessing step before running your simulation is unavailable, and **Calculate PDF Table** appears dimmed.

15.3.6.1. Recommended Settings for Internal Combustion Engines

When setting up and using the Diesel Unsteady Flamelet model for internal combustion engine simulations, the following recommendations apply:

1. Number of Flamelets

   a. You must specify at least two diesel unsteady flamelets. ANSYS Fluent will use the first flamelet to model trapped burnt gases from the previous cycle. The second flamelet will start at the crank angle (CA) of fuel injection, specified in the **Unsteady Flamelet Parameters** dialog box (see Figure 15.10: The Flamelet Fluid Zones Dialog Box (p. 1040)).

   b. To model split injections where an initial fuel mass is injected and burns before the main fuel injection, three or more unsteady flamelets are required.

2. Flamelet Initialization

   By default, the flamelet is initialized as mixed-but-unburnt. However, in all practical scenarios there is always some trapped gas remaining inside the cylinder. Therefore, it is recommended that you use the **Burnt Initial Flamelet** option in the **Unsteady Flamelet Parameters** dialog box (see Figure 15.10: The Flamelet Fluid Zones Dialog Box (p. 1040)). When this option is selected, ANSYS Fluent performs a constant temperature equilibrium calculation and sets the initial flamelet condition to a chemical equilibrium burnt state.

3. Multi-cycle simulations

   a. To accurately model multiple cycles of internal combustion engines, the flamelets must be reset at the end of each cycle. This is performed by defining the **Diesel Unsteady Flamelet Reset** event, typically at the specified crank angle, just before the inlet valve opens. Refer to the Resetting Diesel Unsteady Flamelets (p. 1041) for details. This approach is recommended for modeling the EGR trapped gases with the first burnt unsteady flamelet.

   b. If you are using the Inert (EGR) model in order to track the trapped inert mixture, you need to define the **Inert EGR Reset** event at the specified crank angle just before the inlet valve opens. See Resetting Inert EGR (p. 1077) for details.

15.3.7. Resetting Diesel Unsteady Flamelets

In order to simulate multiple cycles in internal combustion engines, flamelets should be reset at the end of every cycle. In addition, the burned trapped gases must be modeled, which can be done in one of the two ways. The first and recommended approach is to use the **Diesel Unsteady Flamelet Reset** option. The second approach is to use the inert (EGR) model and the **Inert EGR Reset** option. You can access the **Diesel Unsteady Flamelet Reset** and **Inert EGR Reset** options via the **Dynamic Mesh Events** dialog box. There, you need to set the crank angle at which this event occurs (usually shortly before

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the inlet valves open) and the participating fluid zones (usually only the combustion chamber and not the intake and exhaust port zones).

When the **Diesel Unsteady Flamelet Reset** event is executed, all flamelets are deleted and a new flamelet is introduced with a state set to the probability-weighted average condition of all flamelets present before reset. The other new flamelets are introduced during a new cycle in a similar fashion to that described in Using the Diesel Unsteady Laminar Flamelet Model (p. 1038).

When the inert EGR reset event is executed with the diesel unsteady flamelet model, the burnt gas in the selected Inert EGR Reset zones is converted to inert, all flamelets are deleted, and a new unburnt flamelet is introduced into the domain.

Note

The **Diesel Unsteady Flamelet Reset** option is available only when the selected number of flamelets is greater than one.

15.4. Defining the Stream Compositions

In modeling a non-premixed combustion problem, you will only specify the boundary species (that is, the fuel, oxidizer, and if necessary, secondary stream species). The intermediate and product species will be determined automatically.

ANSYS Fluent provides you with an initial list of common boundary species (ch4, h2, jet-a<g>, n2 and o2). If your fuel and/or oxidizer is composed of different species, you can add them to the boundary **Species** list. All boundary species must exist in the chemical database and you must enter their names in the same format used in the database, otherwise an error message will be issued.

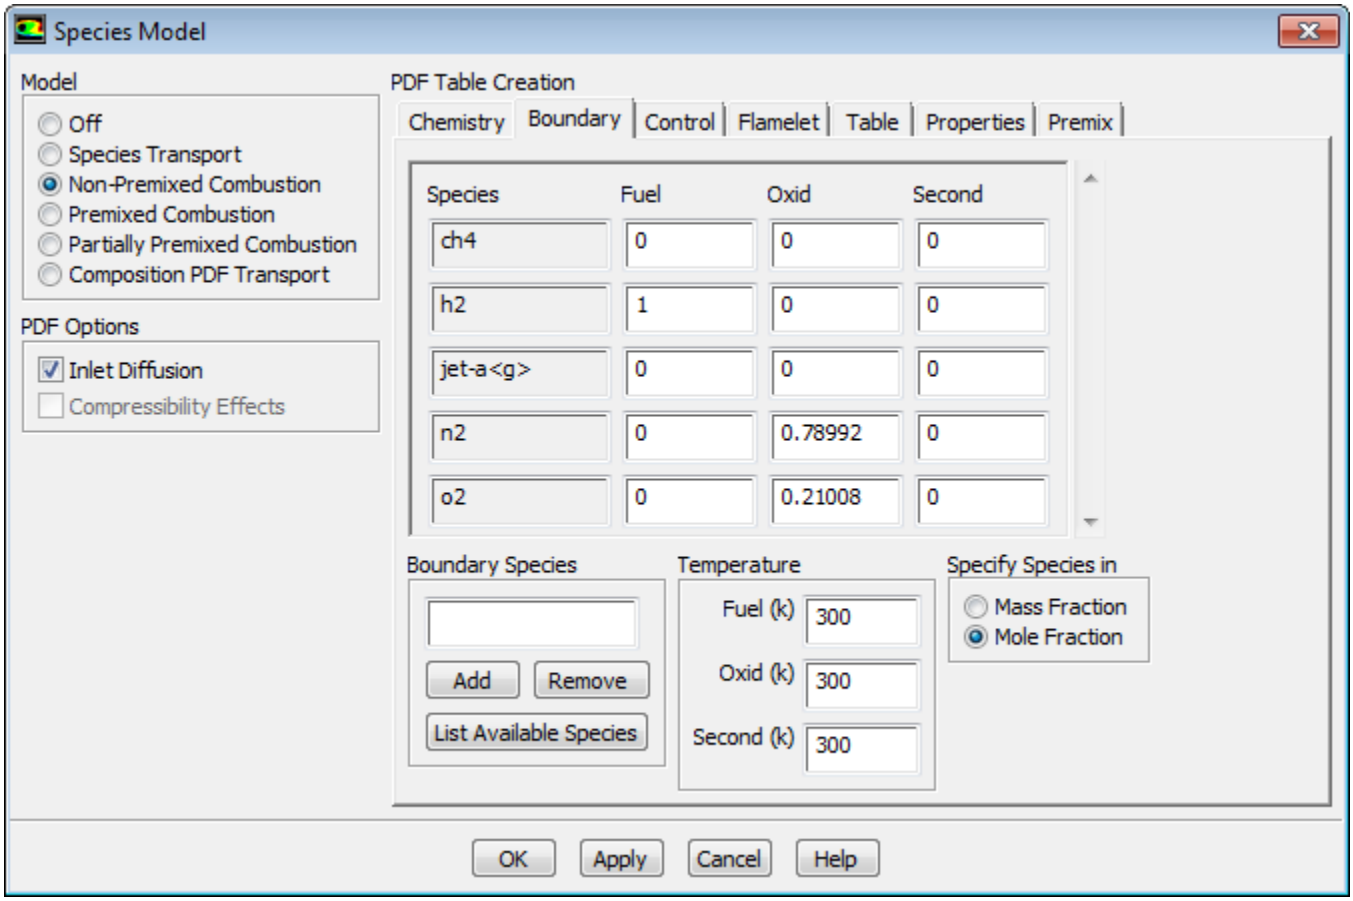
After defining the boundary species that will be considered in the reaction system, you must define their mole or mass fractions at the fuel and oxidizer inlets and at the secondary inlet, if one exists. (If you choose to define the fuel or secondary stream composition empirically, you will instead enter the parameters described at the end of this section.) For the example shown in Figure 8.12: Chemical Systems That Can Be Modeled Using a Single Mixture Fraction in the Theory Guide, for example, the fuel inlet consists of 60% CH_4, 20% CO, 10% CO_2, and 10% C_3H_8.

Finally, the inlet stream temperatures of your reacting system are required for construction of the look-up table and computation of the equilibrium chemistry model.

For the equilibrium chemistry model, the species names are entered using the **Boundary** tab in the **Species Model** dialog box (Figure 15.11: The Species Model Dialog Box (Boundary Tab) (p. 1043)). If you are generating a steady or unsteady diffusion flamelet, the list of boundary species will be automatically filled as all the species in the CHEMKIN mechanism, and you will be unable to change these.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.11: The Species Model Dialog Box (Boundary Tab)



The steps for adding new species and defining their compositions are as follows:

1. (chemistry equilibrium chemistry model only) If your fuel, oxidizer, or secondary streams are composed of species other than the default species list, type the chemical formula (for example, `so2` or `S02` for SO_2) under **Boundary Species** and click **Add**. The species will be added to the **Species** list. Continue in this manner until all of the boundary species you want to include are shown in the **Species** list.

   To remove a species from the list, type the chemical formula under **Boundary Species** and click **Remove**. To print a list of all species in the thermodynamic database file (`thermo.db`) in the console window, click **List Available Species**.

2. (non-equilibrium chemistry models) Optionally, select the boundary species as described in Overview of the Problem Setup Procedure (p. 1026).

3. Under **Specify Species In**, specify whether you want to enter the **Mass Fraction** or **Mole Fraction**. **Mass Fraction** is the default.

4. For each relevant species in the **Species** list, specify its mass or mole fraction for each stream (**Fuel**, **Oxid**, or **Second** as appropriate) by entering values in the table. Note that if you change from **Mass Fraction** to **Mole Fraction** (or vice versa), all values will be automatically converted if they sum to 0 or 1, so be sure that you are entering either all mass fractions or all mole fractions as appropriate. If the values do not sum to 0 or 1, an error will be issued.

5. Under **Temperature**, specify the following inputs:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fuel

is the temperature of the fuel inlet in your model. In adiabatic simulations, this input (together with the oxidizer inlet temperature) determines the inlet stream temperatures that will be used by ANSYS Fluent. In non-adiabatic systems, this input should match the inlet thermal boundary condition that you will use in ANSYS Fluent (although you will enter this boundary condition again in the ANSYS Fluent session). If your ANSYS Fluent model will use liquid fuel or coal combustion, define the inlet fuel temperature as the temperature at which vaporization/devolatilization begins (that is, the **Vaporization Temperature** specified for the discrete-phase material—see Setting Material Properties for the Discrete Phase (p. 1313)). For such non-adiabatic systems, the inlet temperature will be used only to adjust the look-up table grid (for example, the discrete enthalpy values for which the look-up table is computed). Note that if you have more than one fuel inlet, and these inlets are not at the same temperature, you must define your system as non-adiabatic. In this case, you should enter the fuel inlet temperature as the value at the dominant fuel inlet.

Oxid

is the temperature of the oxidizer inlet in your model. The issues raised in the discussion of the input of the fuel inlet temperature (directly above) pertain to this input as well.

Second

is the temperature of the secondary stream inlet in your model. (This item will appear only when you have defined a secondary inlet.) The issues raised in the discussion of the input of the fuel inlet temperature (directly above) pertain to this input as well.

For additional information, see the following sections:

15.4.1. Setting Boundary Stream Species
15.4.2. Modifying the Database
15.4.3. Composition Inputs for Empirically-Defined Fuel Streams
15.4.4. Modeling Liquid Fuel Combustion Using the Non-Premixed Model
15.4.5. Modeling Coal Combustion Using the Non-Premixed Model

15.4.1. Setting Boundary Stream Species

In combustion, a large number of intermediate and product species may be produced from a small number of initial boundary species. In ANSYS Fluent you must specify only the species composition of your boundary species in the fuel, oxidizer, and (if appropriate) secondary streams. ANSYS Fluent will calculate all intermediate and product species automatically. The following suggestions may be helpful in the definition of the system chemistry:

- For coal combustion, char in the coal should be represented by C(s).

  Important

  Care should be taken to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should be selected only if you are using the empirically-defined input method.

- If your fuel composition is known empirically (for example, $C_{0.9}H_3O_{0.2}$), use the option for an empirically-defined stream (see below).

- If you want to include the sulfur that may be present in a hydrocarbon fuel, note that this may hinder the convergence of the equilibrium solver, especially if the concentration of sulfur is small. It is therefore recommended that you include sulfur in the calculation only if it is present in considerable quantities.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.4.1.1. Including Condensed Species

In addition to gaseous species, liquid and solid species can be included in the chemistry calculations. They are often indicated by an "l" or an "s" in parentheses after the species name. If you add a condensed species to the equilibrium chemical system, its density will be retrieved from ANSYS Fluent's chemical property database file `propdb.scm` if you are using the thermodynamic database file `thermo.db` that is also supplied with ANSYS Fluent. If you are using a custom thermodynamic database file and want to include a condensed species in the equilibrium system that does not exist in `propdb.scm`, a density of 1000 kg/m^3 will be assumed. The condensed species density can be changed in the Create/Edit Materials Dialog Box (p. 2302) after the PDF table has been calculated. If you modify the condensed species density in this manner, you will then need to recalculate the PDF table.

15.4.2. Modifying the Database

If you want to include a new species in your reacting system that is not available in the chemical database, you can add it to the database file, `thermo.db`. The format for `thermo.db` is detailed in [52] (p. 2889). If you choose to modify the standard database file, you should create copies of the original file.

15.4.3. Composition Inputs for Empirically-Defined Fuel Streams

As mentioned in Defining the Problem Type (p. 1026), you can define the composition of a fuel stream (that is, the standard fuel or a secondary fuel) empirically. For an empirically-defined stream, you will need to enter the atomic mass or mole fractions in addition to the inputs for lower caloric (heating) value of the fuel and the mean specific heat of the fuel that were described previously.

The heat of formation of an empirically defined stream is calculated from the heating value and the atomic composition. The fuel inlet temperature and fuel specific heat are used to calculate the sensible enthalpy. The molecular weight is used for the computation of the unburnt stream density. Note that the unburnt density is only required if the stream enters via an inlet boundary, or if you are using the partially-premixed model.

When an empirically-defined fuel or secondary stream is specified in the **Chemistry** tab (equilibrium chemistry model only) of the **Species Model** dialog box, you must specify the atom fractions of C, H, O, N, and S in that stream instead of the species mass or mole fractions. To avoid confusion, the species fraction inputs for an empirically-defined stream will be grayed out in the table within the **Boundary** tab, leaving only the fields for atom fractions (that is, **c**, **h**, **o**, **n**, and **s**).

15.4.4. Modeling Liquid Fuel Combustion Using the Non-Premixed Model

Liquid fuel combustion can be modeled with the discrete phase and non-premixed models. In ANSYS Fluent, the fuel vapor, which is produced by evaporation of the liquid fuel, is defined as the fuel stream. (See Defining the Stream Compositions (p. 1042).) The liquid fuel that evaporates within the domain appears as a source of the mean fuel mixture fraction.

Within ANSYS Fluent, you define the liquid fuel discrete-phase model in the usual way. The gas phase (oxidizer) flow inlet is modeled using an inlet mixture fraction of zero and the fuel droplets are introduced as discrete phase injections (see Setting Initial Conditions for the Discrete Phase (p. 1265)). The property inputs for the liquid fuel droplets are unaltered by the non-premixed model (see Setting Material Properties for the Discrete Phase (p. 1313)). Note that when you are requested to input the gas phase species destination for the evaporating liquid, you should specify the species that comprises the evaporating stream.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If the fuel stream was defined as a mixture of components, you should select the largest of these components as the "evaporating species". ANSYS Fluent will ensure that the mass evaporated from the liquid droplet enters the gas phase as a source of the fuel mixture that you defined. The evaporating species you select here is used only to compute the diffusion controlled driving force in the evaporation rate.

15.4.5. Modeling Coal Combustion Using the Non-Premixed Model

If your model involves coal combustion, the fuel and secondary stream compositions can be input in one of several ways. You can use a single mixture fraction (fuel stream) to represent the coal, defining the fuel composition as a mixture of volatiles and char (solid carbon). Alternatively, you can use two mixture fractions (fuel and secondary streams), defining the volatiles and char separately. In two-mixture-fraction models for coal combustion, the fuel stream represents the char and the secondary stream represents volatiles. This section describes the modeling options and special input procedures for coal combustion models using the non-premixed approach.

There are three options for coal combustion:

- When coal is the only fuel in the system, you can model the coal using two mixture fractions, where the primary stream represents the char and the secondary stream represents the volatiles. Generally, the char stream composition is defined as 100% C(s). The volatile stream composition is defined by selecting appropriate species and setting their mole or mass fractions. Alternatively, you can use the empirical method (input of atom fractions) for defining these compositions.

  Important

  Using two mixture fractions to model coal combustion is more accurate than using one mixture fraction as the volatile and char streams are modeled separately. However, the two-mixture-fraction model incurs significant additional computational expense since the multi-dimensional PDF integrations are performed at run time.

- When coal is the only fuel in the system, you can choose to model the coal using a single mixture fraction (the fuel stream). When this approach is adopted, the fuel composition you define includes both volatile species and char. Char is typically represented by including C(s) in the species list. You can define the fuel stream composition by selecting appropriate species and setting their mole fractions, or by using the empirical method (input of atom fractions). Definition of the composition is described in detail below.

  Important

  Using a single mixture fraction for coal combustion is less accurate than using two mixture fractions. However, convergence in ANSYS Fluent should be substantially faster than the two-mixture-fraction model.

- When coal is used with another (gaseous or liquid) fuel of different composition, you must model the coal with one mixture fraction and use a second mixture fraction to represent the second (gaseous or liquid) fuel. The stream associated with the coal composition is defined as detailed below for single-mixture-fraction models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.4.5.1. Defining the Coal Composition: Single-Mixture-Fraction Models

When coal is modeled using a single mixture fraction (the fuel stream), the fuel stream composition can be input using the conventional approach or the empirical fuel approach.

- Conventional approach:

  To use the conventional approach, you will need to define the mixture of species in the coal and their mole or mass fractions in the fuel stream. Use the **Boundary** tab in the **Species Model** dialog box to input the list of species (for example, C_3H_8, CH_4, CO, CO_2, C(s)) that approximate the coal composition, and their mole or mass fractions.

  Note that C(s) is used to represent the char content of the coal. For example, consider a coal that has a molar composition of 40% volatiles and 60% char on a dry ash free (DAF) basis. Assuming the volatiles can be represented by an equimolar mixture of C_3H_8 and CO, the fuel stream composition defined in the **Boundary** tab would be C_3H_8=0.2, CO = 0.2, and C(s)=0.60. Note that the coal composition should always be defined on an ash-free basis, even if ash will be considered in the ANSYS Fluent calculation.

  To define ash properties, go to the **Create/Edit Materials** dialog box and select **combusting-particle** as the **Material Type**.

  The following table illustrates the conversion from a typical mass-based proximate analysis to the species fraction inputs required by ANSYS Fluent. Note that the conversion requires that you make an assumption regarding the species representing the volatiles. Here, the volatiles are assumed to exist as an equimolar mix of propane and carbon monoxide.

Proximate Analysis	Weight %	Mass Fraction (DAF)	Moles (DAF)	Mole Fraction (DAF)
Volatiles	30			
– C_3H_8		0.2035	0.004625	0.07134
– CO		0.1295	0.004625	0.07134
Fixed Carbon (C(s))	60	0.667	0.05558	0.85732
Ash	10	-	-	-
(Total)			0.06483	1.0

  Moisture in the coal can be considered by adding it in the fuel composition as liquid water, H_2O(l). The moisture can also be defined as water vapor, H_2O, provided that the corresponding latent heat is included in the discrete phase material inputs in ANSYS Fluent. If the liquid water is used as a boundary species, it should be removed from the list of excluded species (see Forcing the Exclusion and Inclusion of Equilibrium Species (p. 1053)).

  Important

  Note that if water is included in the coal, the water release is not modeled as evaporation, which is typically the case in the wet combustion model, described in Particle Types (p. 1268).

- Empirical fuel approach:

To use the empirical approach, enable the **Empirical Fuel Stream** option in the **Chemistry** tab. This method is ideal if you have an elemental analysis of the coal.

In the **Chemistry** tab, enter the lower heating value and mean specific heat of the coal. ANSYS Fluent will use these inputs to determine the mole fractions of the chemical species you have included in the system. Then, in the **Boundary** tab, define the atom fractions of C, H, N, S, and O in the fuel stream.

Note that for both of these composition input methods, you should take care to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should only be selected if you are using the empirical fuel input method.

See Additional Coal Modeling Inputs in ANSYS Fluent (p. 1049) for details about further inputs for modeling coal combustion.

15.4.5.2. Defining the Coal Composition: Two-Mixture-Fraction Models

You can model coal using the two mixture fractions model, where the primary stream represents the char and the secondary stream represents the volatiles.

As in single-mixture-fraction cases, the fuel stream and secondary stream compositions in a two-mixture-fraction case can be entered using either the conventional approach or the empirical fuel approach.

- Conventional approach:

  To use the conventional approach, you will need to define the mixture of species in the coal and their mole or mass fractions in the fuel and secondary streams.

  Use the **Boundary** tab of **Species Model** dialog box to define the mole or mass fractions of volatile species in the secondary stream (for example, C_3H_8, CH_4, CO, CO_2, C(s)). Next, define the mole or mass fractions of species used to represent the char. Generally, you will specify 100% C(s) for the fuel stream.

- Empirical fuel approach:

  To use the empirical fuel approach, enable the **Empirical Secondary Stream** option in the **Chemistry** tab for the volatile (secondary) stream. This method is ideal if you have an elemental analysis of the coal.

  In the **Chemistry** tab, input the lower heating value and mean specific heat of the coal volatiles. Then, in the **Boundary** tab, define the mole or mass fractions of species used to represent the char. Generally, you will specify 100% C(s) for the fuel stream. Finally, define the atom fractions of C, H, N, S, and O in the volatiles. ANSYS Fluent will use these inputs to determine the mole fractions of the chemical species you have included in the system. For example, consider coal with the following DAF (dry ash free) data and elemental analysis:

Proximate Analysis	Wt % (dry)	Wt % (DAF)
Volatiles	28	30.4
Char (C(s))	64	69.6
Ash	8	-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Element	Wt % (DAF)	Wt % (DAF)
C	89.3	89.3
H	5.0	5.0
O	3.4	3.4
N	1.5	2.3
S	0.8	-

(Note that in the final column, for modeling simplicity, the sulfur content of the coal has been combined into the nitrogen mass fraction.)

You can combine the proximate and ultimate analysis data to yield the following elemental composition of the volatile stream:

Element	Mass	Mass Fraction	Moles	Mole Fraction
C	(89.3 - 69.6)	0.65	5.4	0.24
H	5.0	0.16	16	0.70
O	3.4	0.11	0.7	0.03
N	2.3	0.08	0.6	0.03
Total	30.4		22.7	

This adjusted composition is used to define the secondary stream (volatile) composition.

The lower heating value of the volatiles can be computed from the known heating value of the coal and the char (DAF):

$LCV_{coal,DAF}=35.3\,\mathrm{MJ/kg}$

$LCV_{char,DAF}=32.9\,\mathrm{MJ/kg}$

You can compute the heating value of the volatiles as

$$LCV_{vol}=\frac{35.3\,\mathrm{MJ/kg}-0.696\times 32.9\,\mathrm{MJ/kg}}{0.304} \tag{15.2}$$

or

$$LCV_{vol}=40.795\,\mathrm{MJ/kg} \tag{15.3}$$

Note that for both of these composition input methods, you should take care to distinguish atomic carbon, C, from solid carbon, C(s). Atomic carbon should only be selected if you are using the empirical fuel input method.

15.4.5.3. Additional Coal Modeling Inputs in ANSYS Fluent

Within ANSYS Fluent, the DPM coal combustion simulation is defined as usual when the non-premixed combustion model is selected. The air (oxidizer) inlets are defined as having a mixture fraction value of zero. No gas phase fuel inlets will be included and the sole source of fuel will come from the coal devolatilization and char burnout. The coal particles are defined as injections using the **Set Injection Properties** dialog box in the usual way, and physical properties for the coal material are specified as described in Setting Material Properties for the Discrete Phase (p. 1313). Remember the following issues when you are defining injections and discrete-phase material properties for coal materials:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- In the **Set Injection Properties** dialog box, you will specify for the **Oxidizing Species** one of the components of the oxidizer stream. This species concentration field will be used to calculate the diffusion-controlled driving force in the char burnout law (if applicable), and is O_2 by default.

  The specification of the char and volatile streams differs depending on the type of model you are defining:

  – If coal is modeled using a single mixture fraction, the gas phase species representing the volatiles and the char combustion are represented by the mixture fraction used by the non-premixed combustion model.

  – If coal is modeled using two mixture fractions, rather than specifying a destination species for the volatiles and char, you will instead specify the **Devolatilizing Stream** (as secondary) and the **Char Stream** (as primary).

  – If coal is modeled using one mixture fraction, and another fuel is modeled using a second mixture fraction, you should specify the stream representing the coal as both the **Devolatilizing Stream** and the **Char Stream**.

- In the **Create/Edit Materials** dialog box, **Vaporization Temperature** should be set equal to the fuel inlet temperature. This temperature controls the onset of the devolatilization process. The fuel inlet temperature that you define in the **Boundary** tab of the **Species Model** dialog box should be set to the temperature at which you want to initiate devolatilization. This way, the look-up tables will include the appropriate temperature range for your process.

- In the **Create/Edit Materials** dialog box, **Volatile Component Fraction** and **Combustible Fraction** should be set to values that are consistent with the coal composition used to define the fuel (and secondary) stream composition.

- Also in the **Create/Edit Materials** dialog box, you will be prompted for the **Burnout Stoichiometric Ratio** and for the **Latent Heat**. The **Burnout Stoichiometric Ratio** is used in the calculation of the diffusion controlled burnout rate but has no other impact on the system chemistry when the non-premixed combustion model is used. The **Burnout Stoichiometric Ratio** is the mass of oxidant required per mass of char. The default value of 2.67 assumes that C(s) is oxidized by O_2 to yield CO_2. The **Latent Heat** input determines the heat required to generate the vapor phase volatiles defined in the non-premixed system chemistry. You can usually set this value to zero when the non-premixed model is used, since your definition of volatile species will have been based on the overall heating value of the coal. However, if the coal composition includes the water content, the latent heat should be set as follows:

  – Set the latent heat to zero if the water content of the coal has been defined as **H2O(L)**. In this case, the system chemistry will include the latent heat required to vaporize the liquid water.

  – Set the latent heat to the value for water (2.25×10^6 J/kg), adjusted by the mass loading of water in the volatiles, if the water content of the coal has been defined using water vapor, **H2O**. In this case, the water content you defined will be evolved along with the other species in the coal but the system chemistry does not include the latent heat effect.

- The **Density** you define for the coal in the **Create/Edit Materials** dialog box should be the apparent density, including ash content.

- You will not be asked to define the **Heat of Reaction for Burnout** for the char combustion.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

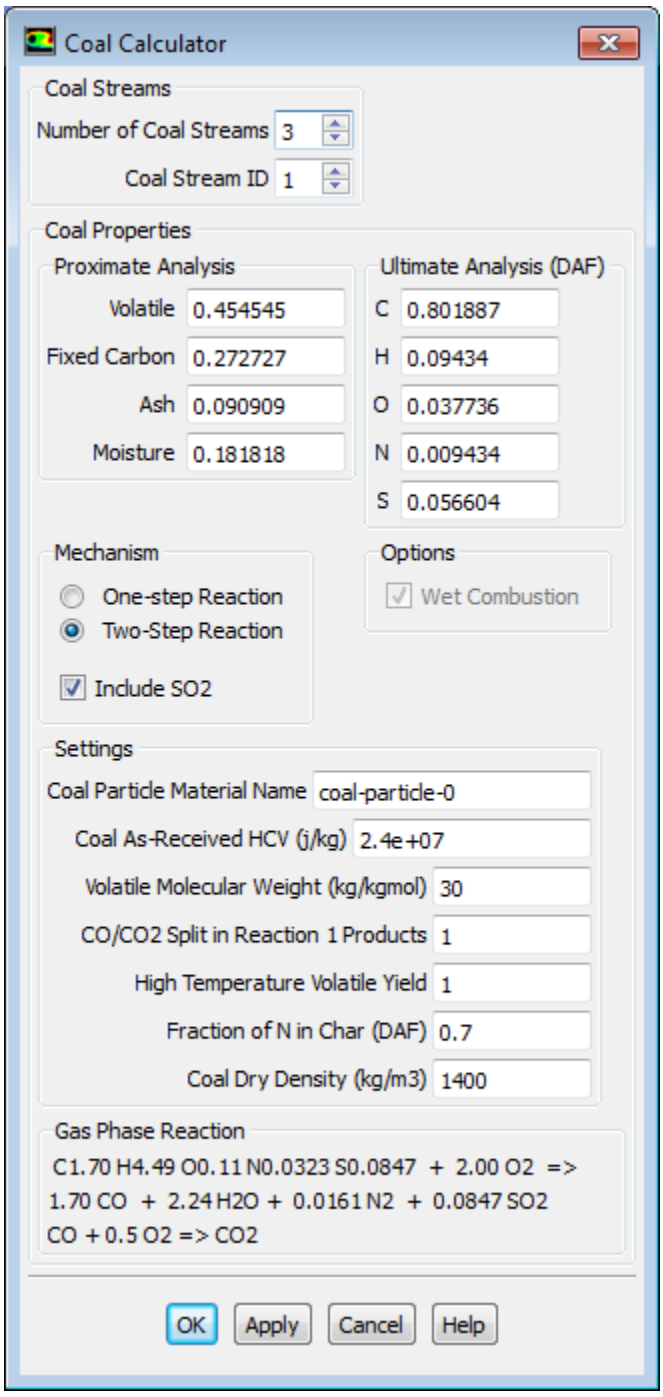
15.4.5.4. Postprocessing Non-Premixed Models of Coal Combustion

ANSYS Fluent reports the rate of volatile release from the coal using the **DPM Evaporation/Devolatilization** postprocessing variable. The rate of char burnout is reported in the **DPM Burnout** variable.

15.4.5.5. The Coal Calculator

The **Coal Calculator** dialog box automates the calculations described above for setting up a coal case from the proximate and ultimate analyses.

Figure 15.12: The Coal Calculator Dialog Box



The inputs to the **Coal Calculator** dialog box are:

1. Coal **Proximate Analysis**, which is the mass fraction of **Volatile, Fixed Carbon, Ash** and **Moisture** in the coal.

2. Coal **Ultimate Analysis**, which is the mass fraction of atomic **C, H, O, N** and optionally **S**, in the Dry-Ash-Free (DAF) coal.

3. The option to use a **Secondary Stream**. If enabled, the two mixture fraction model will be set with the primary stream representing char as $C<s>$, and an empirical secondary stream representing the volatiles.

4. The **Coal Particle Material Name**. A DPM Combusting Particle Material will be created with this name. The default name is *coal-particle*.

5. The **Coal As-Received HCV** (Higher Calorific Value).

6. The **High Temperature Volatile Yield**. Proximate analyses are generally done with slower heating rates and lower temperatures than would occur in a real flame. Therefore, enhanced devolatization at higher temperatures can cause the volatile yield to exceed the proximate analysis fraction. To model this, the actual volatile fraction used is calculated as that specified in the **Proximate Analysis** input multiplied by the **High Temperature Volatile Yield**. The actual **Fixed Carbon** fraction is then calculated as one minus the sum of the actual **Volatile**, **Ash**, and **Moisture** fractions.

7. **Fraction of N in Char (DAF)**. This input is used in calculating the split of atomic nitrogen for the Fuel NOx model.

   When the **OK** button is clicked, ANSYS Fluent makes the following changes:

   a. The empirical fuel atomic compositions in the **Boundary** tab are set, and the **Non-Adiabatic** model is enabled as required for DPM. The Empirical Fuel Lower Calorific Value is calculated as follows. First the DAF LCV of the coal is computed as,

   $$LCV_{coal}^{DAF} = \frac{HCV_{coal}^{ar} - h_{H_2O}^{latent} Moisture}{1 - Moisture - Ash} - \frac{H_{ar} W_{H_2O}}{2 W_H} h_{H_2O}^{latent} \tag{15.4}$$

   where $Moisture$ and Ash are the proximate moisture and ash fractions, H_{ar} is the ultimate H fraction, W_{H_2O} and W_H are the molecular weight of water and atomic hydrogen, respectively, and $h_{H_2O}^{latent}$ is the latent heat of water.

   If you are using the **Secondary Stream** option, LCV_{vol} is calculated from LCV_{coal}^{DAF} using,

   $$LCV_{vol} = \frac{LCV_{coal}^{DAF}\left(1 - Moisture - Ash\right) - LCV_{char} FixedCarbon}{Volatile} \tag{15.5}$$

   where $FixedCarbon$ and $Volatile$ are the proximate fixed carbon and volatile fractions, respectively.

   b. A combusting particle material is created with **Volatile Component Fraction** and **Combustible Fraction** calculated from the ultimate and proximate analyses. The Discrete Phase Model (DPM) is enabled.

   c. For the Fuel NOx model, the char N conversion is set to *NO*, and the Fuel NOx **Volatile** and **Char** mass fractions are set according to the ultimate and proximate compositions. Note that even though some of the Fuel NOx parameters are changed, the Fuel NOx model itself is not enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After the **Coal Calculator** has set up the relevant models, you must build the PDF Table by clicking **Calculate PDF Table** in the **Table** tab. You will also need to create injections if you have not done this yet. After converging your coal combustion case, you may want to enable the NOx model for postprocessing nitrogen-oxide pollutants.

15.5. Setting Up Control Parameters

For information about setting up control parameters, see the following sections:

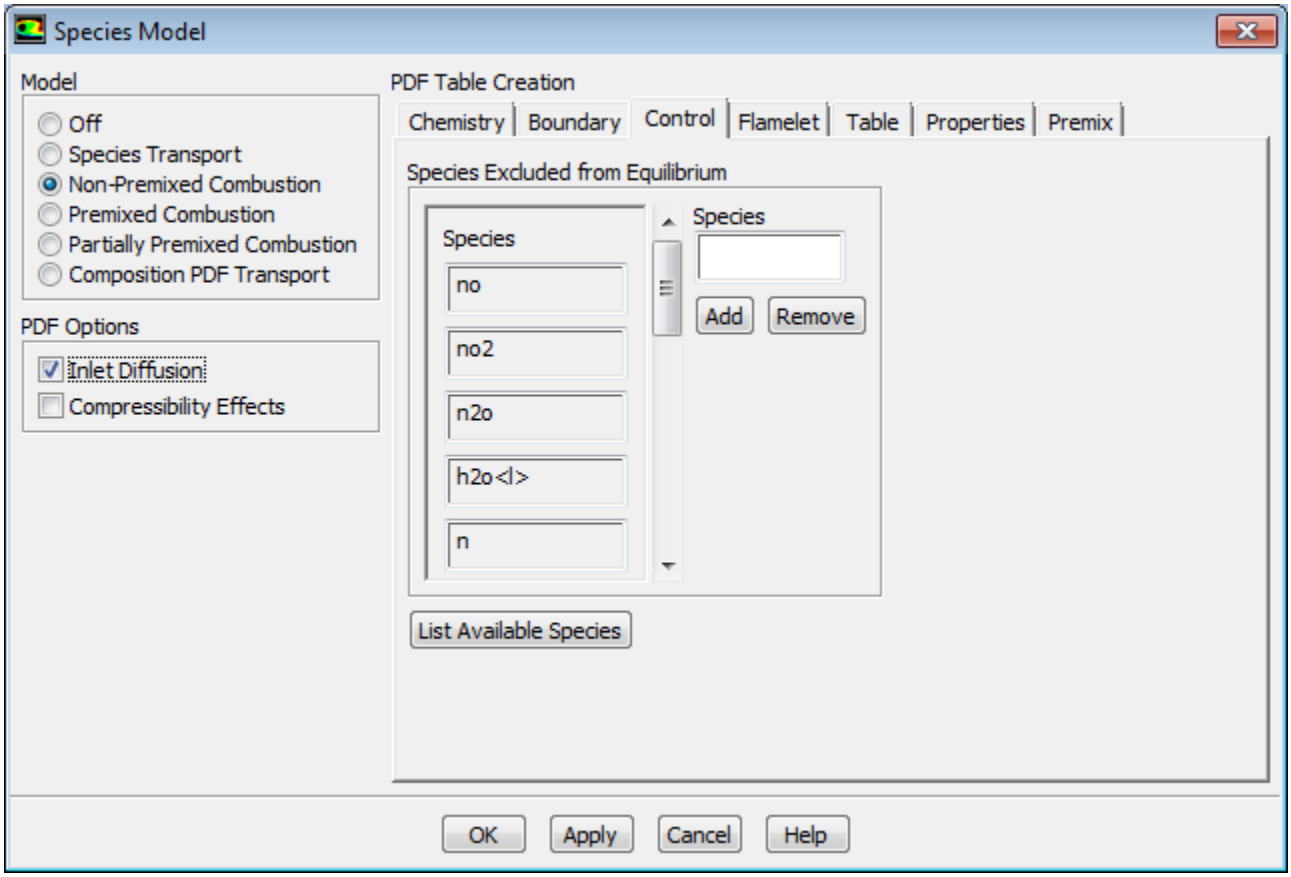
15.5.1. Forcing the Exclusion and Inclusion of Equilibrium Species
15.5.2. Defining the Flamelet Controls
15.5.3. Zeroing Species in the Initial Unsteady Flamelet

15.5.1. Forcing the Exclusion and Inclusion of Equilibrium Species

Because ANSYS Fluent calculates all intermediate and product species automatically during the equilibrium calculation, certain species will be included that are generally not in chemical equilibrium. Principal among these are the NOx species. Specifically, the NOx reaction rates are slow and should not be treated using an equilibrium assumption. Instead, the NOx concentration is predicted most accurately using the ANSYS Fluent NOx postprocessor, where finite-rate kinetics are included (see NOx Formation (p. 1153)). The NOx species can be safely excluded from the equilibrium calculation since they are present at low concentrations and have little impact on the density, temperature, and other species.

To force the exclusion of a species from the equilibrium calculation, click the **Control** tab in the **Species Model** dialog box (Figure 15.13: The Species Model Dialog Box (Control Tab) (p. 1053)).

Figure 15.13: The Species Model Dialog Box (Control Tab)



Under **Species Excluded From Equilibrium**, enter the chemical formula for the desired species in the **Add/Remove Species** field. Next, click **Add** to add the species to the **Species** list or **Remove** to remove an existing species from the **Species** list.

If there are species that you want to include in your PDF table that would be ignored by ANSYS Fluent due to their low concentration (for example, CH, CH_2, CH_3 for the NOx calculation), you can force ANSYS Fluent to include them using the text interface:

`define` → `models` → `species` → `non-premixed-combustion`

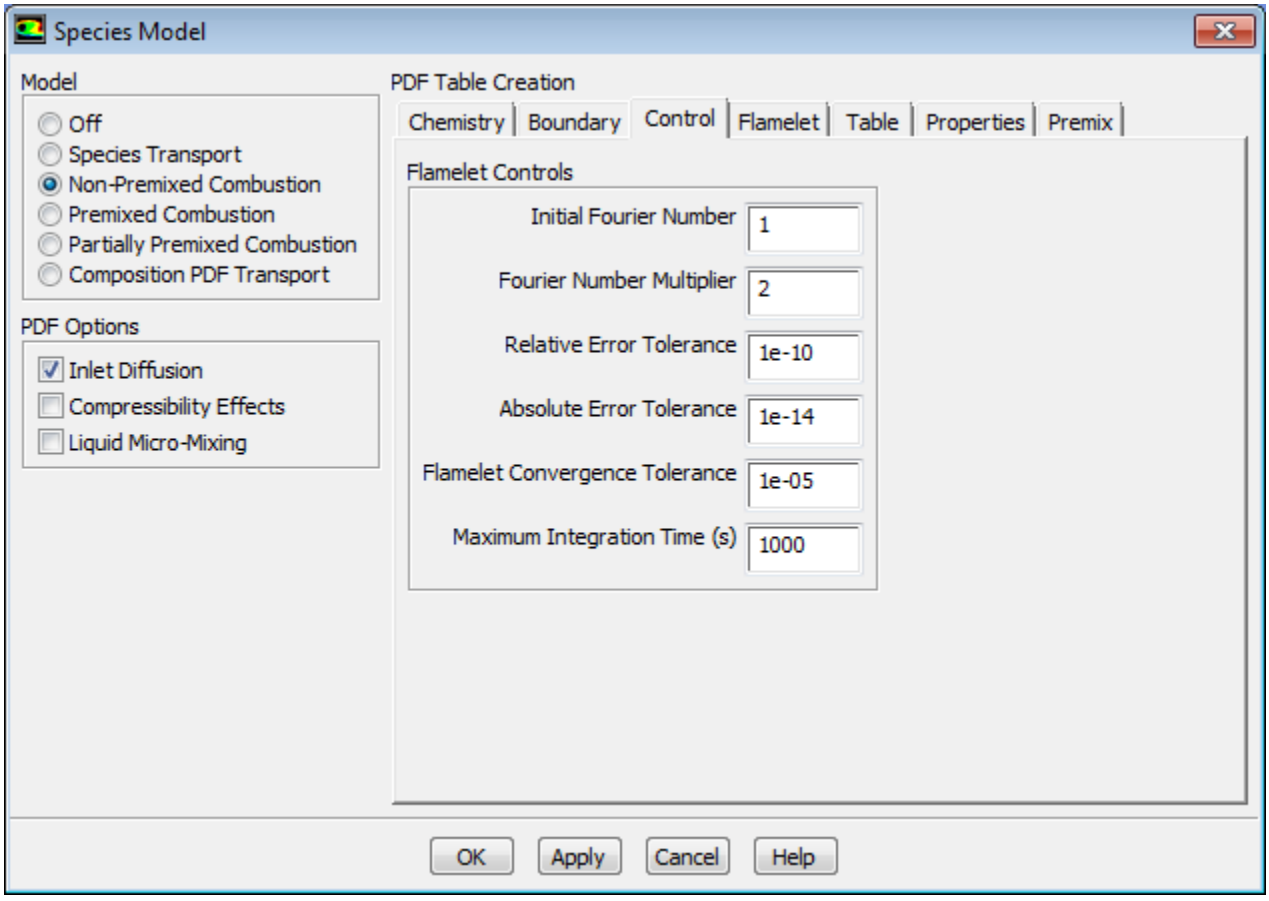
When the console window prompts you with `Force Equilibrium Species to Include...`, specify the appropriate species by entering the chemical formula(s) in double quotes (for example, `"ch"`, `"ch2"`).

Note that you will have to first set up the inputs for the fuel and oxidizer before you are given the option to include the species.

15.5.2. Defining the Flamelet Controls

When the steady diffusion flamelet model is selected, and you have created or imported a flamelet, you can adjust the controls for the flamelet solution in the **Control** tab of the **Species Model** dialog box (Figure 15.14: The Species Model Dialog Box (Control Tab) for the Steady Diffusion Flamelet Model (p. 1054)).

Figure 15.14: The Species Model Dialog Box (Control Tab) for the Steady Diffusion Flamelet Model



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Initial Fourier Number** sets the first time step for the solution of the flamelet equations (Equation 8.46 and Equation 8.47 in the Theory Guide). This first time step is calculated as the explicit stability-limited diffusion time step multiplied by this value. If the solution diverges before the first time step is complete, the value should be lowered.

The **Fourier Number Multiplier** increases the time step at subsequent times. Every time step after the first is multiplied by this value. If the solution diverges after the first time step, this value should be reduced.

During the numerical integration of the flamelet equations, the local error is controlled to be less than

$$error_{loc,i}=\varepsilon_{rel}\phi_i+\varepsilon_{abs} \tag{15.6}$$

where ϕ_i represents the species mass fractions and temperature at point i in the 1D flamelet. ε_{rel} is the value of the **Relative Error Tolerance** and ε_{abs} is the value of the **Absolute Error Tolerance**, both of which you can specify.

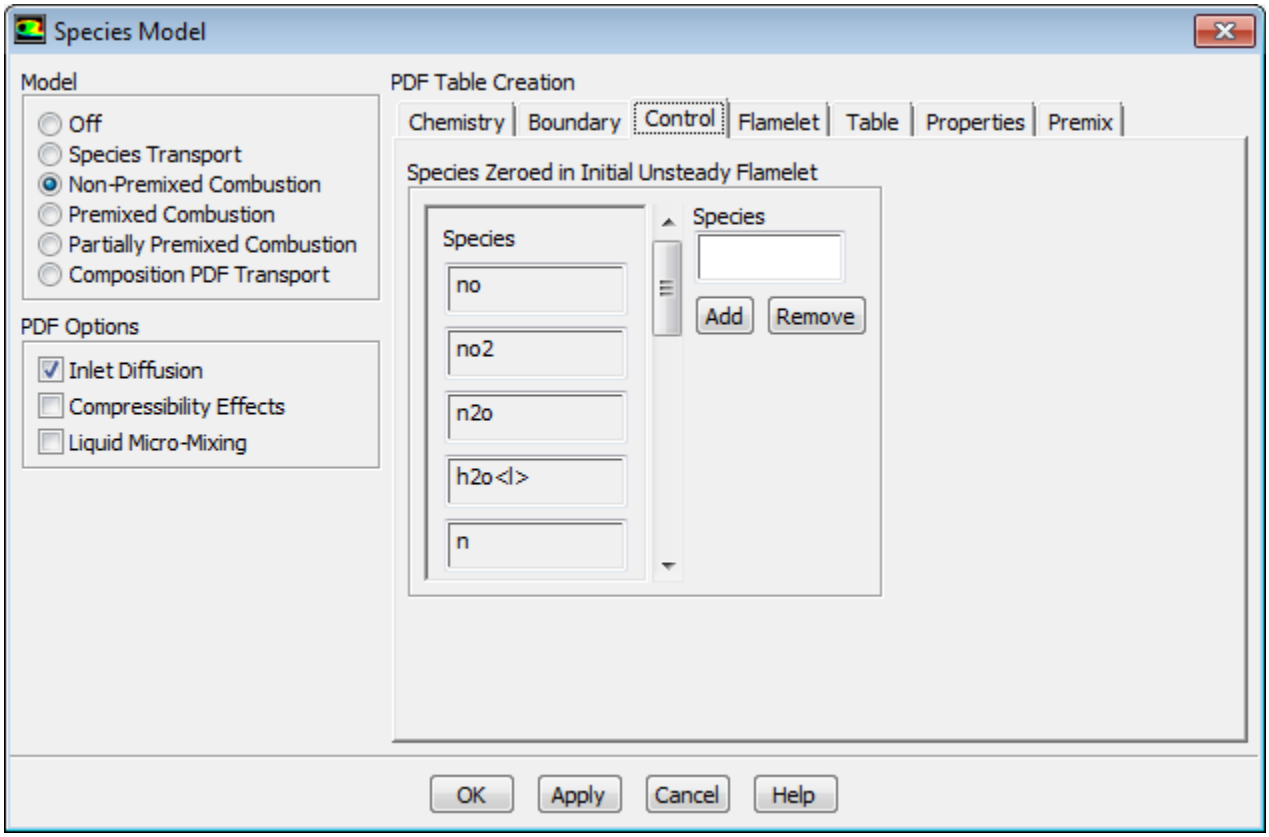
Because steady flamelets are obtained by time-stepping, they are considered converged only when the maximum absolute change in species fraction or temperature at any discrete mixture-fraction point is less than the specified **Flamelet Convergence Tolerance**. Between time steps, the flamelet species fractions and temperature will sometimes oscillate, which causes absolute changes that are always greater than the flamelet convergence tolerance. In such cases, ANSYS Fluent will stop the flamelet calculation after the total elapsed time has exceeded the **Maximum Integration Time**.

15.5.3. Zeroing Species in the Initial Unsteady Flamelet

When modeling gas-phase combustion using the Eulerian unsteady laminar flamelet model, the flamelet fields are initialized to a burning, steady-flamelet solution in order to model ignition. However, assuming steady-flamelet profiles for slow-forming species is inaccurate. A better approximation is to identify the slow species and to set them to zero, which is done in the **Control** tab. By default, ANSYS Fluent selects some NOx species (NO, NO_2, N_2O, N, NH, NH_2, NH_3, NNH, HCN, HNO, CN, $H2CN$, $HCNN$, $HCNO$, $HOCN$, $HNCO$, HCO), as well as liquid water H_2O<l> and solid carbon C<s> to be zeroed. See Figure 15.15: Method to Zero Out the Slow Chemistry Species (p. 1056).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.15: Method to Zero Out the Slow Chemistry Species



15.6. Calculating the Flamelets

For information about calculating flamelets, see the following sections:

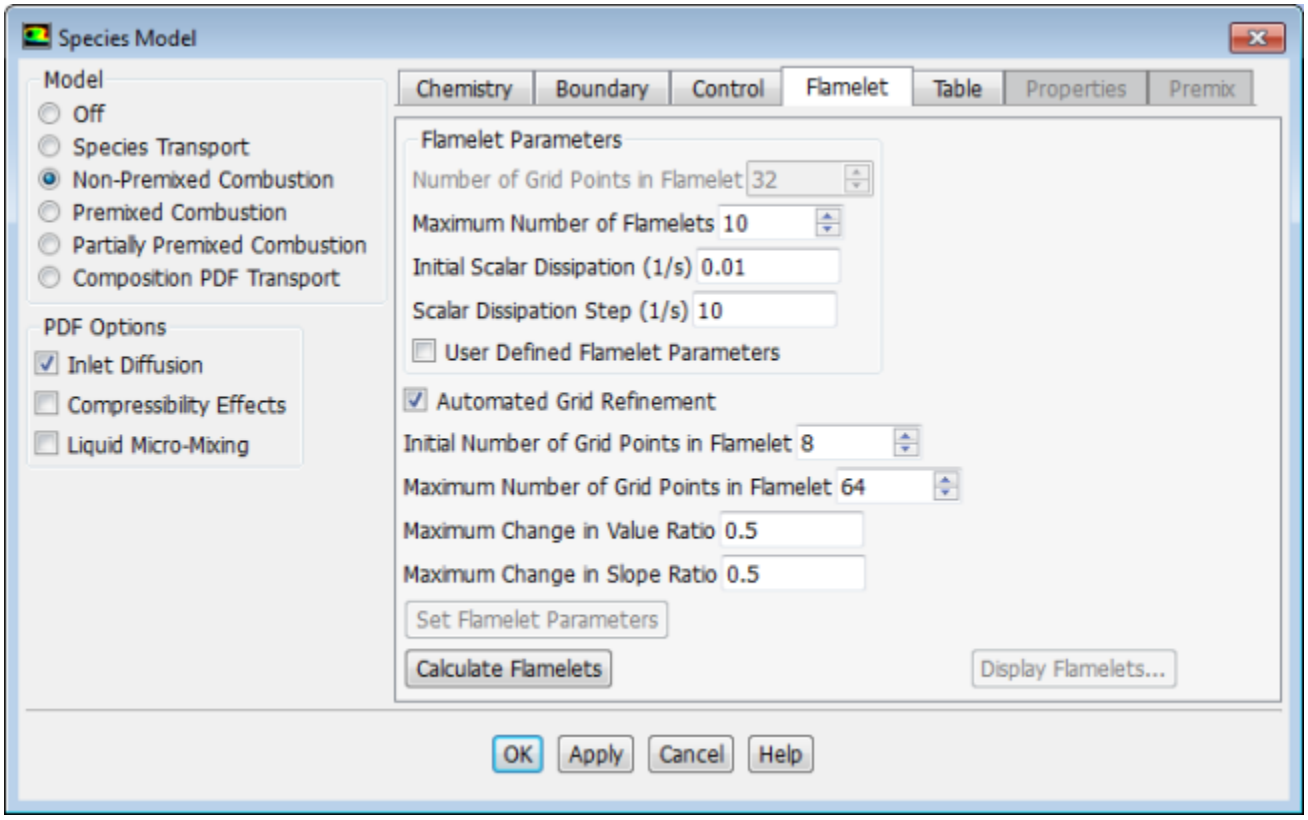
15.6.1. Steady Diffusion Flamelet
15.6.2. Unsteady Diffusion Flamelet
15.6.3. Saving the Flamelet Data
15.6.4. Postprocessing the Flamelet Data

15.6.1. Steady Diffusion Flamelet

In the **Flamelet** tab of the **Species Model** dialog box (Figure 15.16: The Species Model Dialog Box (Flamelet Tab) (p. 1057)), you will enter values for parameters of the flamelet(s).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.16: The Species Model Dialog Box (Flamelet Tab)



The **Flamelet Parameters** are as follows:

Number of Grid Points in Flamelet

specifies the number of mixture fraction grid points distributed between the oxidizer ($f=0$) and the fuel ($f=1$). Increased resolution will provide greater accuracy, but since the flamelet species and temperature are solved coupled and implicit in f space, the solution time and memory requirements increase greatly with the number of f grid points.

Maximum Number of Flamelets

specifies the maximum number of flamelet profiles to be calculated. If the flamelet extinguishes before this number is reached, flamelet generation is halted and the actual number of flamelets in the flamelet library will be less than this value.

Initial Scalar Dissipation

is the scalar dissipation of the first flamelet in the library. This corresponds to χ_0 in Equation 8.52 in the Theory Guide.

Scalar Dissipation Step

specifies the interval between scalar dissipation values (in s^{-1}) for which multiple flamelets will be calculated. This corresponds to $\Delta\chi$ in Equation 8.52 in the Theory Guide.

User Defined Flamelet Parameters

enables you to hook a user-defined function for scalar dissipation and mean mixture fraction (or progress variable) grid discretization

Automated Grid Refinement employs an adaptive algorithm, which inserts grid points so that the change of values, as well as the change of slopes, between successive grid points is less than user-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specified tolerances. For information about this option, refer to Steady Diffusion Flamelet Automated Grid Refinement in the Theory Guide.

Initial Number of Grid Points in Flamelet
calculates a steady solution on a coarse grid, with a default of 8. See Equation 8.53 in the Theory Guide.

Maximum Number of Grid Points in Flamelet
has a default of 64.

Maximum Change in Value Ratio
has a default of 0.5 and is ε_v in Equation 8.27 in the Theory Guide.

Maximum Change in Slope Ratio
has a default of 0.5 and is ε_s in Equation 8.28 in the Theory Guide.

Click **Calculate Flamelets** to begin the diffusion flamelet calculation. Sample output for a flamelet calculation is shown below.

```

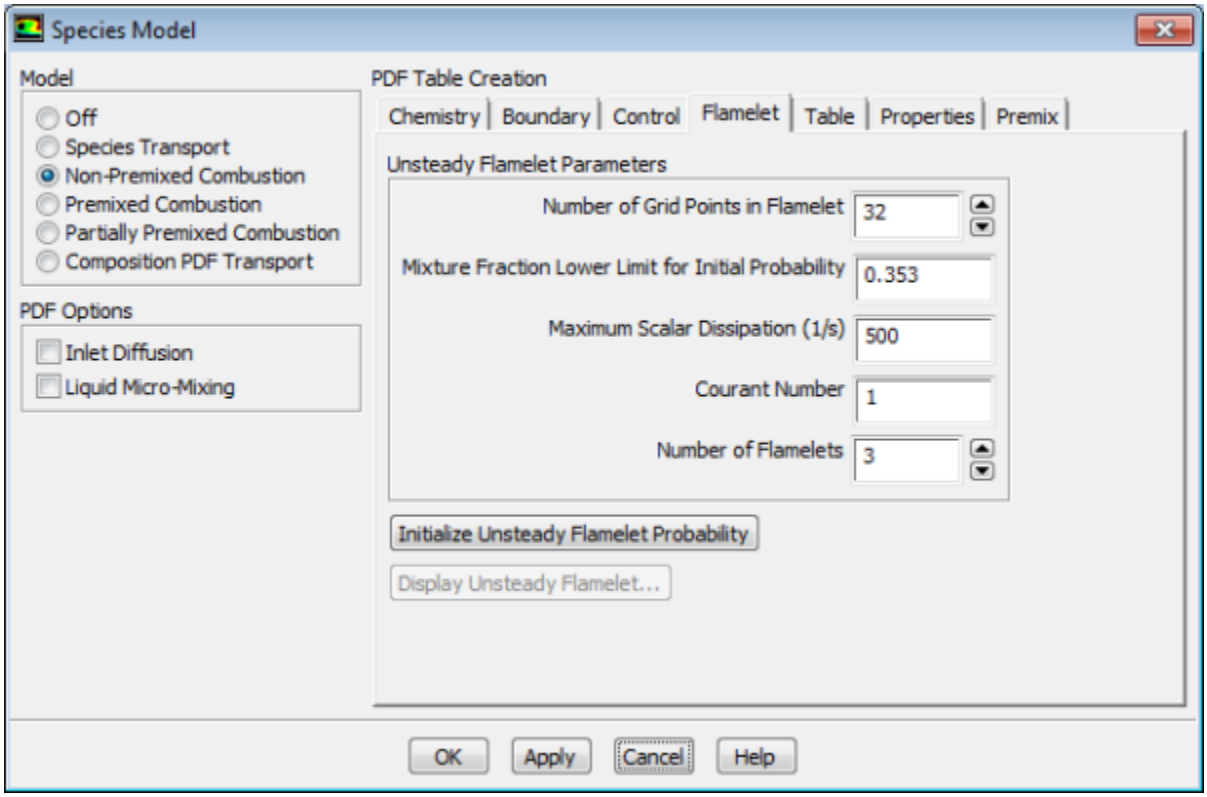
15.6.2. Unsteady Diffusion Flamelet

In the **Flamelet** tab of the **Species Model** dialog box (Figure 15.17: The Flamelet Tab for the Unsteady Diffusion Flamelet Model (p. 1059)), you will enter values for parameters of the flamelet.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.17: The Flamelet Tab for the Unsteady Diffusion Flamelet Model



The **Unsteady Flamelet Parameters** are as follows:

Number of Grid Points in Flamelet
specifies the number of mixture fraction grid points distributed between the oxidizer ($f=0$) and the fuel ($f=1$). Increased resolution will provide greater accuracy, but since the flamelet species and temperature are solved coupled and implicit in f space, the solution time and memory requirements increase with the number of f grid points.

Mixture Fraction Lower Limit for Initial Probability
is the mixture fraction above which the marker probability will be initialized to 1, and below which the marker probability will be initialized to 0. In general, it should be set greater than the stoichiometric mixture fraction.

Maximum Scalar Dissipation
is where flamelets extinguish at large scalar dissipation (mixing) rates. To prevent excessive mixing in the flamelet, ANSYS Fluent allows you to specify a **Maximum Scalar Dissipation** rate for the 1D flamelet equations. A reasonable value for this is the steady flamelet extinction scalar dissipation. The default value of 30/s is near the steady extinction scalar dissipation of a methane-air flame at standard temperature and pressure.

Courant Number
is the number at which ANSYS Fluent automatically selects the time step for the probability equation based on this convective Courant number.

Number of Flamelets
is the number of unsteady laminar flamelets to be initiated in the simulation. The probability marker equation will be solved for each flamelet.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Click **Initialize Unsteady Flamelet Probability** to initialize the unsteady flamelet and its probability marker equation. ANSYS Fluent is now ready for postprocessing the 1D unsteady flamelet and the 2D/3D unsteady marker probability equation.

15.6.3. Saving the Flamelet Data

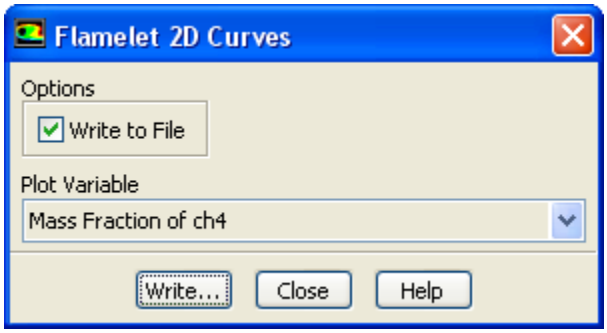
The flamelet tables may be written to file for import into later sessions of ANSYS Fluent. You may want to do this, for example, to change the number of discretization points in the PDF table, or to plot the flamelet profiles in ANSYS Fluent. The flamelet tables should be saved before you create the PDF table:

File → **Write** → **Flamelet...**

15.6.4. Postprocessing the Flamelet Data

For the flamelet model, you can display or write flamelet curves. Click the **Display Flamelets...** or **Display Unsteady Flamelet...** button. If you have a single flamelet, as for the unsteady diffusion flamelet model, you can access the **Flamelet 2D Curves** dialog box (Figure 15.18: The Flamelet 2D curves Dialog Box (p. 1060)).

Figure 15.18: The Flamelet 2D curves Dialog Box

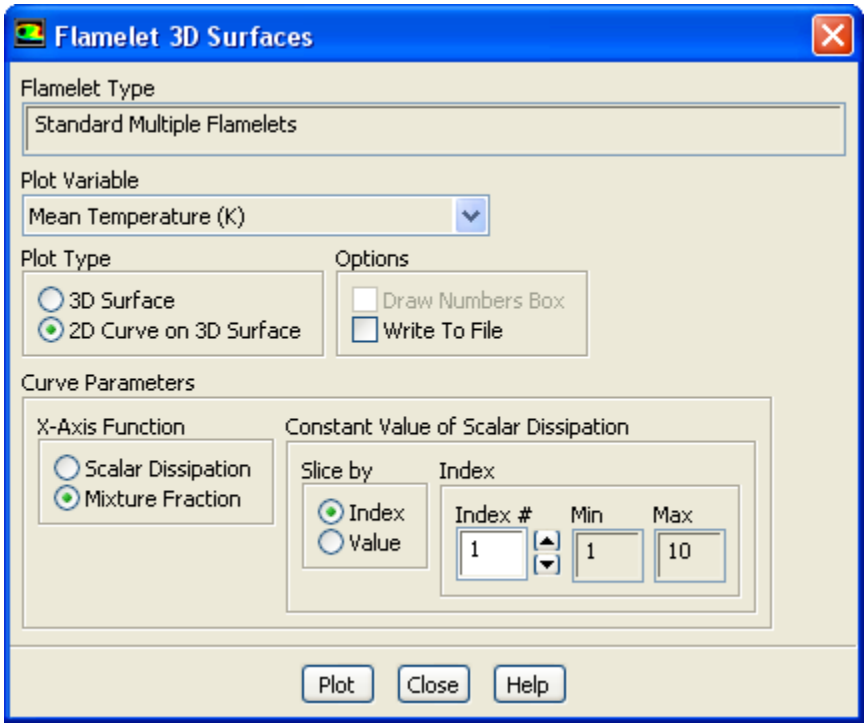


For the steady diffusion flamelet model with more than one flamelet, you can display 2D plots and 3D surfaces showing the variation of species fraction or temperature with the mean mixture fraction or scalar dissipation using the **Flamelet 3D Surfaces** dialog box (for example, Figure 15.19: The Flamelet 3D Surfaces Dialog Box (p. 1061)).

To access this dialog box, click the **Display Flamelets...** button in the **Flamelet** tab of the **Species Model** dialog box, as shown in Figure 15.16: The Species Model Dialog Box (Flamelet Tab) (p. 1057).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.19: The Flamelet 3D Surfaces Dialog Box



To display the flamelet tables graphically, use the following procedure:

1. In the **Flamelet 3D Surfaces** dialog box, from the **Plot Variable** drop-down list, select the variable you want to display graphically.

2. Specify the **Plot Type** as either **3D Surface** or **2D Curve on 3D Surface**.

   - For a 3D surface, enable or disable **Draw Numbers Box** under **Options**. When this option is turned on, the display will include a wireframe box with the numerical limits in each coordinate direction.

   - For a 2D curve on a 3D surface:

     a. Specify whether you want to write the plot data to a file by toggling **Write To File** under **Options**.

     b. Specify the **X-Axis Function** against which the plot variable will be displayed by selecting **Scalar Dissipation** (χ), or **Mixture Fraction** (f). The variable that is not selected will be held constant.

     c. Specify the type of discretization (that is, how the flamelet data will be sliced) for the variable that is being held constant (under **Constant Value of Mixture Fraction** or **Constant Value of Scalar Dissipation**).

        – If you selected **Index** under **Slice by**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Flamelet** tab of the **Species Model** dialog box (see Calculating the Flamelets (p. 1056)).

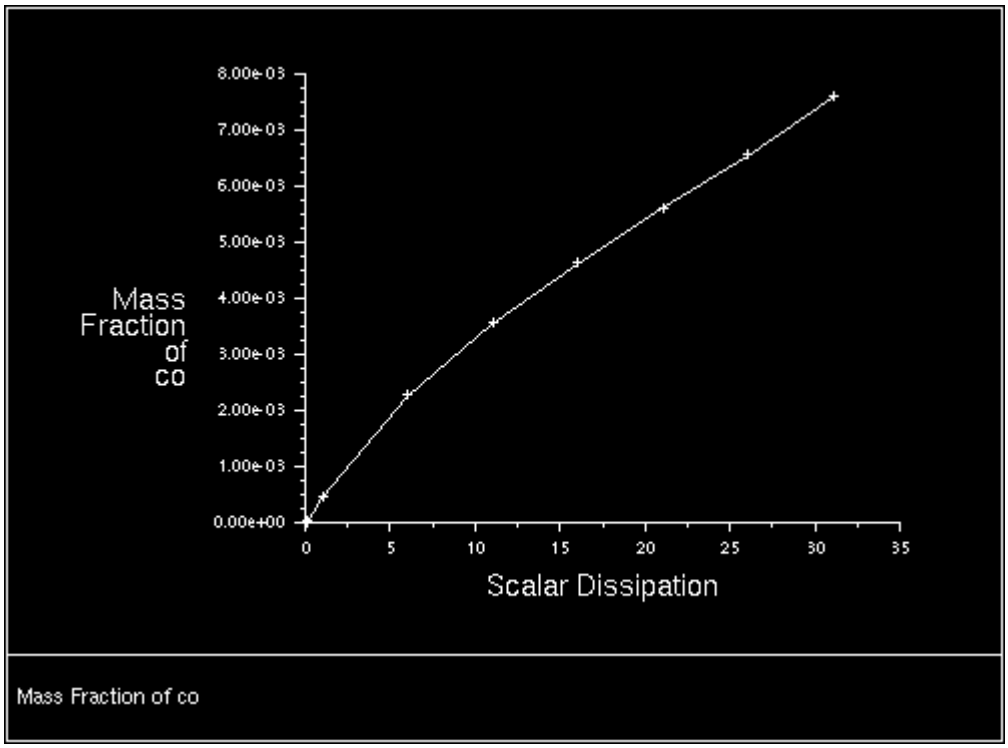
        – If you selected **Value** under **Slice by**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Write or display the flamelet table results. If you have turned on the **Write To File** option for a 2D plot, click **Write** and specify a name for the file in The Select File Dialog Box (p. 19). Otherwise, click **Plot** or **Display** as appropriate to display a 2D plot or 3D surface in the graphics window.

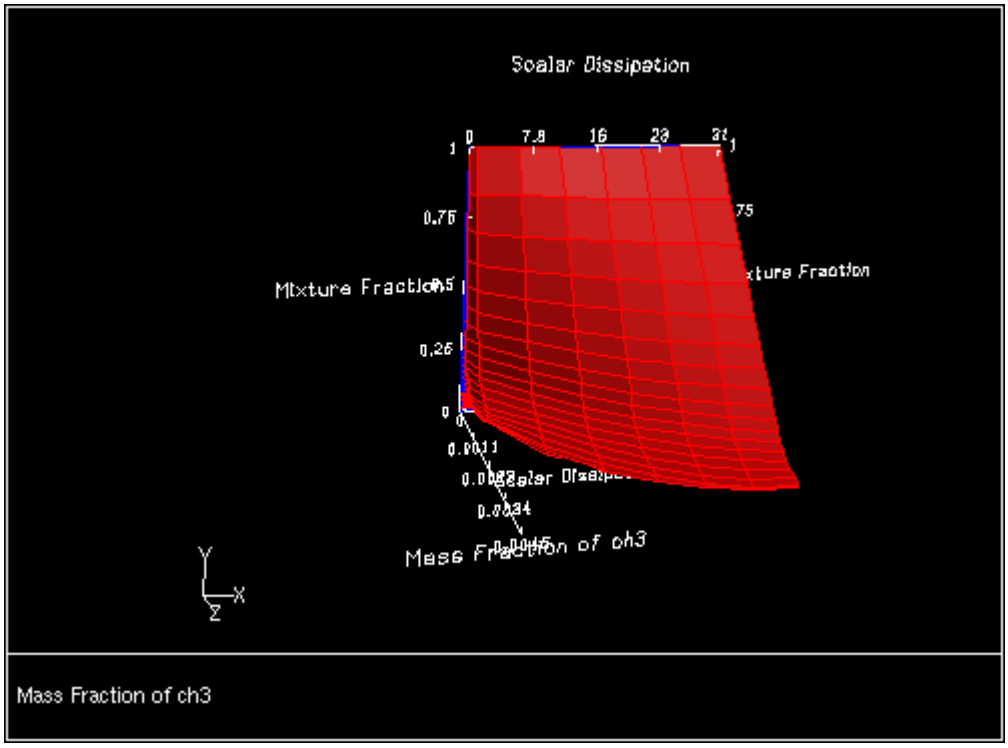
Figure 15.20: Example 2D Plot of Flamelet Data (p. 1062) and Figure 15.21: Example 3D Plot of Flamelet Data (p. 1063) show examples of a 2D curve plot and 3D surface plot of a flamelet table.

Figure 15.20: Example 2D Plot of Flamelet Data



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.21: Example 3D Plot of Flamelet Data



15.7. Calculating the Look-Up Tables

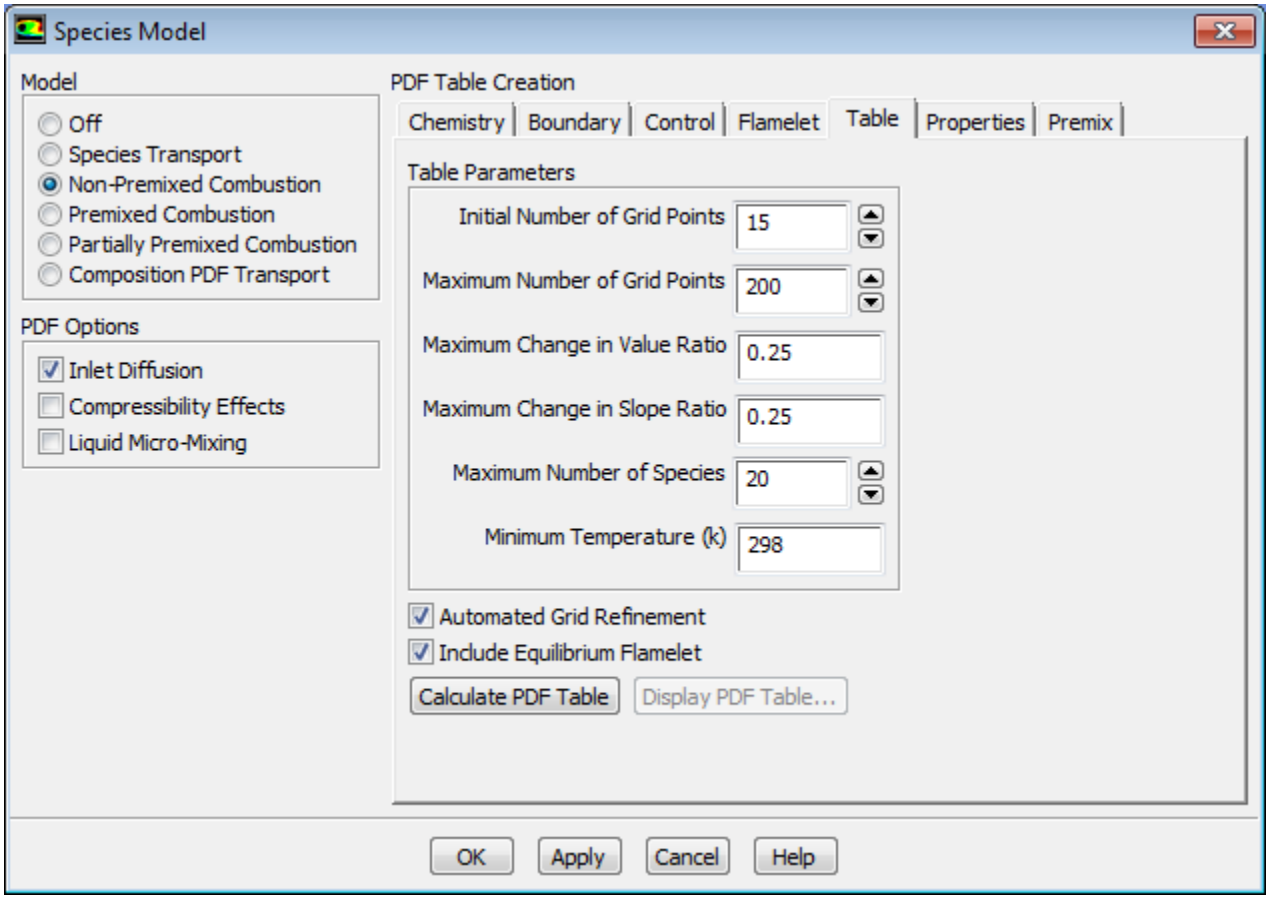
ANSYS Fluent requires additional inputs that are used in the creation of the look-up tables. Several of these inputs control the number of discrete values for which the look-up tables will be computed. These parameters are input in the **Table** tab of the **Species Model** dialog box. When **Automated Grid Refinement** is enabled, you will specify the table parameters displayed in Figure 15.22: The Species Model Dialog Box (Table) Tab Displaying Automated Grid Refinement (p. 1064). If **Automated Grid Refinement** is disabled, you will specify the table parameters displayed in Figure 15.23: The Species Model Dialog Box (Table) Tab Excluding Automated Grid Refinement (p. 1065).

Note

Automated Grid Refinement is not available with two mixture fractions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.22: The Species Model Dialog Box (Table) Tab Displaying Automated Grid Refinement



The look-up table parameters when **Automated Grid Refinement** is enabled are as follows:

Initial Number of Grid Points
specifies the number of grid points for the resolution of the mean mixture fraction, mixture fraction variance, and mean enthalpy (for non-adiabatic systems).

Maximum Number of Grid Points
specifies the maximum number of grid points used for tabulation. The grid refinement procedure will stop inserting the points when either the change in value and slope between successive points is within tolerance or the maximum number of grid points are generated.

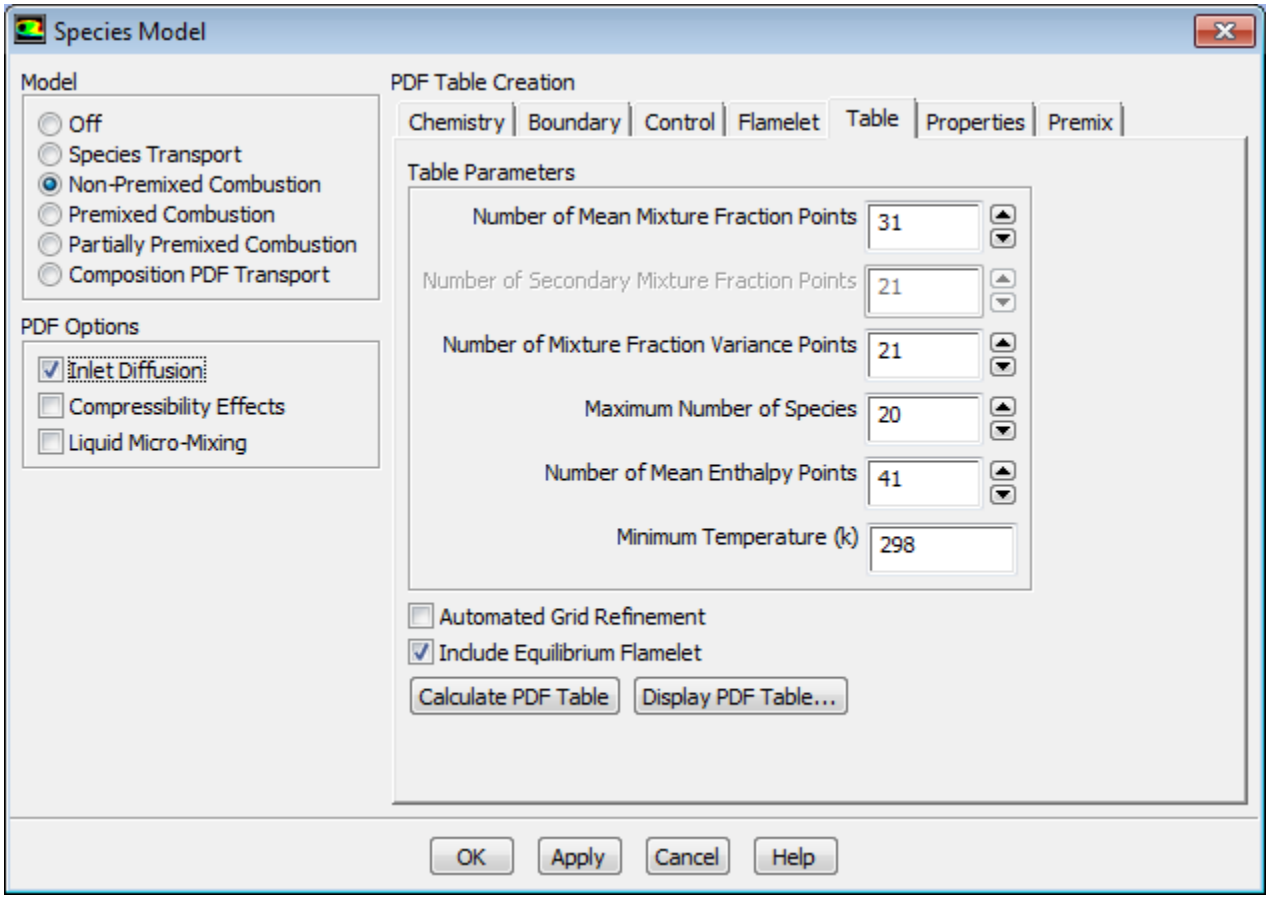
Maximum Change in Value Ratio
specifies the maximum allowable change in value of table variables between successive grid points as specified by Equation 8.27 in the Theory Guide.

Maximum Change in Slope Ratio
specifies the maximum change in the slope of table variables between successive grid points as specified by Equation 8.28 in the Theory Guide.

Maximum Number of Species
is the maximum number of species stored in the lookup tables.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 15.23: The Species Model Dialog Box (Table) Tab Excluding Automated Grid Refinement



The look-up table parameters when **Automated Grid Refinement** is disabled are as follows:

Number of Mean Mixture Fraction Points

is the number of discrete values of $\overline{f}$ at which the look-up tables will be computed. For a two-mixture-fraction model, this value is the number of points in the instantaneous state profile used to compute the PDF if you choose the β PDF model (see Tuning the PDF Parameters for Two-Mixture-Fraction Calculations (p. 1084)). Increasing the number of points will yield a more accurate PDF shape, but the calculation will take longer. The mean mixture fraction points will be automatically clustered around the stoichiometric mixture fraction value.

Number of Mixture Fraction Variance Points

is the number of discrete values of $\overline{f'^2}$ at which the look-up tables will be computed. Lower resolution is acceptable because the variation along the $\overline{f'^2}$ axis is, in general, slower than the variation along the $\overline{f}$ axis of the look-up tables. This option is available only when no secondary stream has been defined.

Number of Secondary Mixture Fraction Points

is the number of discrete values of p_{sec} at which the look-up tables will be computed. Like the **Number of Mean Mixture Fraction Points**, ANSYS Fluent will use the **Number of Secondary Mixture Fraction Points** to compute the equilibrium state-relation if you choose the β PDF option (see Tuning the PDF Parameters for Two-Mixture-Fraction Calculations (p. 1084)) for a two-mixture-fraction model. A larger number of points will give a more accurate shape for the PDF, but with a longer calculation time. This option is available only when a secondary stream has been defined.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Maximum Number of Species

is the maximum number of species that will be included in the look-up tables. The maximum number of species that can be included is 200. ANSYS Fluent will automatically select the species with the largest mole fractions to include in the PDF table. Note that the PDF table values of density and specific heat are pre-calculated with all the species, and hence the convergence behavior of ANSYS Fluent will not be affected by the input for the **Maximum Number of Species**. Hence, to keep table sizes small, you should set the **Maximum Number of Species** to only include the species that you are interested in postprocessing.

Number of Mean Enthalpy Points

is the number of discrete values of enthalpy at which the look-up tables will be computed. This input is required only if you are modeling a non-adiabatic system. The number of points required will depend on the chemical system that you are considering, with more points required in high heat release systems (for example, hydrogen/oxygen flames). This option is not available with the unsteady flamelet model.

Minimum Temperature

is used to determine the lowest temperature for which the look-up tables are generated. Your input should correspond to the minimum temperature expected in the domain (for example, an inlet or wall temperature). The minimum temperature should be set 10–20 K below the minimum system temperature. This option is available only if you are modeling a non-adiabatic system. This option is not available with the unsteady flamelet model.

Include Equilibrium Flamelet

specifies that an equilibrium flamelet (that is, $\chi=0$) will be generated in ANSYS Fluent and appended to the flamelet library before the PDF table is calculated. This option is available when generating or importing multiple flamelets, as well as when a single flamelet is considered. In the latter case, the PDF table will consist of two scalar dissipation slices, namely the equilibrium slice at $\chi=0$, and the flamelet slice. This option is not available with the equilibrium chemistry model or the unsteady diffusion flamelet model.

When you are satisfied with your inputs, click **Calculate PDF Table** to generate the look-up tables.

The computations performed for a single-mixture-fraction calculation culminate in the discrete integration of Equation 8.16 (or Equation 8.24 in the Theory Guide) as represented in Figure 8.5: Logical Dependence of Averaged Scalars on Mean Mixture Fraction, the Mixture Fraction Variance, and the Chemistry Model (Adiabatic, Single-Mixture-Fraction Systems) (or Figure 8.6: Logical Dependence of Averaged Scalars on Mean Mixture Fraction, the Mixture Fraction Variance, Mean Enthalpy, and the Chemistry Model (Non-Adiabatic, Single-Mixture-Fraction Systems) in the Theory Guide). For a two-mixture-fraction calculation, ANSYS Fluent will calculate the physical properties using Equation 8.14 or its adiabatic equivalent. The computation time will be shortest for adiabatic single-mixture-fraction equilibrium calculations and longest for non-adiabatic calculations involving multiple flamelet generation. Below, sample outputs are shown for an adiabatic single-mixture-fraction equilibrium calculation and a non-adiabatic calculation with flamelets:

```
Generating PDF lookup table

 PDF Table successfully generated!
Initializing PDF table arrays and structures.
```

Important

Note that there is a significant difference in run time between the one-mixture fraction model and the two-mixture fraction model. In the one-mixture fraction model, the PDF table contains the mean data of density, temperature, and specific heats, and is three-dimensional for an equilibrium nonadiabatic case (mean mixture fraction, mixture fraction variance, and mean heat loss). For this case, ANSYS Fluent updates properties every flow iteration. In the case of the two-mixture fraction model, only the instantaneous state relationships are stored and mean properties are calculated from these by performing PDF integrations in every cell of the ANSYS Fluent simulation. Since this is computationally expensive, ANSYS Fluent provides the option of only updating properties after a specified number of iterations.

For a two-mixture fraction model, you can also refer to Full Tabulation of the Two-Mixture-Fraction Model (p. 1067) for more information.

After completing the calculation at the specified number of mixture fraction points, ANSYS Fluent reports that the calculation succeeded. In a single-mixture-fraction case, the resulting look-up tables take the form illustrated in Figure 8.8: Visual Representation of a Look-Up Table for the Scalar (Mean Value of Mass Fractions, Density, or Temperature) as a Function of Mean Mixture Fraction and Mixture Fraction Variance in Adiabatic Single-Mixture-Fraction Systems in the Theory Guide (or Figure 8.10: Visual Representation of a Look-Up Table for the Scalar as a Function of Mean Mixture Fraction and Mixture Fraction Variance and Normalized Heat Loss/Gain in Non-Adiabatic Single-Mixture-Fraction Systems, for non-adiabatic systems). These look-up tables can be plotted using the available graphics tools, as described in Postprocessing the Look-Up Table Data (p. 1068).

Note that in non-adiabatic calculations, the console window will report that the temperature limits and enthalpy slices have been calculated.

For a two-mixture-fraction case, the resulting look-up tables take the form illustrated in Figure 8.9: Visual Representation of a Look-Up Table for the Scalar ϕ_I as a Function of Fuel Mixture Fraction and Secondary Partial Fraction in Adiabatic Two-Mixture-Fraction Systems in the Theory Guide (or Figure 8.11: Visual Representation of a Look-Up Table for the Scalar ϕ_I as a Function of Fuel Mixture Fraction and Secondary Partial Fraction, and Normalized Heat Loss/Gain in Non-Adiabatic Two-Mixture-Fraction Systems, for non-adiabatic systems).

15.7.1. Full Tabulation of the Two-Mixture-Fraction Model

The default algorithm for the two-mixture-fraction model is to perform PDF integrations of the equilibrium state relationships at run time. Since these are multi-dimensional integrals, the default two-mixture-fraction model can be computationally demanding.

Alternatively, you may want to pre-compute these integrations and create 4D look-up tables for adiabatic simulations, or 5D tables for non-adiabatic simulations. Such high-dimensional tables are computationally expensive to build, and may require large memory and disk storage, but can offer substantial improvement in run time speed.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The option to create a fully-tabulated two-mixture-fraction table is available in cases with the two-mixture-fraction model enabled, via the text command:

```
define/models/species/full-tabulation?
```

If you are modeling pollutant formation, note that the full tabulation option is not compatible with the **mixture-fraction** option for **PDF Mode** in the **Turbulence Interaction Mode** tab settings. See Setting Turbulence Parameters (p. 1166) for details on Turbulence Interaction options for pollutant modeling.

15.7.2. Stability Issues in Calculating Chemical Equilibrium Look-Up Tables

Complex chemistry and non-adiabatic effects may make the equilibrium calculation more time-consuming and difficult. In some instances the equilibrium calculation may even fail. You may be able to eliminate any difficulties that you encounter by trying the calculation as an adiabatic system. Adiabatic system calculations are generally quite straightforward and can provide valuable insight into the optimal inputs to the non-adiabatic calculation.

Additional stability issues may arise for solid or heavy liquid fuels that have been defined using the empirical fuel approach. You may find that, for rich fuel mixtures, the equilibrium calculation produces very low temperatures and eventually fails. This indicates that strong endothermic reactions are taking place and the mixture is not able to sustain them. In this situation, you may need to raise the heating value of the fuel until ANSYS Fluent produces acceptable results. Provided that your fuel will be treated as a liquid or solid (coal) fuel, you can maintain the desired heating value in your ANSYS Fluent simulation. This is accomplished by defining the difference between the desired and the adjusted heating values as latent heat (in the case of combusting solid fuel) or heat of pyrolysis (in the case of liquid fuel).

15.7.3. Saving the Look-Up Tables

The look-up tables may be stored in a file that you can read back into later sessions of ANSYS Fluent. The look-up tables should be saved before you exit from the current ANSYS Fluent session.

File → **Write** → **PDF...**

By default, the file will be saved as formatted (ASCII, or text). To save a binary (unformatted) file, turn on the **Write Binary Files** option in the **Select File** dialog box.

15.7.4. Postprocessing the Look-Up Table Data

It is important for you to view your temperature and species tables to ensure that they are adequately but not excessively resolved. Inadequate resolution will lead to inaccuracies, and excessive resolution will lead to unnecessarily slow calculation times.

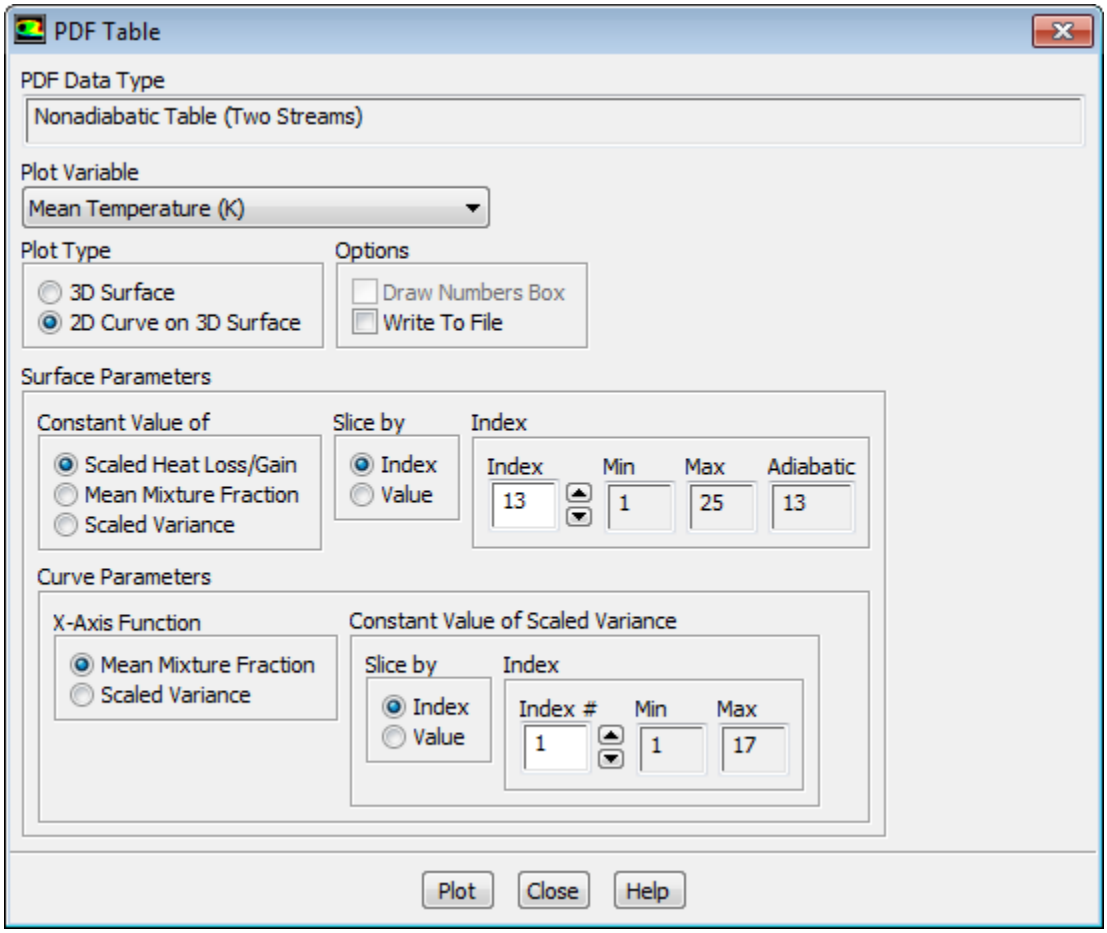
After a PDF table has been generated or read into ANSYS Fluent, you can display 2D plots and 3D surfaces showing the variation of species mole fraction, density, or temperature with the mean mixture fraction, mixture fraction variance, or enthalpy using the **PDF Table** dialog box (for example, Figure 15.24: The PDF Table Dialog Box (Non-Adiabatic Case With Flamelets) (p. 1069)). The **PDF Table** dialog box can be accessed in one of two ways:

- by clicking the **Display PDF Table...** button in the **Table** tab of the **Species Model** dialog box (as shown in Figure 15.23: The Species Model Dialog Box (Table) Tab Excluding Automated Grid Refinement (p. 1065))
- by using the following path:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Postprocessing → Model Specific → PDF Table...

Figure 15.24: The PDF Table Dialog Box (Non-Adiabatic Case With Flamelets)



To display the look-up tables graphically, use the following procedure:

1. In the **PDF Table** dialog box, in the **Plot Variable** drop-down list you can select temperature, density, or species mole fraction as the variable to be plotted.

2. (multiple flamelets only) Specify the value of the **Scalar Dissipation**. In the case of non-adiabatic flamelets, there is the additional parameter of mean enthalpy. In addition to varying the mean enthalpy and mean mixture fraction, you can vary the display of the PDF table by changing the value of the scalar dissipation, which gives the table a fourth "dimension".

3. Specify the **Plot Type** as either **3D Surface** or **2D Curve on 3D Surface**. In the equilibrium model, a 2D curve is a slice of a 3D surface, and therefore some options selected for a 3D surface may impact the display of a 2D curve.

   - For a 3D surface:

     a. Enable or disable **Draw Numbers Box** under **Options**. When this option is turned on, the display will include a wireframe box with the numerical limits in each coordinate direction.

     b. (non-adiabatic cases only) Under **Surface Parameters**, specify the discrete independent variable to be held constant in the look-up table (**Constant Value of**).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– For a single-mixture-fraction case, select **Scaled Heat Loss/Gain** ($\overline{H}$), **Mean Mixture Fraction** ($\overline{f}$), or **Scaled Variance** ($\overline{f'^2}$). For any mean mixture fraction $\overline{f}$, the variance varies between a minimum of 0 and a maximum of $\overline{f}\left(1-\overline{f}\right)$. In order to view the mixture fraction variance, it is normalized by Equation 15.7 (p. 1070) so that for any mean mixture fraction the scaled variance ranges from 0 to 0.25.

$$\overline{f_s'^2}=0.25\frac{\overline{f'^2}}{\overline{f}\left(1-\overline{f}\right)} \tag{15.7}$$

– For a two-mixture-fraction case, the **Scaled Heat Loss/Gain** is the only available option.

c. (non-adiabatic cases only) Specify whether the 3D array of data points available in the look-up table will be sliced by **Index** or **Value** under **Slice by**.

– If you selected **Index**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Table** tab of the **Species Model** dialog box (see Calculating the Look-Up Tables (p. 1063)). If you specified to hold the enthalpy (**Scaled Heat Loss/Gain**) constant, the enthalpy slice index corresponding to the adiabatic case will be displayed in the **Adiabatic** field.

– If you selected **Value**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.

- For a 2D curve on a 3D surface:

a. Specify whether you want to write the plot data to a file by toggling **Write To File** under **Options**.

b. Under **Curve Parameters**, specify the **X-Axis Function** against which the plot variable will be displayed.

– For an adiabatic single-mixture-fraction case, select **Mean Mixture Fraction** ($\overline{f}$), or **Scaled Variance** ($\overline{f'^2}$).

– For a non-adiabatic single-mixture-fraction case, the options will depend on what was selected under **Constant Value of** under **Surface Parameters**, but will include two of the following: **Scaled Heat Loss/Gain** ($\overline{H}$), **Mean Mixture Fraction**, and **Scaled Variance**.

– For a two-mixture-fraction case, select **Fuel Mixture Fraction** (f_{fuel}) or **Secondary Partial Fraction** (p_{sec}).

c. Specify the type of discretization (that is, how the look-up table data will be sliced) for the variable that is being held constant (under **Constant Value of Mean Mixture Fraction**, **Constant Value of Scaled Variance**, and so on). Note that for non-adiabatic cases, each 3D surface slice contains a full set of 2D slices.

– If you selected **Index** under **Slice by**, specify the discretization **Index** of the variable that is being held constant. The range of integer values that you are allowed to choose from is displayed under **Min** and **Max**, and is equivalent to the number of points specified for that variable in the **Table** tab of the **Species Model** dialog box (see Calculating the Look-Up Tables (p. 1063)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– If you selected **Value** under **Slice by**, specify the numerical **Value** of the variable that is being held constant. The range of values that you can specify is displayed under **Min** and **Max**.

4. Write or display the look-up table results. If you have turned on the **Write To File** option for a 2D plot, click **Write** and specify a name for the file in The Select File Dialog Box (p. 19). Otherwise, click **Plot** or **Display** as appropriate to display a 2D plot or 3D surface in the graphics window.

Figure 15.25: Mean Species Mole Fraction Derived From an Equilibrium Chemistry Calculation (p. 1071) and Figure 15.26: Mean Temperature Derived From an Equilibrium Chemistry Calculation (p. 1072) show examples of 2D plots derived for a very simple hydrocarbon system.

15.8. Standard Files for Diffusion Flamelet Modeling

The standard flamelet file format can be used to read and write non-premixed (diffusion) flamelets. The data structure for the standard flamelet file format is based on keywords that precede each data section. If any of the keywords in your flamelet data file do not match the supported keywords, you will have to manually edit the file and change the keywords to one of the supported types. (The ANSYS Fluent flamelet filter is case-insensitive, so you need not worry about capitalization within the keywords.)

The following keywords are supported by the ANSYS Fluent filter:

Description	Keyword
Header section	HEADER
Main body section	BODY
Number of species	NUMOFSPECIES
Number of grid points	GRIDPOINTS
Pressure	PRESSURE
Strain rate for diffusion flamelet generated in physical space	STRAINRATE
Stoichiometric scalar dissipation for diffusion flamelet	STOICH_SCADIS or CHI
Stoichiometric mixture fraction	STOICH_Z
Temperature	TEMPERATURE and TEMP
Mass fraction	MASSFRACTION-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Description	Keyword
Mixture fraction	Z
Mole fraction	MOLEFRACTION-

Note

The strain rate output is written if the flamelets are generated in physical space, for example, using ANSYS CHEMKIN.

15.8.1. Sample Standard Diffusion Flamelet File

A sample diffusion flamelet file in the standard format is provided below. Note that not all species are listed in this file.

15.8.2. Missing Species

ANSYS Fluent will check whether all species in the flamelet data file exist in the thermodynamic properties databases `thermo.db`. If any of the species in the flamelet file do not exist, ANSYS Fluent will issue an error message and halt the flamelet import. If this occurs, you can either add the missing species to the database, or remove the species from the flamelet file.

You should not remove a species from the flamelet data file unless its species concentration is very small (10^{-3} or less) throughout the flamelet profile. If you remove a low-concentration species, you will not have the species concentrations available for viewing in the ANSYS Fluent calculation, but the accuracy of the ANSYS Fluent calculation will otherwise be unaffected.

Important

If you choose to remove any species, be sure to also update the number of species (keyword `NUMOFSPECIES`) in the flamelet data file, to reflect the loss of any species you have removed from the file.

If a species with relatively large concentration is missing from the ANSYS Fluent thermodynamic databases, you will have to add it. Removing a high-concentration species from the flamelet file is not recommended.

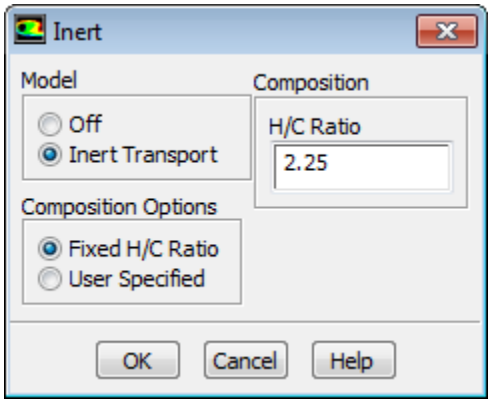
15.9. Setting Up the Inert Model

This section describes how to set up and apply the inert model. For a discussion about the theory, refer to Using the Non-Premixed Model with the Inert Model in the Theory Guide.

To enable the inert model, make sure that the non-premixed or partially premixed model is selected in the **Species Model** dialog box, or that a PDF file is read. Refer to Steps in Using the Non-Premixed Model (p. 1025) and Modeling Partially Premixed Combustion (p. 1099) to learn more about these models.

Setup → Models → Inert Edit...

Figure 15.28: The Inert Model Dialog Box



The **Inert** dialog box will be displayed (Figure 15.28: The Inert Model Dialog Box (p. 1075)). To enable this model, select **Inert Transport**. The following steps will walk you through setting up the inert model:

1. Select **Fixed H/C Ratio** as the **Composition Option** if the hydrogen to carbon ratio is known. For example, for methane (CH_4) enter 4 for **H/C Ratio**.

   Setting the H/C ratio assumes that the burned gas resulted from the complete, stoichiometric combustion of that hydrocarbon fuel with air, and the only products of the combustion are CO_2, H_2O and N_2.

2. Select **User Specified** as the **Composition Option** if you want to specify an arbitrary composition for the inert stream, as shown in Figure 15.29: The Inert Model Dialog Box (p. 1076).

   Figure 15.29: The Inert Model Dialog Box

   You can specify your composition stream by adding or removing species if your stream is composed of species other than the default species list.

   a. To add species to the **Species** list, type the chemical formula under **Inert Species** and click **Add**.

   b. Enter the **Mass Fraction** of the newly added species. Continue in this manner until all of the inert species you want to include are shown in the **Species** list.

   c. Make sure the sum of the mass fractions add up to 1. ANSYS Fluent will normalize the species mass fractions for you when you click **Normalize Species**.

   d. To remove a species from the list, type the chemical formula under **Inert Species** and click **Remove**.

   e. To print a list of all species in the thermodynamic database file (`thermo.db`) in the console window, click **List Available Species**.

15.9.1. Setting Boundary Conditions for Inert Transport

You will need to set appropriate boundary conditions at flow inlets and exits for the inert tracer mass fraction, Y_I. The tracer species mass fraction must be between zero and one, with the value of one meaning that all of the material entering the domain comes from the inert stream. The values for flow boundaries are set in the **Inert Stream** field of the inlet boundary condition dialog boxes, under the **Species** tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.9.2. Initializing the Inert Stream

The main assumption of the inert model is that the composition of the inert stream does not change with combustion. For some dilutants, this is a very reasonable assumption, however, it is not valid for rich combustion where there is fuel in the exhaust stream. For cases where there is fuel or oxidizer left in the exhaust gas, the accuracy of your results will depend upon taking the fuel or oxidizer species into account when setting initial conditions.

15.9.2.1. Inert Fraction

Initialization of the inert mass fraction Y_I is done in the same way as other variables: by entering in the appropriate value in the **Solution Initialization** task page. Another option for initialization is to patch the value of Y_I in a region of the domain. When the value of Y_I is patched in this way, ANSYS Fluent automatically recalculates the enthalpy field for the current temperature field in order to account for the change in composition.

See Patching Values in Selected Cells (p. 1593) for details about patching values of solution variables.

15.9.2.2. Inert Composition

For combustion calculations that burn a hydrocarbon fuel, ANSYS Fluent provides a straightforward way of setting the initial composition of the inert stream. The inert composition can be set by assuming a ratio of hydrogen to carbon in the following overall oxidation reaction (from Heywood [42] (p. 2889)):

$$C_aH_b+\left(a+\frac{b}{4}\right)\left(O_2+3.773N_2\right)=aCO_2+\frac{b}{2}H_2O+3.773\left(a+\frac{b}{4}\right)N_2 \tag{15.8}$$

which can be rewritten in terms of the ratio of hydrogen to carbon atoms ($y=b/a$) in the fuel as

$$CH_y+\left(1+\frac{y}{4}\right)\left(O_2+3.773N_2\right)=CO_2+\frac{y}{2}H_2O+3.773\left(1+\frac{y}{4}\right)N_2 \tag{15.9}$$

If Equation 15.9 (p. 1077) is solved for the mass fractions of CO_2, H_2O and N_2, the following relations are obtained:

$$\begin{aligned} Y_{CO_2} &= \frac{44.01}{y_{tot}} \\ Y_{H_2O} &= \frac{9.01y}{y_{tot}} \\ Y_{N_2} &= \frac{26.56192y+106.24768}{y_{tot}} \end{aligned} \tag{15.10}$$

where

$$y_{tot}=35.57192y+150.25768$$

Setting the H/C ratio assumes that the burned gas resulted from the complete, stoichiometric combustion of that hydrocarbon fuel, and the only products of the combustion are CO_2, H_2O and N_2. An arbitrary composition for the inert stream can also be specified in the interface.

15.9.3. Resetting Inert EGR

ANSYS Fluent allows burned gases to be converted to an inert gas. This has been designed with in-cylinder combustion in mind to aid the simulation of multiple cycles of such engines using the partially-premixed combustion model with exhaust gas recirculation (EGR). At the end of a combustion stroke, the premixed progress variable of the burnt gases is unity. When fresh charge, with progress variable

of zero, is mixed with the burnt trapped gases, combustion will be initiated unless these trapped gases are converted to inert.

This facility is accessed via the **Dynamic Mesh Events** dialog box, as described in Resetting Inert EGR (p. 722). There, you will need to set the crank angle at which the event occurs (usually shortly before the inlet valves open) and at the fluid zones (usually the combustion chamber) where the burnt gases are converted to inert.

When ANSYS Fluent performs an inert reset, the inert composition is calculated as the stoichiometric composition. For lean mixtures, the stoichiometric inert is mixed with oxidizer, and for rich mixtures the stoichiometric inert is mixed with fuel, so that overall stoichiometry is conserved. This entails:

- Calculating the stoichiometric mixture fraction, which is defined as the mixture where both fuel and oxidizer are completely consumed.
- Calculating the inert species mass fractions as the stoichiometric species mass fractions. Species with mole fractions less than 0.01 are discarded.
- Setting the inert mass fraction and the mixture fraction as follows:
  - Lean mixtures

$$Y_i = Y_{i,old} + \left(1.0 - Y_{i,old}\right) \cdot \tilde{c} \cdot \frac{\tilde{f}}{\tilde{f}_{sto}}$$

$$\tilde{f} = \tilde{f}_{old} \cdot \left(1.0 - \tilde{c}\right)$$

  - Rich mixtures

$$Y_i = Y_{i,old} + \left(1.0 - Y_{i,old}\right) \cdot \tilde{c} \cdot \frac{1.0 - \tilde{f}_{old}}{1.0 - \tilde{f}_{sto}}$$

$$\tilde{f} = \tilde{f}_{old} \cdot \left(1.0 - \tilde{c}\right) + \tilde{c} \cdot \frac{\tilde{f}_{old} - \tilde{f}_{sto}}{1.0 - \tilde{f}_{sto}}$$

    where Y_i is the inert mass fraction, f is the mixture fraction, c is the reaction progress, subscript *sto* denotes stoichiometric, subscript *old* denotes values before inert reset, tilde superscript denotes Favre averaging.

- Setting the reaction progress to zero.
  - For the ECFM model, flame area density is set to zero.
  - For the G-Equation model, G (the mean distance from the flame front) is set to a negative value.
- Since there will be some small errors in the species mass fractions from before the EGR reset, the temperature will change due to the change in the specific heat. By default, ANSYS Fluent adjusts the enthalpy so that temperature is unchanged after EGR reset. This may be limited by the PDF table temperature limits for the new mixture fraction, in which case the temperature after inert reset will not equal the temperature before the inert reset event.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.10. Defining Non-Premixed Boundary Conditions

For information about defining non-premixed boundary conditions, see the following sections:

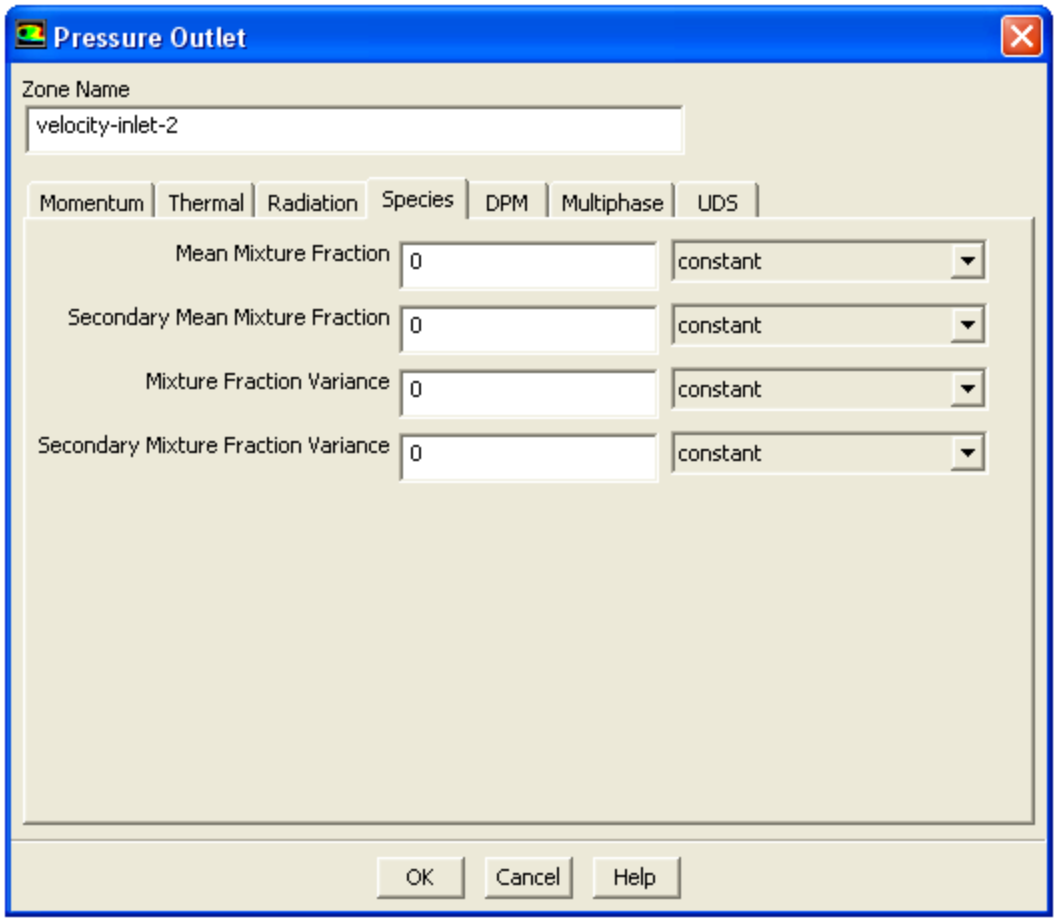
15.10.1. Input of Mixture Fraction Boundary Conditions
15.10.2. Diffusion at Inlets
15.10.3. Input of Thermal Boundary Conditions and Fuel Inlet Velocities

15.10.1. Input of Mixture Fraction Boundary Conditions

When the non-premixed combustion model is used, flow boundary conditions at inlets and exits (that is, velocity or pressure, turbulence intensity) are defined in the usual way. Species mass fractions at inlets are not required. Instead, you define values for the mean mixture fraction, $\overline{f}$, and the mixture fraction variance, $\overline{f'^2}$, at inlet boundaries. (For problems that include a secondary stream, you will define boundary conditions for the mean secondary partial fraction and its variance as well as the mean fuel mixture fraction and its variance.) These inputs provide boundary conditions for the conservation equations you will solve for these quantities. The inlet values are supplied in the boundary conditions task page, under the available tabs, for the selected inlet boundary (for example, Figure 15.30: The Velocity Inlet Dialog Box Showing Mixture Fraction Boundary Conditions (p. 1079)).

Setup → Boundary Conditions

Figure 15.30: The Velocity Inlet Dialog Box Showing Mixture Fraction Boundary Conditions



Click the **Species** tab and specify the **Mean Mixture Fraction** and **Mixture Fraction Variance** (and the **Secondary Mean Mixture Fraction** and **Secondary Mixture Fraction Variance**, if you are using two mixture fractions). In general, the inlet value of the mean fractions will be 1.0 or 0.0 at flow inlets: the mean fuel mixture fraction will be 1.0 at fuel stream inlets and 0.0 at oxidizer or secondary stream inlets; the mean secondary mixture fraction will be 1.0 at secondary stream inlets and 0.0 at fuel or oxidizer inlets. The fuel or secondary mixture fraction will lie between 0.0 and 1.0 only if you are modeling flue gas recycle, as illustrated in Figure 8.15: Using the Non-Premixed Model with Flue Gas Recycle and discussed in Definition of the Mixture Fraction in the Theory Guide. The fuel or secondary mixture fraction variance can usually be taken as zero at inlet boundaries.

15.10.2. Diffusion at Inlets

In some cases, you may want to include the diffusive transport of mixture fraction through the inlets of your domain. You can do this by enabling inlet mixture-fraction diffusion. By default, ANSYS Fluent excludes the diffusion flux of mixture fraction at inlets. To enable inlet diffusion, use either the

```
define/models/ species/inlet-diffusion?
```

text command, or the **Species Model** dialog box (Figure 15.1: Defining Equilibrium Chemistry (p. 1027))

Setup → **Models** → **Species** **Edit...**

and enable the **Inlet Diffusion** option.

15.10.3. Input of Thermal Boundary Conditions and Fuel Inlet Velocities

If your model is non-adiabatic, you should specify the **Temperature** at the flow inlets. Recall that the inlet temperatures were requested during the table construction in the **Chemistry** tab of the **Species Model** dialog box, and were used in the construction of the look-up tables. The inlet temperatures for each fuel, oxidizer, and secondary inlet in your non-adiabatic model should be defined, in addition, as boundary conditions in ANSYS Fluent. It is acceptable for the inlet temperature boundary conditions to differ slightly from those you input for the look-up table calculations. If the inlet temperatures differ significantly from those in the **Chemistry** tab, however, your look-up tables may provide inaccurate interpolation. This is because the discrete points in the look-up tables were clustered around a finite range of the temperatures defined in the **Chemistry** tab, and your input in the ANSYS Fluent inlet boundary condition may fall outside this range.

Wall thermal boundary conditions should also be defined for non-adiabatic non-premixed combustion calculations. You can use any of the standard conditions available in ANSYS Fluent, including specified wall temperature, heat flux, external heat transfer coefficient, or external radiation. If radiation is to be included within the domain, the wall emissivity should be defined as well. See Thermal Boundary Conditions at Walls (p. 370) for details about thermal boundary conditions at walls.

15.11. Defining Non-Premixed Physical Properties

When you use the non-premixed combustion model, the material used for all fluid zones is automatically set to **pdf-mixture**. This material is a special case of the mixture material concept discussed in Mixture Materials (p. 959). The constituent species of this mixture are the species that were calculated in the PDF look-up table creation; you cannot change them directly. When the non-premixed model is used, heat capacities, molecular weights, and enthalpies of formation for each species considered are extracted from the chemical database, so you will not modify any properties for the constituent species in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

PDF mixture. For the PDF mixture itself, the mean density and mean specific heat are determined from the look-up tables.

The physical property inputs for a non-premixed combustion problem are therefore only the transport properties (viscosity, thermal conductivity, and so on) for the PDF mixture. To set these in the Create/Edit Materials Dialog Box (p. 2302), choose **mixture** as the **Material Type**, **pdf-mixture** (the default, and only choice) in the **Mixture Materials** list, and set the desired values for the transport properties.

Setup → **Materials**

See Physical Properties (p. 459) for details about setting physical properties. The transport properties in a non-premixed combustion problem can be defined as functions of temperature, if desired, but not as functions of composition. In practice, since turbulence effects will dominate, it will be of little benefit to include even the temperature dependence of the laminar transport properties.

If you are modeling radiation heat transfer, you will also enter radiation properties, as described in Radiation Properties (p. 515). Composition-dependent absorption coefficients (using the WSGGM) are allowed.

The non-premixed model can also be used with real gas models in ANSYS Fluent, if the **Compressibility Effects** option is enabled in the **Species Model** dialog box. In this case, the density method is based on one of the four real gas models, discussed in Equation of State (p. 537) and Using the Cubic Equation of State Real Gas Models (p. 542).

15.12. Solution Strategies for Non-Premixed Modeling

The non-premixed model setup and solution procedure in ANSYS Fluent differs slightly for single- and two-mixture-fraction problems. Below, an overview of each approach is provided. Note that your ANSYS Fluent case file must always meet the restrictions listed for the non-premixed modeling approach in Restrictions on the Mixture Fraction Approach in the Theory Guide. In this section, details are provided regarding the problem definition and calculation procedures you follow in ANSYS Fluent.

For additional information, see the following sections:

15.12.1. Single-Mixture-Fraction Approach
15.12.2. Two-Mixture-Fraction Approach
15.12.3. Starting a Non-Premixed Calculation From a Previous Case File
15.12.4. Solving the Flow Problem

15.12.1. Single-Mixture-Fraction Approach

For a single-mixture-fraction system, when you have completed the calculation of the PDF look-up tables, you are ready to begin your reacting flow simulation. In ANSYS Fluent, you will solve the flow field and predict the spatial distribution of $\overline{f}$ and $\overline{f'^2}$ (and $\overline{H}$ if the system is non-adiabatic or $\overline{\chi}$ if the system is based on laminar flamelets). ANSYS Fluent will obtain the corresponding values of temperature and individual chemical species mass fractions from the look-up tables.

15.12.2. Two-Mixture-Fraction Approach

When a secondary stream is included, ANSYS Fluent will solve transport equations for the mean secondary partial fraction (p_{sec}) and its variance in addition to the mean fuel mixture fraction and its variance. ANSYS Fluent will then look up the instantaneous values for temperature, density, and individual chemical species in the look-up tables, compute the PDFs for the fuel and secondary streams, and calculate the mean values for temperature, density, and species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that in order to avoid both inaccuracies and unnecessarily slow calculation times, it is important for you to view your temperature and species tables in ANSYS Fluent to ensure that they are adequately but not excessively resolved.

15.12.3. Starting a Non-Premixed Calculation From a Previous Case File

You can read a previously defined ANSYS Fluent case file as a starting point for your non-premixed combustion modeling. If this case file contains inputs that are incompatible with the current non-premixed combustion model, ANSYS Fluent will alert you when the non-premixed model is turned on and it will turn off those incompatible models. For example, if the case file includes species that differ from those included in the PDF file created by ANSYS Fluent, these species will be disabled. If the case file contains property descriptions that conflict with the property data in the chemical database, these property inputs will be ignored.

Important

PDF files created by prePDF 2 or older are not supported by this version of ANSYS Fluent. The files generated by PrePDF version 3 or newer, are fully compatible.

In the **Species Model** dialog box, select **Non-Premixed Combustion** under the **Model** heading. When you click **OK** in the **Species Model** dialog box, The Select File Dialog Box (p. 19) will immediately appear, prompting you for the name of the PDF file containing the look-up tables created in a previous ANSYS Fluent session. (The PDF file is the file you saved using the **File/Write/PDF...** ribbon tab item after computing the look-up tables.) ANSYS Fluent will indicate that it has successfully read the specified PDF file:

```
Reading "/home/mydirectory/adiabatic.pdf"...
read 5 species (binary c, adiabatic fluent)
pdf file successfully read.
Done.
```

After you read in the PDF file, ANSYS Fluent will inform you that some material properties have changed. You can accept this information; you will be updating properties later on.

You can read in an altered PDF file at any time by using the **File/Read/PDF...** ribbon tab item.

Important

Recall that the non-premixed combustion model is available only when you used the pressure-based solver; it cannot be used with the density-based solvers. Also, the non-premixed combustion model is available only when turbulence modeling is active.

If you are modeling a non-adiabatic system and you want to include the effects of compressibility, re-open the **Species Model** dialog box and turn on **Compressibility Effects** under **PDF Options**. This option tells ANSYS Fluent to update the density according to Equation 15.1 (p. 1033). When the non-premixed combustion model is active, you can enable compressibility effects only in the **Species Model** dialog box. For other models, you will specify compressible flow (**ideal-gas**, **boussinesq**, and so on) in the **Create/Edit Materials** dialog box. See Specifying the Operating Pressure for the System (p. 1033) and Tuning the PDF Parameters for Two-Mixture-Fraction Calculations (p. 1084) for more information about compressibility effects.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.12.3.1. Retrieving the PDF File During Case File Reads

The PDF filename is specified to ANSYS Fluent only once. Thereafter, the filename is stored in your ANSYS Fluent case file and the PDF file will be automatically read into ANSYS Fluent whenever the case file is read. ANSYS Fluent will remind you that it is reading the PDF file after it finishes reading the rest of the case file by reporting its progress in the text (console) window.

Note that the PDF filename stored in your case file may not contain the full name of the directory in which the PDF file exists. The full directory name will be stored in the case file only if you initially read the PDF file through the GUI (or if you typed in the directory name along with the filename when using the text interface). In the event that the full directory name is absent, the automatic reading of the PDF file may fail (since ANSYS Fluent does not know which directory to look in for the file), and you will need to manually specify the PDF file. The safest approaches are to use the GUI when you first read the PDF file or to supply the full directory name when using the text interface.

15.12.4. Solving the Flow Problem

The next step in the non-premixed combustion modeling process in ANSYS Fluent is the solution of the mixture fraction and flow equations. First, initialize the flow. By default, the mixture fraction and its variance have initial values of zero, which is the recommended value; you should generally not set nonzero initial values for these variables. See Initializing the Solution (p. 1591) for details about solution initialization.

Solution → **Initialization**

Next, begin calculations in the usual manner.

Solution → **Run Calculation**

During the calculation process, ANSYS Fluent reports residuals for the mixture fraction and its variance in the `fmean` and `fvar` columns of the residual report:

```
iter       cont       x-vel       y-vel          k     epsilon       fmean       fvar
  28    1.57e-3     4.92e-4     4.80e-4    2.68e-2     2.59e-3     9.09e-1    1.17e+0
  29    1.42e-3     4.43e-4     4.23e-4    2.48e-2     2.30e-3     8.89e-1    1.15e+0
  30    1.28e-3     3.98e-4     3.75e-4    2.29e-2     2.04e-3     8.88e-1    1.14e+0
```

(For two-mixture-fraction calculations, columns for `psec` and `pvar` will also appear.)

15.12.4.1. Under-Relaxation Factors for PDF Equations

The transport equations for the mean mixture fraction and mixture fraction variance are quite stable and high, under-relaxation can be used when solving them. By default, an under-relaxation factor of 1 is used for the mean mixture fraction (and secondary partial fraction) and 0.9 for the mixture fraction variance (and secondary partial fraction variance). If the residuals for these equations are increasing, you should consider decreasing these under-relaxation factors, as discussed in Setting Under-Relaxation Factors (p. 1564).

15.12.4.2. Density Under-Relaxation

One of the main reasons a combustion calculation can have difficulty converging is that large changes in temperature cause large changes in density, which can, in turn, cause instabilities in the flow solution. ANSYS Fluent allows you to under-relax the change in density to alleviate this difficulty. The default

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

value for density under-relaxation is 1, but if you encounter convergence trouble you may want to reduce this to a value between 0.5 and 1 (in the **Solution Controls** task page).

Note that if you are using a real-gas model the solution might converge at a slower rate than when running ideal-gas flow. To improve the convergence performance of your analysis, you need to reduce the underrelaxation for density to values as low as 0.1.

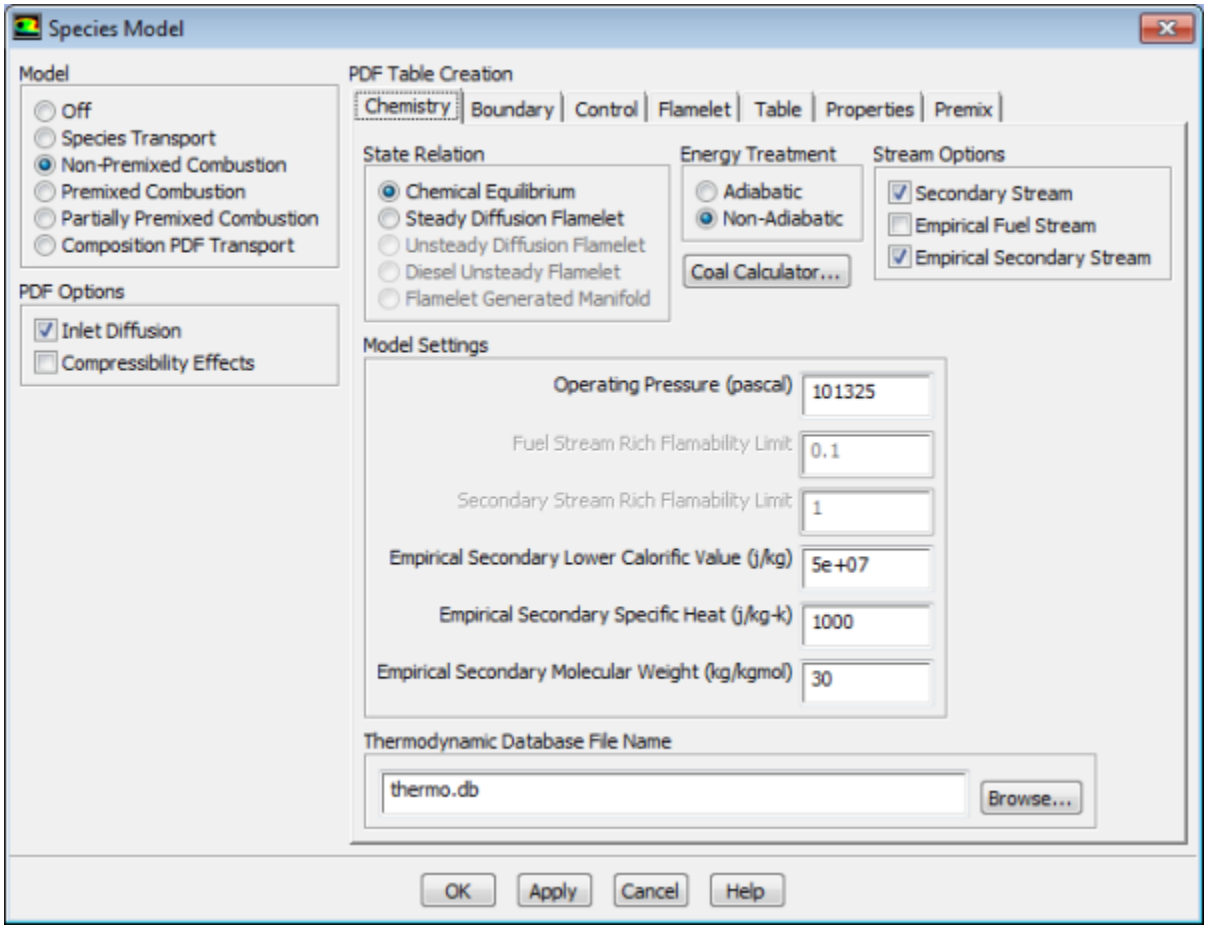
15.12.4.3. Tuning the PDF Parameters for Two-Mixture-Fraction Calculations

For cases that include a secondary stream, the PDF integrations are performed inside ANSYS Fluent.

The parameters for these integrations are defined in the Species Model Dialog Box (p. 2216) (Figure 15.31: The Species Model Dialog Box for a Two-Mixture-Fraction Calculation (p. 1084)).

Setup → Models → Species **Edit...**

Figure 15.31: The Species Model Dialog Box for a Two-Mixture-Fraction Calculation



The parameters are as follows:

Compressibility Effects

(non-adiabatic systems only) tells ANSYS Fluent to update the density, temperature, species mass fraction, and enthalpy from the PDF tables to account for the varying pressure of the system.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

15.13. Postprocessing the Non-Premixed Model Results

The final step in the non-premixed combustion modeling process is the postprocessing of species concentrations and temperature data from the mixture fraction and flow-field solution data. The following variables are of particular interest:

- **Mean Mixture Fraction** (in the **Pdf...** category)
- **Secondary Mean Mixture Fraction** (in the **Pdf...** category)
- **Mixture Fraction Variance** (in the **Pdf...** category)
- **Secondary Mixture Fraction Variance** (in the **Pdf...** category)
- **Fvar Prod** (in the **Pdf...** category, which is the production term in the mixture fraction variance transport equation)
- **Fvar2 Prod** (in the **Pdf...** category)
- **Scalar Dissipation** (in the **Pdf...** category)
- **PDF Table Adiabatic Enthalpy** (in the **Pdf...** category)
- **PDF Table Heat Loss/Gain** (in the **Pdf...** category)
- **Mass fraction of (species-n)** (in the **Species...** category)
- **Mole fraction of (species-n)** (in the **Species...** category)
- **Molar Concentration of (species-n)** (in the **Species...** category)
- **RMS (species-n) Mass Fraction** (in the **Species...** category)
- **Static Temperature** (in the **Temperature...** category)
- **RMS Temperature** (in the **Temperature...** category)
- **Enthalpy** (in the **Temperature...** category)
- **Probability** (in the **Unsteady Flamelet...** category)
- **Mean Temperature** (in the **Unsteady Flamelet...** category)
- **Mean Mass Fraction of (species-n)** (in the **Unsteady Flamelet...** category)

Important

For the unsteady diffusion flamelet model, mean species mass fractions are displayed for the first fifty species in the flamelet kinetic mechanism.

These quantities can be selected for display in the indicated category of the variable-selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1931) for their definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In all cases, the species concentrations are derived from the mixture fraction/variance field using the look-up tables. Note that temperature and enthalpy can be postprocessed even when your ANSYS Fluent model is an adiabatic non-premixed combustion simulation in which you have not solved the energy equation. In both the adiabatic and non-adiabatic cases, the temperature is derived from the look-up table.

Figure 15.32: Predicted Contours of Mixture Fraction in a Methane Diffusion Flame (p. 1086) and Figure 15.33: Predicted Contours of CO2 Mass Fraction Using the Non-Premixed Combustion Model (p. 1086) illustrate typical results for a methane diffusion flame modeled using the non-premixed approach.

Figure 15.32: Predicted Contours of Mixture Fraction in a Methane Diffusion Flame

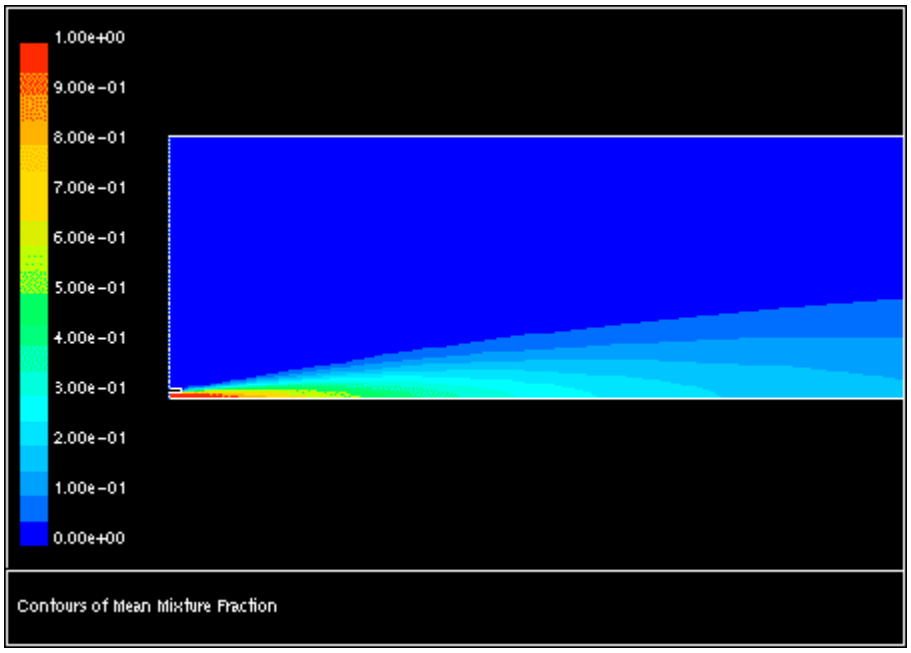


Figure 15.33: Predicted Contours of CO2 Mass Fraction Using the Non-Premixed Combustion Model

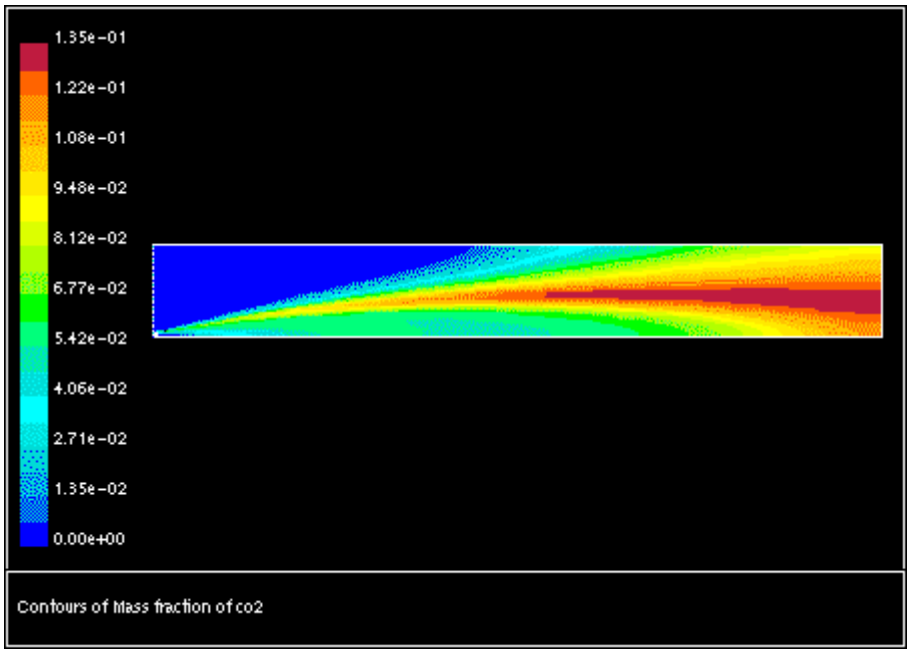

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For additional information, see the following section:
15.13.1. Postprocessing for Inert Calculations

15.13.1. Postprocessing for Inert Calculations

ANSYS Fluent provides several additional reporting options for post-processing calculations with the inert model. You can generate graphical plots or alphanumeric reports of the same items that are available with the non-premixed or partially premixed models, and in addition the following variables are available:

- **Inert Mass Fraction**
- **Inert Specific Heat**
- **Inert Density**
- **Inert Enthalpy**
- **Pdf Enthalpy**
- **Pdf Fmean**
- **Pdf Fvar**
- **Mass Fraction of Inert** Y_i

where the mass fraction of the i^{th} inert species, Y_i, is calculated as

$$Y_i = Y_I Y_i^I$$

where Y_I is the inert tracer and Y_i^I is the mass fraction of the i^{th} inert species defined in the **Inert** dialog box.

Note these variables appear in the **Inert...** category.

Chapter 16: Modeling Premixed Combustion

ANSYS Fluent has several models to simulate premixed turbulent combustion. For theoretical background on this model, see Premixed Combustion in the Theory Guide. Information about using this model is provided in the following sections:

16.1. Overview and Limitations
16.2. Using the Premixed Combustion Model
16.3. Setting Up the C-Equation and G-Equation Models
16.4. Setting Up the Extended Coherent Flame Model
16.5. Postprocessing for Premixed Combustion Calculations

16.1. Overview and Limitations

In premixed combustion, fuel and oxidizer are mixed at the molecular level prior to ignition. Combustion occurs as a flame front propagating into the unburnt reactants. Examples of premixed combustion include aspirated internal combustion engines, lean-premixed gas turbine combustors, and gas-leak explosions.

Premixed combustion is much more difficult to model than non-premixed combustion. The reason for this is that premixed combustion usually occurs as a thin, propagating flame that is stretched and contorted by turbulence. For subsonic flows, the overall rate of propagation of the flame is determined by both the laminar flame speed and the turbulent eddies. The laminar flame speed is determined by the rate that species and heat diffuse upstream into the reactants and burn. To capture the laminar flame speed, the internal flame structure would need to be resolved, as well as the detailed chemical kinetics and molecular diffusion processes. Because practical laminar flame thicknesses are of the order of millimeters or smaller, resolution requirements are usually unaffordable.

The effect of turbulence is to wrinkle and stretch the propagating laminar flame sheet, increasing the sheet area and, in turn, the effective flame speed. The large turbulent eddies tend to wrinkle and corrugate the flame sheet, while the small turbulent eddies, if they are smaller than the laminar flame thickness, may penetrate the flame sheet and modify the laminar flame structure.

Non-premixed combustion, in comparison, can be greatly simplified to a mixing problem (see the mixture fraction approach in Introduction in the Theory Guide). The essence of premixed combustion modeling lies in capturing the turbulent flame speed, which is influenced by both the laminar flame speed and the turbulence.

In premixed flames, the fuel and oxidizer are intimately mixed before they enter the combustion device. Reaction then takes place in a combustion zone that separates unburnt reactants and burnt combustion products. Partially premixed flames exhibit the properties of both premixed and diffusion flames. They occur when an additional oxidizer or fuel stream enters a premixed system, or when a diffusion flame becomes lifted off the burner so that some premixing takes place prior to combustion.

Premixed and partially premixed flames can be modeled using ANSYS Fluent's finite-rate/eddy-dissipation formulation (see Modeling Species Transport and Finite-Rate Chemistry (p. 957)). If finite-rate chemical kinetic effects are important, the Laminar Finite-Rate model (see Direct Use of Finite-Rate Kinetics (no TCI) in the Theory Guide), the EDC model (see The Eddy-Dissipation-Concept (EDC) Model in the Theory Guide) or the composition PDF transport model (see Modeling a Composition PDF Transport Prob-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

lem (p. 1113)) can be used. For information about ANSYS Fluent's partially premixed combustion model, see Modeling Partially Premixed Combustion (p. 1099). If the flame is perfectly premixed, so only one stream at one equivalence ratio enters the combustor, it is possible to use the premixed combustion model, as described in this chapter.

16.1.1. Limitations of the Premixed Combustion Model

The following limitations apply to the premixed combustion model:

- You must use the pressure-based solver. The premixed combustion model is not available with the density-based solver.
- The premixed combustion model is valid only for turbulent, subsonic flows. These types of flames are called deflagrations. Explosions, also called detonations, where the combustible mixture is ignited by the heat behind a shock wave, can be modeled with the finite-rate model using the density-based solver. See Modeling Species Transport and Finite-Rate Chemistry (p. 957) for information about the finite-rate model.
- The premixed combustion model cannot be used in conjunction with the pollutant (that is, soot and NOx) models. However, a perfectly premixed system can be modeled with the partially premixed model (see Modeling Partially Premixed Combustion (p. 1099)), which can be used with the pollutant models.
- You cannot use the premixed combustion model to simulate reacting discrete-phase particles, because these would result in a partially premixed system. Only inert particles can be used with the premixed combustion model.
- The G-Equation model can be used only with the unsteady solver because it tracks the flame front in time. However, RANS solutions, which tend to a steady-state, can be modeled by evolving them in time until the solution is stationary.

16.2. Using the Premixed Combustion Model

The procedure for setting up and solving a premixed combustion model is outlined below, and then described in detail. Remember that only the steps that are pertinent to premixed combustion modeling are shown here. For information about inputs related to other models that you are using in conjunction with the premixed combustion model, see the appropriate sections for those models.

1. Enable the premixed turbulent combustion model and set the related parameters.

   Note

   Make sure a turbulence model (other than the Spalart-Allmaras model) is selected before selecting a combustion model.

   Setup → **Models** → **Species** **Edit...**

2. Define the physical properties for the unburnt and burnt material in the domain.

   Setup → **Materials** → **Create/Edit...**

3. Set the value of the progress variable c at flow inlets and exits.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → **Boundary Conditions**

4. Initialize and patch the value of the progress variable.

   Solution → **Initialization** → **Patch...**

5. Solve the problem and perform postprocessing.

Important

If you are interested in computing the concentrations of individual species in the domain, you can use the partially premixed model described in Modeling Partially Premixed Combustion (p. 1099). Alternatively, compositions of the unburnt and burnt mixtures can be obtained from external analyses using equilibrium or kinetic calculations.

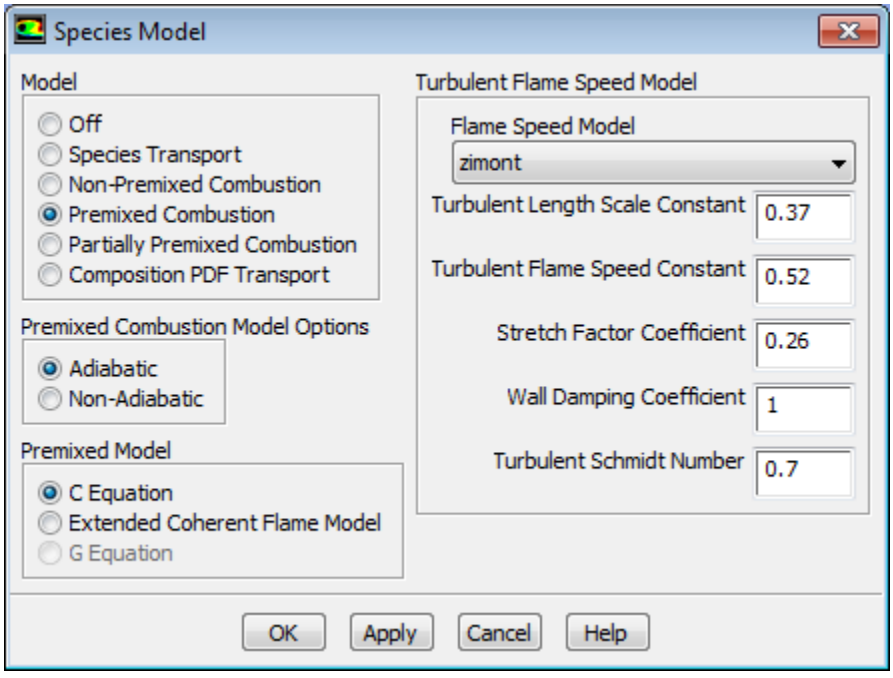
For additional information, see the following sections:
16.2.1. Enabling the Premixed Combustion Model
16.2.2. Choosing an Adiabatic or Non-Adiabatic Model

16.2.1. Enabling the Premixed Combustion Model

To enable the premixed combustion model, select **Premixed Combustion** under **Model** in the Species Model Dialog Box (p. 2216) (Figure 16.1: The Species Model Dialog Box for Premixed Combustion (p. 1091)).

Setup → **Models** → **Species** **Edit...**

Figure 16.1: The Species Model Dialog Box for Premixed Combustion



When you enable **Premixed Combustion**, the dialog box expands to show the relevant inputs.

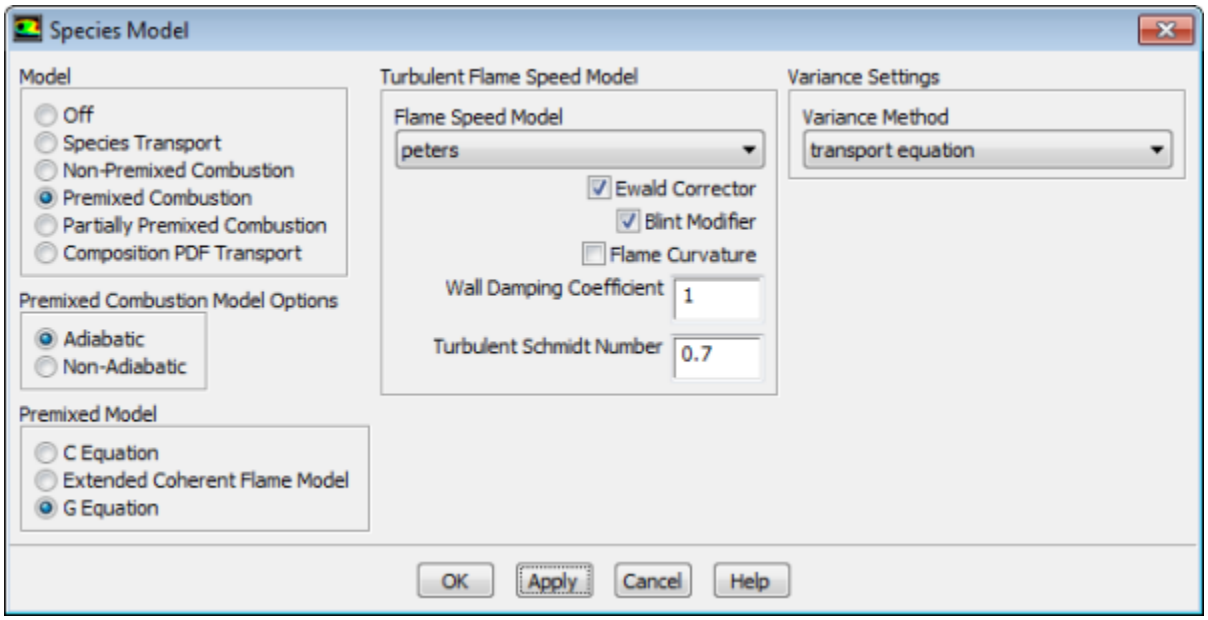
16.2.2. Choosing an Adiabatic or Non-Adiabatic Model

Under **Premixed Combustion Model Options** in the Species Model Dialog Box (p. 2216), choose either **Adiabatic** (the default) or **Non-Adiabatic**. This choice affects only the calculation method used to determine the temperature (either Equation 9.65 or Equation 9.66 in the Theory Guide).

16.3. Setting Up the C-Equation and G-Equation Models

When **C Equation** or **G Equation** is selected as the **Premixed Model**, you can then choose to use the **zimont** or **peters Flame Speed Model** (described in Turbulent Flame Speed Models). You can also modify a number of model constants, as described in Modifying the Constants for the Zimont Flame Speed Model (p. 1092) and Modifying the Constants for the Peters Flame Speed Model (p. 1093).

Figure 16.2: The Species Model Dialog Box for the G-Equation Model



For a non-adiabatic premixed combustion model, note that the value you specify for the **Turbulent Schmidt Number** will also be used as the Prandtl number for energy. (The **Energy Prandtl Number** will therefore not appear in the **Viscous Model** dialog box for non-adiabatic premixed combustion models.) These parameters control the level of diffusion for the progress variable and for energy. The progress variable is closely related to energy (because the flame progress results in heat release), so it is important that the transport equations use the same level of diffusion.

For additional information, see the following sections:

16.3.1. Modifying the Constants for the Zimont Flame Speed Model
16.3.2. Modifying the Constants for the Peters Flame Speed Model
16.3.3. Additional Options for the G-Equation Model
16.3.4. Defining Physical Properties for the Unburnt Mixture
16.3.5. Setting Boundary Conditions for the Progress Variable
16.3.6. Initializing the Progress Variable

16.3.1. Modifying the Constants for the Zimont Flame Speed Model

In general, you will not need to modify the constants used in the equations presented in C-Equation Model Theory in the Theory Guide. The default values are suitable for a wide range of premixed flames.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can set the **Turbulent Length Scale Constant** (C_D in Equation 9.11), **Turbulent Flame Speed Constant** (A in Equation 9.9), the **Stretch Factor Coefficient** (μ_{str} in Equation 9.16), the **Turbulent Schmidt Number** (Sc_t in Equation 9.1), and the **Wall Damping Coefficient** (α_w in Equation 9.19).

16.3.2. Modifying the Constants for the Peters Flame Speed Model

The Peters turbulent flame speed model constants, as described in Peters Flame Speed Model in the Theory Guide, are not available in the GUI because they are generally suitable for a wide range of premixed flames. They can, however, be accessed from the TUI.

The **Ewald Corrector** is enabled by default and described in Peters Flame Speed Model. The **Turbulent Schmidt Number** (Sc_t in Equation 9.1), and the **Wall Damping Coefficient** (α_w in Equation 9.19) are the same as those described for the Zimont model.

16.3.3. Additional Options for the G-Equation Model

When the G-Equation model is enabled, the **G Equation Settings** group box appears. You can select either the **transport equation** or **algebraic** option for the calculation of the flame distance variance. Consult Peters Flame Speed Model in the Theory Guide for the variance transport and algebraic equation expressions (Equation 9.6 and Equation 9.7). It is recommended that you use the **transport equation** option for RANS and the **algebraic** option for LES.

When **Flame Curvature Source** is enabled, the curvature source term in the G-Equation, which is the last term in Equation 9.4, is included. By default, this term is excluded.

16.3.4. Defining Physical Properties for the Unburnt Mixture

The fluid material in your domain should be assigned the properties of the unburnt mixture, including the thermal diffusivity (α in Equation 9.9 in the Theory Guide). α is defined as $k/\rho c_p$, and values at standard conditions can be found in combustion handbooks (for example, [55] (p. 2890)).

For both adiabatic and non-adiabatic combustion models, you will need to specify the **Laminar Flame Speed** (U_l in Equation 9.9 in the Theory Guide) as a material property, in the **Create/Edit Materials** dialog box. ANSYS Fluent will automatically select the **prepdf-polynomial** function for **Laminar Flame Speed**, indicating that the piecewise-linear polynomial function from the PDF look-up table will be used to compute the laminar flame speed for the partially-premixed model. You may also choose to enter a **constant** value, use a **user-defined** function, or apply the **metghalchi-keck-law** instead of a piecewise-linear polynomial function. See Laminar Flame Speed in the Theory Guide and Defining Physical Properties for the Unburnt Mixture (p. 1093) for information about setting the other properties for the unburnt material.

When using the Zimont turbulent flame speed model, if you want to include the flame stretch effect in your model, you will also need to specify a lower value than the default **Critical Rate of Strain** (g_{cr} in Equation 9.17 in the Theory Guide). As discussed in Flame Stretch Effect in the Theory Guide, g_{cr} is set to a very high value ($1\times10^8 s^{-1}$) by default, so no flame stretching occurs. To include flame stretching effects, you will need to adjust the **Critical Rate of Strain** based on experimental data for the burner. Because the flame stretching and flame extinction can influence the turbulent flame speed (as discussed in Flame Stretch Effect in the Theory Guide), a realistic value for the **Critical Rate of Strain** is required for accurate predictions. Typical values for CH_4 lean premixed combustion range from 3000 to 8000 s^{-1} [131] (p. 2894). Note that you can specify constant values or user-defined functions to define the

Laminar Flame Speed and **Critical Rate of Strain**. See the Fluent Customization Manual for details about user-defined functions.

For adiabatic models, you will also specify the **Adiabatic Burnt Temperature** (T_{ad} in Equation 9.65 in the Theory Guide), which is the temperature of the burnt products under adiabatic conditions. This temperature will be used to determine the linear variation of temperature in an adiabatic premixed combustion calculation. You can specify a constant value or use a user-defined function.

For non-adiabatic models, you will instead specify the **Heat of Combustion** per unit mass of fuel and the **Unburnt Fuel Mass Fraction** (H_{comb} and Y_{fuel} in Equation 9.67 in the Theory Guide). ANSYS Fluent will use these values to compute the heat losses or gains due to combustion, and include these losses/gains in the energy equation that it uses to calculate temperature. The **Heat of Combustion** can be specified only as a constant value, but you can specify a constant value or use a user-defined function for the **Unburnt Fuel Mass Fraction**.

To specify the density for a premixed combustion model, choose **premixed-combustion** in the **Density** drop-down list and set the **Adiabatic Unburnt Density** and **Adiabatic Unburnt Temperature** (T_u and ρ_u in Equation 9.68 in the Theory Guide). For adiabatic premixed models, your input for **Adiabatic Unburnt Temperature** (T_u) will also be used in Equation 9.65 in the Theory Guide to calculate the temperature.

The other properties specified for the unburnt mixture are viscosity, specific heat, thermal conductivity, and any other properties related to other models that are being used in conjunction with the premixed combustion model.

16.3.5. Setting Boundary Conditions for the Progress Variable

For premixed combustion models, you will need to set an additional boundary condition at flow inlets and exits: the progress variable, c. Valid inputs for the **Progress Variable** are as follows:

- $c=0$: unburnt mixture
- $c=1$: burnt mixture

16.3.6. Initializing the Progress Variable

Often, it is sufficient to initialize the progress variable c to 1 (burnt) everywhere and allow the unburnt ($c=0$) mixture entering the domain from the inlets to blow the flame back to the stabilizer. A better initialization is to patch an initial value of 0 (unburnt) upstream of the flame holder and a value of 1 (burnt) in the downstream region (after initializing the flow field in the **Solution Initialization** task page).

Solution → **Initialization** → **Patch...**

See Patching Values in Selected Cells (p. 1593) for details about patching values of solution variables.

16.4. Setting Up the Extended Coherent Flame Model

The Extended Coherent Flame Model (ECFM) solves a transport equation for the flame surface area density, denoted Σ, in addition to the reaction progress variable. Details about setting up the reaction progress variable boundary and initial conditions, and material properties, can be found in Setting Up the C-Equation and G-Equation Models (p. 1092). To use the ECFM, select **Extended Coherent Flame**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Model as the **Premixed Model**. A list of **Extended Coherent Flame Model Constants** will appear in the **Species Model** dialog box.

For additional information, see the following sections:
16.4.1. Modifying the ECFM Model Variant
16.4.2. Modifying the Constants for the ECFM Flame Speed Closure
16.4.3. Setting Boundary Conditions for the ECFM Transport
16.4.4. Initializing the Flame Area Density

16.4.1. Modifying the ECFM Model Variant

The source terms for Equation 9.27 in the Theory Guide are determined by which ECFM model variant is used. There are four ECFM model variants available. The default Veynante scheme is the recommended scheme, because it provides the best accuracy in most situations. If you want access to a different model variant, you must use the following text command:

`define` → `models` → `species` → `set-premixed-combustion`

You can then revise the model constants as necessary. See Closure for ECFM Source Terms in the Theory Guide for further details. If you are using LES turbulence modeling, see LES and ECFM as well.

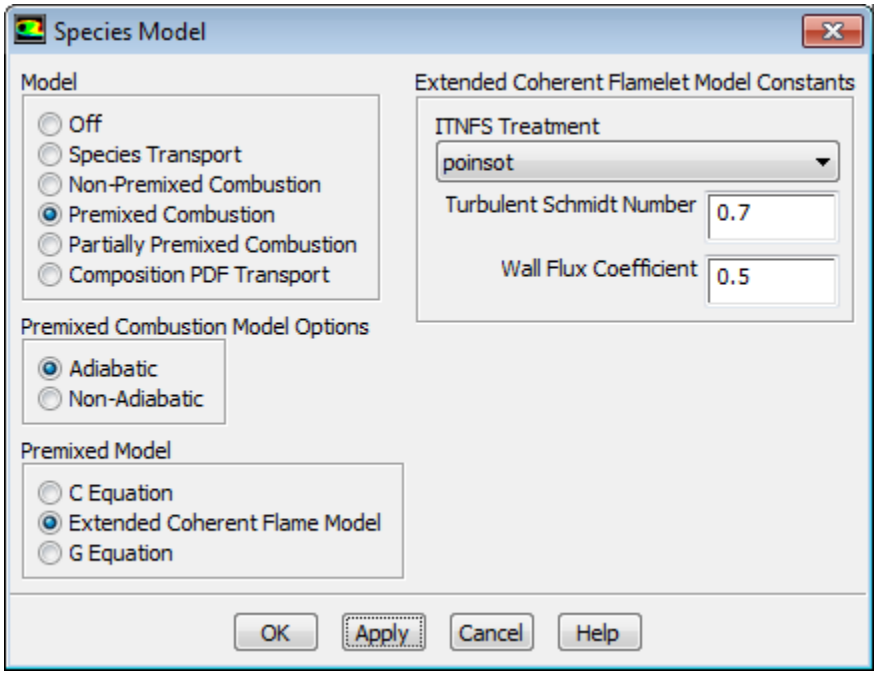
16.4.2. Modifying the Constants for the ECFM Flame Speed Closure

In the **Extended Coherent Flame Model Constants** group box of the **Species Model** dialog box, select the **ITNFS Treatment**. You have a choice of **constant-delta**, **meneveau**, **blint**, **poinsot**, or **constant**. The various ITNFS treatments are described in detail in Closure for ECFM Source Terms in the Theory Guide.

The treatment you select will determine which constants you can set. In all cases, you need to define the **Turbulent Schmidt Number** (Sc_t) and the **Wall Flux Coefficient**. If you selected the **constant-delta** treatment, you can set the **ITNFS Flame Thickness** (δ_l^0 in Equation 9.31 in the Theory Guide). If you selected the **constant** treatment, you can set the **ITNFS Value** (Γ_K in Equation 9.29 in the Theory Guide). Note that, in general, you will not need to modify the constants available in the **Extended Coherent Flame Model Constants** group box because the default values are suitable for a wide range of premixed flames.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 16.3: The Species Model Dialog Box for ECFM



16.4.3. Setting Boundary Conditions for the ECFM Transport

For the ECFM transport equation option for the premixed combustion models, you will need to set an additional boundary condition at flow inlets and exits: the flame area density, Σ. Valid inputs for the **Flame Area Density** are as follows:

- $\Sigma = 0$: no flame area (unburned)
- $\Sigma > 0$: burning with nonzero flame area

16.4.4. Initializing the Flame Area Density

Often, it is sufficient to initialize the flame area density Σ to 1 (laminar flame speed) everywhere and allow the unburnt mixture entering the domain from the inlets to develop. Another option for initialization is to patch an initial value of 0 (not burning) upstream of the flame holder and a value of 10 or higher (burning) in the downstream region (after initializing the flow field in the region).

See Patching Values in Selected Cells (p. 1593) for details about patching values of solution variables.

16.5. Postprocessing for Premixed Combustion Calculations

ANSYS Fluent provides several additional reporting options for premixed combustion calculations. You can generate graphical plots or alphanumeric reports of the following items:

- **Progress Variable**
- **Damkohler Number**
- **Stretch Factor**
- **Turbulent Flame Speed**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Static Temperature**
- **Product Formation Rate**
- **Laminar Flame Speed**
- **Critical Strain Rate**
- **Unburnt Fuel Mass Fraction**
- **Adiabatic Flame Temperature**

These variables are contained in the **Premixed Combustion...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. See Field Function Definitions (p. 1931) for a complete list of flow variables, field functions, and their definitions. Displaying Graphics (p. 1747) and Reporting Alphanumeric Data (p. 1885) explain how to generate graphics displays and reports of data.

Note that **Static Temperature** and **Adiabatic Flame Temperature** will appear in the **Premixed Combustion...** category only for adiabatic premixed combustion calculations; for non-adiabatic calculations, **Static Temperature** will appear in the **Temperature...** category. **Unburnt Fuel Mass Fraction** will appear only for non-adiabatic models.

ANSYS Fluent also provides several additional reporting options for premixed combustion calculations with the ECFM model for flame speed closure. You can generate graphical plots or alphanumeric reports of the same items that are available with the premixed mode, and in addition:

- **Progress Variable Curvature**
- **Flame Area Density**
- **Net Flame Area Production**
- **Flame Area Production P1**
- **Flame Area Production P2**
- **Flame Area Production P3**
- **Flame Area Production P4**
- **Intermittent Turb Net Flame Stretch**
- **Flame Area Destruction**

These variables will also appear in the **Premixed Combustion...** category.

ANSYS Fluent also provides two additional reporting options for premixed combustion calculations with the G-Equation model:

- **Mean Distance from Flame**
- **Variance of Distance from Flame**

The **Variance of Distance from Flame** is the variance of the distance of the instantaneous flame from the mean flame position. These variables appear in the **Premixed Combustion...** category.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For additional information, see the following section:
16.5.1. Computing Species Concentrations

16.5.1. Computing Species Concentrations

If you know the composition of the unburnt and burnt mixtures in your model (that is, if you have performed separate ANSYS Fluent or external analyses of chemical equilibrium calculations or 1D premixed flames), you can compute the species concentrations in the domain using custom field functions:

- To determine the concentration of a species in the unburnt mixture, define the custom function $Y_u\left(1-c\right)$, where Y_u is the mass fraction for the species in the unburnt mixture (specified by you) and c is the value of the progress variable (computed by ANSYS Fluent).
- To determine the concentration of a species in the burnt mixture, define the custom function $Y_b c$, where Y_b is the mass fraction for the species in the burnt mixture (specified by you) and c is the value of the progress variable (computed by ANSYS Fluent).

See Custom Field Functions (p. 2003) for details about defining and using custom field functions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 17: Modeling Partially Premixed Combustion

ANSYS Fluent provides a partially premixed combustion model that is based on the non-premixed combustion model described in Modeling Non-Premixed Combustion (p. 1025) and the premixed combustion model described in Modeling Premixed Combustion (p. 1089). For information about the theory behind the partially premixed combustion model, see Partially Premixed Combustion in the *Fluent Theory Guide*. Information about using the partially premixed combustion model is presented in the following sections:

17.1. Overview and Limitations
17.2. Using the Partially Premixed Combustion Model

17.1. Overview and Limitations

For additional information, see the following sections:

17.1.1. Overview
17.1.2. Limitations

17.1.1. Overview

Partially premixed combustion systems are premixed flames with non-uniform fuel-oxidizer mixtures (equivalence ratios). Such flames include premixed jets discharging into a quiescent atmosphere, lean premixed combustors with diffusion pilot flames and/or cooling air jets, and imperfectly mixed inlets.

The partially premixed model in ANSYS Fluent is a combination of the non-premixed model (Modeling Non-Premixed Combustion (p. 1025)) and the premixed model (Modeling Premixed Combustion (p. 1089)). The premixed reaction-progress variable, c, determines the position of the flame front. Behind the flame front ($c=1$), the mixture is burnt and the equilibrium or laminar flamelet mixture fraction solution is used. Ahead of the flame front ($c=0$), the species mass fractions, temperature, and density are calculated from the mixed but unburnt mixture fraction.

ANSYS Fluent offers two types of partially premixed combustion models, namely Thin Flamelet and Flamelet Generated Manifold (FGM).

The Thin Flamelet model assumes that the premixed flame front is infinitely thin, and that within the flame brush ($0<\overline{c}<1$), the thermochemistry is described by a linear combination of unburnt and burnt mixtures. The composition of the burnt mixture can be chemical equilibrium or steady diffusion laminar flamelets.

The FGM model assumes that the thermochemical states in a turbulent flame are similar to the states in a laminar flame, and parameterize these by mixture fraction and reaction progress. Within the laminar flame, reaction progress increases from $c=0$ in the unburnt reactants to $c=1$ in the burnt products, over a finite flame thickness. The FGM can be modeled with either premixed or diffusion laminar flames.

17.1.2. Limitations

- The underlying theory, assumptions, and limitations of the non-premixed and premixed models apply directly to the partially premixed model. In particular, the single-mixture-fraction approach is limited to two inlet

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

streams, which may be pure fuel, pure oxidizer, or a mixture of fuel and oxidizer. The two-mixture-fraction model extends the number of inlet streams to three, but incurs a major computational overhead. See Limitations of the Premixed Combustion Model (p. 1090) for additional limitations.

- The Flamelet Generated Manifold (FGM) model is limited to the C-Equation partially-premixed model.

17.2. Using the Partially Premixed Combustion Model

The procedure for setting up and solving a partially premixed combustion problem combines parts of the non-premixed combustion setup and the premixed combustion setup. An outline of the procedure is provided in Setup and Solution Procedure (p. 1100), along with information about where to look in the non-premixed and premixed combustion chapters for details. Inputs that are specific to the partially premixed combustion model are provided in this chapter.

Information is provided in the following sections:

17.2.1. Setup and Solution Procedure
17.2.2. Importing a Flamelet
17.2.3. Flamelet Generated Manifold
17.2.4. Calculating the Look-Up Tables
17.2.5. Standard Files for Flamelet Generated Manifold Modeling
17.2.6. Modifying the Unburnt Mixture Property Polynomials
17.2.7. Modeling In Cylinder Combustion

17.2.1. Setup and Solution Procedure

1. Read your mesh file into ANSYS Fluent and set up any other models you plan to use in conjunction with the partially premixed combustion model (turbulence, radiation, and so on).

2. Enable the partially premixed combustion model.

   a. Turn on the **Partially Premixed Combustion** model in the **Species Model** dialog box.

   Note

   Make sure a turbulence model (other than the Spalart-Allmaras model) is selected before selecting a combustion model.

   Setup → **Models** → **Species** **Edit...**

   b. If you select the **C Equation** as the **Premixed Model**, then you have the choice of selecting one of the following **State Relation** models in the **Chemistry** tab: **Chemical Equilibrim**, **Steady Diffusion Flamelet**, **Unsteady Diffusion Flamelet** (for steady-state simulations starting from a converged Steady Diffusion Flamelet solution), or **Flamelet Generated Manifold**.

   c. If you select the **Extended Coherent Flame Model**, then you can select **Chemical Equilibrim**, **Steady Diffusion Flamelet**, and **Unsteady Diffusion Flamelet**. You can modify the **Extended Coherent Flamelet Model Constants** in the **Premix** tab. See Modifying the Constants for the ECFM Flame Speed Closure (p. 1095) for details.

   d. If you select the **G Equation** as the **Premixed Model**, then you have the choice of selecting one of the following **State Relation** models in the **Chemistry** tab: **Chemical Equilibrim** or **Steady Diffusion Flamelet**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the **Chemistry** tab of the **Species Model** dialog box, select the appropriate **State Relation** based on the type of partially premixed model you want to simulate. In ANSYS Fluent, there are two types of partially premixed models, namely a thin-flamelet model (equilibrium and diffusion flamelet) and a finite-thickness flamelet model, which is a Flamelet Generated Manifold. You can refer to Non-Premixed Combustion in the *Fluent Theory Guide* to learn about diffusion flamelets or Partially Premixed Combustion Theory in the *Fluent Theory Guide* for FGMs. Also, you can refer to Overview in the *Fluent Theory Guide* for general information about the thin-flamelet and finite-thickness flamelet models.

4. If you select **Flamelet Generated Manifold**, you will also need to define whether the FGM is calculated from a premixed or a diffusion flamelet, as well as the **Turbulence-Chemistry Interaction** in the **Premix** tab. The three options (**Finite-Rate**, **Turbulent Flame Speed**, and **Finite-Rate/Turbulent Flame Speed**) are discussed in FGM Turbulent Closure in the *Fluent Theory Guide*.

   Note

   The **Finite-Rate/Turbulent Flame Speed** option uses the minimum of finite-rate and turbulent flame speed as discussed in the FGM Turbulent Closure in the *Fluent Theory Guide*. In the mixing layer regions, the adjacent cells could have different rate determining steps, which causes spurious species generation like generation of a product species. This can be minimized by selecting only **Turbulent Flame Speed** option.

5. In the **Flamelet** tab, you can modify the **Flamelet Parameters** as described in Flamelet Generated Manifold (p. 1103).

6. Generate a PDF look-up table. The table parameters are defined in Calculating the Look-Up Tables (p. 1105).

   Important

   If ANSYS Fluent warns you during the partially premixed properties calculation that any parameters are out of the range for the laminar flame speed function, you will need to modify the piecewise-linear points manually before saving the PDF file. See Modifying the Unburnt Mixture Property Polynomials (p. 1110) for details. Also, the calculation of the thermal diffusivity uses the thermal conductivity in the **Create/Edit Materials** dialog box. More accurate thermal diffusivity polynomials can be obtained by editing the thermal conductivity in the **Create/Edit Materials** dialog box and then clicking **Recalculate Properties** in the **Properties** tab.

7. Define the physical properties for the unburnt material in the domain.

   Setup → Materials

   ANSYS Fluent will automatically select the **prepdf-polynomial** function for **Laminar Flame Speed**, indicating that the piecewise-linear polynomial function from the PDF look-up table will be used to compute the laminar flame speed. You may also choose to enter a **constant** value, use a **user-defined** function, or apply the **metghalchi-keck-law** instead of a piecewise-linear polynomial function. See Laminar Flame Speed in the *Fluent Theory Guide* and Defining Physical Properties for the Unburnt Mixture (p. 1093) for information about setting the other properties for the unburnt material.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

8. Set the values for the mean progress variable ($\overline{c}$) and the mean mixture fraction ($\overline{f}$) and its variance ($\overline{f'^2}$) at flow inlets and exits. (For problems that include a secondary stream, you will define boundary conditions for the mean secondary partial fraction and its variance as well.)

   Setup → **Boundary Conditions**

   See Defining Non-Premixed Boundary Conditions (p. 1079) for guidelines on setting mixture fraction and variance conditions, as well as thermal and velocity conditions at inlets.

   Important

   There are two ways to specify a premixed inlet boundary condition:

   a. If you defined the fuel composition in the **Boundary** tab to be the premixed inlet species, then you should set $\overline{f}=1$ and $\overline{c}=0$ in the boundary condition dialog boxes.

   b. If you set the fuel composition to pure fuel in the **Boundary** tab, you will need to set the correct equivalence ratio ($0<\overline{f}<1$) and $\overline{c}=0$ at your premixed inlet boundary condition.

   For example, if the premixed inlet of methane and air is at an equivalence ratio of 0.3, you can

   a. specify the mass fraction of the fuel composition of Y_{CH_4} = 0.017, Y_{O_2} = 0.236, and Y_{N_2} = 0.747 in the **Boundary** tab and $\overline{f}$ = 1 and $\overline{c}$ = 0 in the boundary condition dialog box.

   b. specify the mass fraction of the fuel composition of Y_{CH_4} = 1.0 in the **Boundary** tab and $\overline{f}$ = 0.017 and $\overline{c}$ = 0 in the boundary condition dialog box.

      Method (a) is preferred since it will have more points in the flame zone than method (b).

9. Initialize the value of the progress variable.

   Solution → **Initialization** → **Patch...**

   See Initializing the Progress Variable (p. 1094) for details.

10. Solve the problem and perform postprocessing.

    See Solving the Flow Problem (p. 1083) for guidelines about setting solution parameters. (These guidelines are for non-premixed combustion calculations, but they are relevant for partially premixed as well.)

17.2.2. Importing a Flamelet

To import an existing flamelet file

1. Select the **Import Flamelet** option in the **Chemistry** tab of the **Species Model** dialog box.

2. Click the **Import Flamelet File...** button. In The Select File Dialog Box (p. 19), select the file to be read in to ANSYS Fluent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

After you have completed this step, you can skip ahead to the **Table** tab of the **Species Model** dialog box (see Calculating the Look-Up Tables (p. 1105)).

17.2.3. Flamelet Generated Manifold

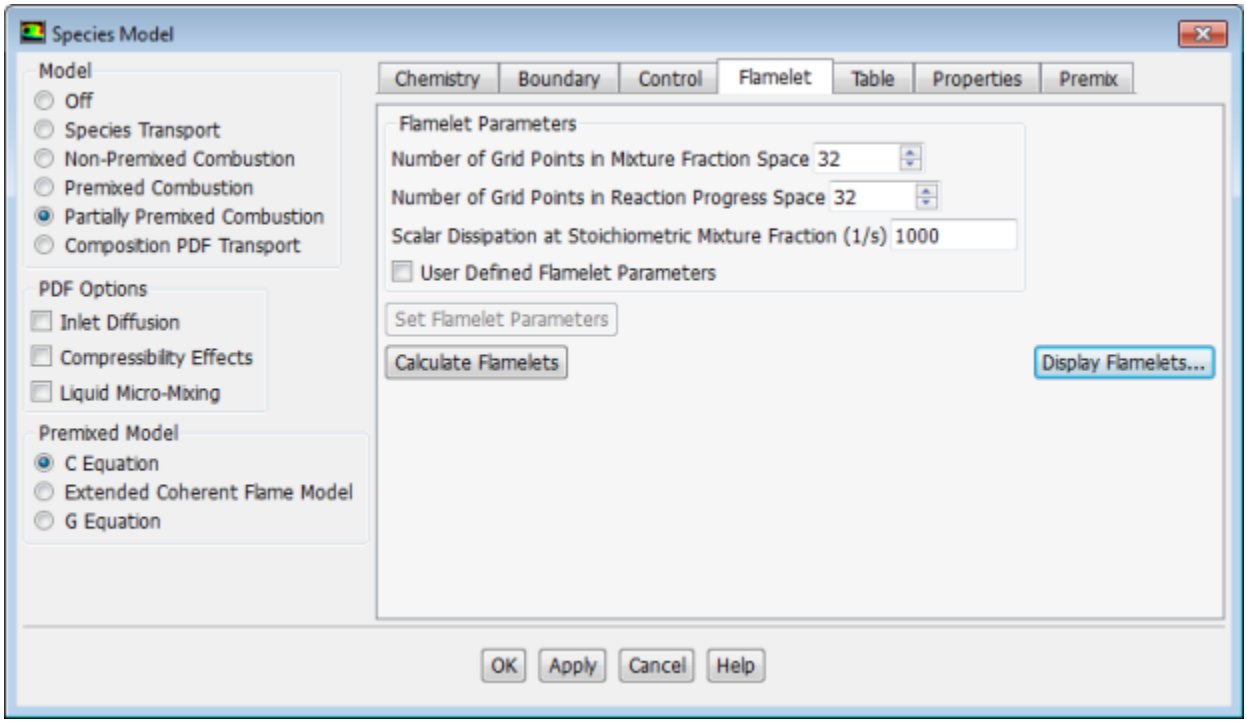
The ANSYS Fluent Flamelet Generated Manifold (FGM) model has several advantages over the thin-flame equilibrium or diffusion steady flamelet models, such as the ability to model flame quenching due to dilution. The manifold can be modeled with either a **Premixed Flamelet** or a **Diffusion Flamelet**.

To generate a flamelet file, go to the **Flamelet** tab of the **Species Model** dialog box (Figure 15.16: The Species Model Dialog Box (Flamelet Tab) (p. 1057)), where you will enter values for parameters of the flamelet.

Premixed Flamelet Generated Manifolds

For premixed Flamelet Generated Manifolds, details about specifying the Scalar Dissipation at Stoichiometric Mixture Fraction can be found in Premixed FGMs in the *Fluent Theory Guide*.

Figure 17.1: Premixed Flamelet Generated Manifolds (Flamelet Tab)



The **Flamelet Parameters** for premixed FGMs are as follows:

Number of Grid Points in Mixture Fraction Space

specifies the number of mixture fraction grid points distributed between the oxidizer ($f=0$) and the fuel ($f=1$). Increased resolution will provide greater accuracy, but since premixed flamelets are solved at all mixture fraction points, the solution time will increase linearly with this input.

Number of Grid Points in Reaction Progress Space

specifies the number of reaction progress grid points distributed between unburnt ($c=0$) and burnt ($c=1$) states. Increased resolution will provide greater accuracy, but since the premixed flamelet species and temperature are solved coupled and implicit in c space, the solution time and memory requirements increase greatly with the number of c grid points.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scalar Dissipation at Stoichiometric Mixture Fraction

specifies the premixed flamelet strain rate. The default of 1000/s is an approximate value of the scalar dissipation of a freely propagating (unstrained) premixed flame at stoichiometric mixture fraction (unity equivalence ratio).

User Defined Flamelet Parameters

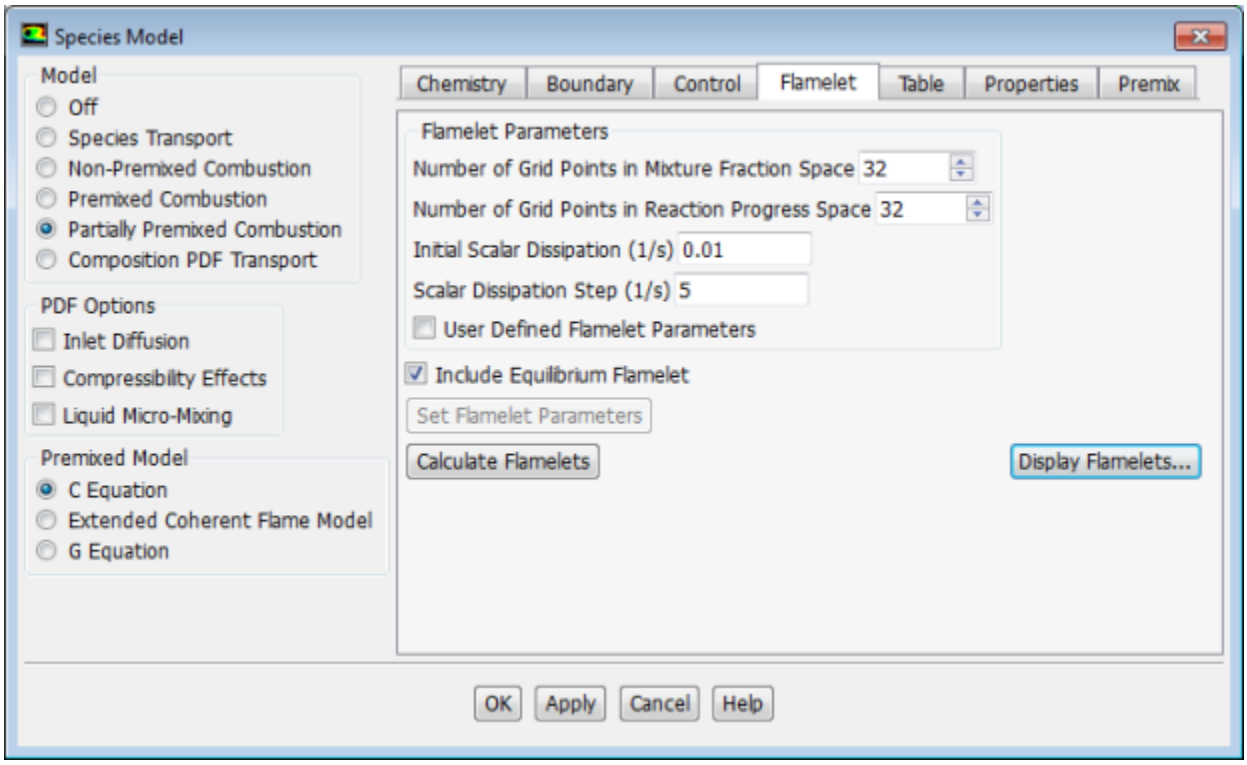
enables you to hook a user-defined function for scalar dissipation and mean mixture fraction (or progress variable) grid discretization

Click **Calculate Flamelets** to begin the premixed flamelet calculation.

Diffusion Flamelet Generated Manifolds

Generating diffusion Flamelet Generated Manifolds is similar to generating Steady Diffusion Flamelets, as described in Calculating the Flamelets (p. 1056).

Figure 17.2: Premixed Diffusion Flamelet Generated Manifolds (Flamelet Tab)



The parameters for the diffusion FGM flamelet are slightly different than those for the premixed FGM flamelet. The additional diffusion FGM flamelet parameters are as follows:

Initial Scalar Dissipation

is the scalar dissipation of the first flamelet in the library. This corresponds to χ_0 in Equation 8.52 in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Scalar Dissipation Step

specifies the interval between scalar dissipation values (in s^{-1}) for which multiple flamelets will be calculated. This corresponds to $\Delta\chi$ in Equation 8.52 in the Theory Guide.

Note

The FGM model does not require the **Maximum Number of Flamelets** parameter. Instead, ANSYS Fluent increases the scalar dissipation until the flamelet extinguishes. Hence, the **Scalar Dissipation Step** should be set at approximately one twentieth of the counterflow diffusion flamelet extinction strain rate, so that about twenty flamelets are calculated. The final, extinguishing unsteady diffusion flamelet is used to model the manifold between the unburnt state (c=0) and the last steady diffusion flamelet at the highest scalar dissipation rate just before extinction.

Include Equilibrium Flamelet

determines how the progress variable (Equation 9.2 in the *Fluent Theory Guide*) is calculated. If this option is selected, ANSYS Fluent will compute the progress variable using equilibrium. Otherwise, the progress variable will be computed using the solution of flamelet generated with initial scalar dissipation as a denominator in Equation 9.2 in the *Fluent Theory Guide*.

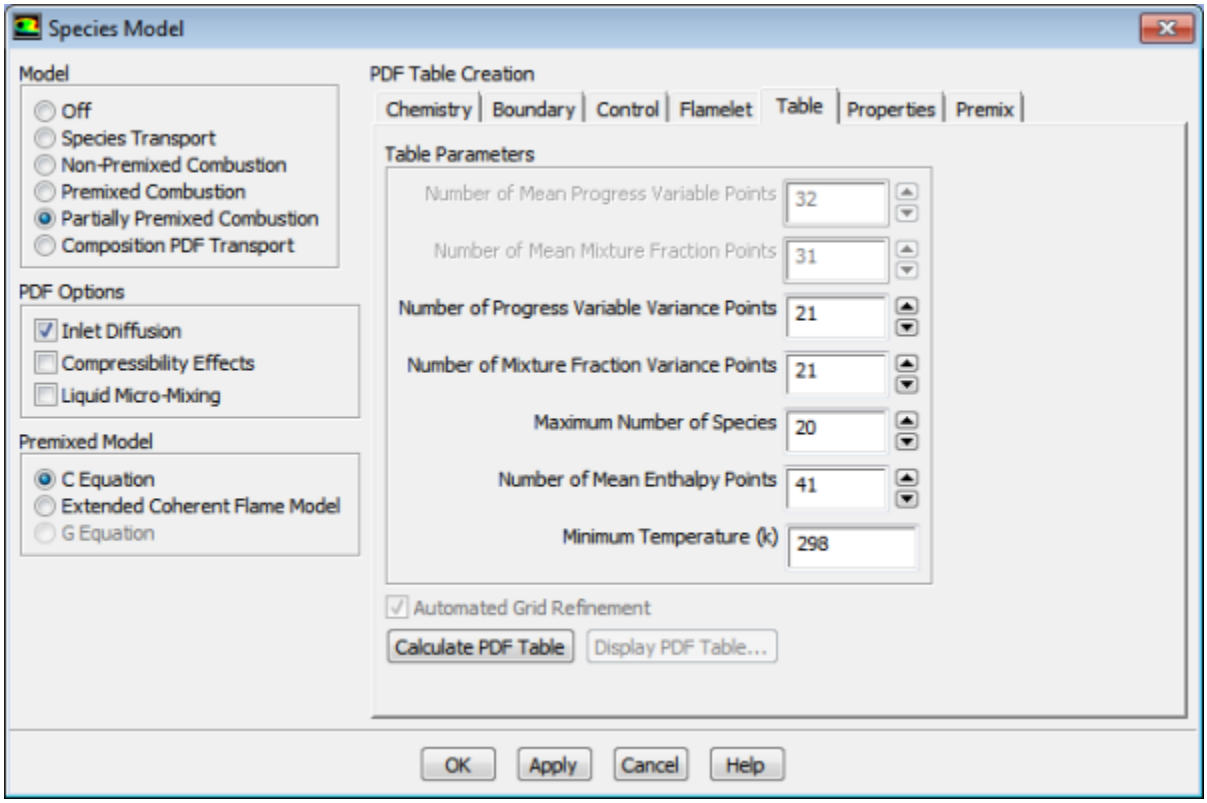
17.2.4. Calculating the Look-Up Tables

ANSYS Fluent requires additional inputs that are used in the creation of the look-up tables. Several of these inputs control the number of discrete values for which the look-up tables will be computed. These parameters are input in the **Table** tab of the **Species Model** dialog box.

For the example of modeling a partially-premixed flame with either the premixed or the diffusion FGM model, the **Table** tab of the **Species Model** dialog box is shown in Figure 17.3: The Species Model Dialog Box (Table Tab) (p. 1106).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 17.3: The Species Model Dialog Box (Table Tab)



The look-up table parameters are as follows:

Number of Mean Progress Variable Points

is the number of discrete values of $\overline{c}$ at which the look-up tables will be computed. This number is determined from the number of grid points in the flamelet.

Number of Progress Variable Variance Points

is the number of discrete values of $\overline{c'^2}$ at which the look-up tables will be computed. Lower resolution is acceptable because the variation along the $\overline{c'^2}$ axis is, in general, not as steep as the variation along the $\overline{c}$ axis of the look-up tables.

Maximum Number of Species

is the maximum number of species that will be included in the look-up tables. The maximum number of species that can be included is 200. ANSYS Fluent will automatically select the species with the largest mole fractions to include in the PDF table. Note that the PDF table values of density and specific heat are pre-calculated with all the species, and hence the convergence behavior of ANSYS Fluent will not be affected by the input for the **Maximum Number of Species**. Hence, to keep table sizes small, you should set the **Maximum Number of Species** to only include the species that you are interested in postprocessing.

Number of Mean Enthalpy Points

is the number of discrete values of enthalpy at which the look-up tables will be computed. This input is required only if you are modeling a non-adiabatic system. The number of points required will depend on the chemical system that you are considering, with more points required in high heat release systems (for example, hydrogen/oxygen flames).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Minimum Temperature
is used to determine the lowest temperature for which the look-up tables are generated. Your input should correspond to the minimum temperature expected in the domain (for example, an inlet or wall temperature). The minimum temperature should be set 10–20 K below the minimum system temperature. This option is available only if you are modeling a non-adiabatic system.

When you are satisfied with your inputs, click **Calculate PDF Table** to generate the look-up tables.

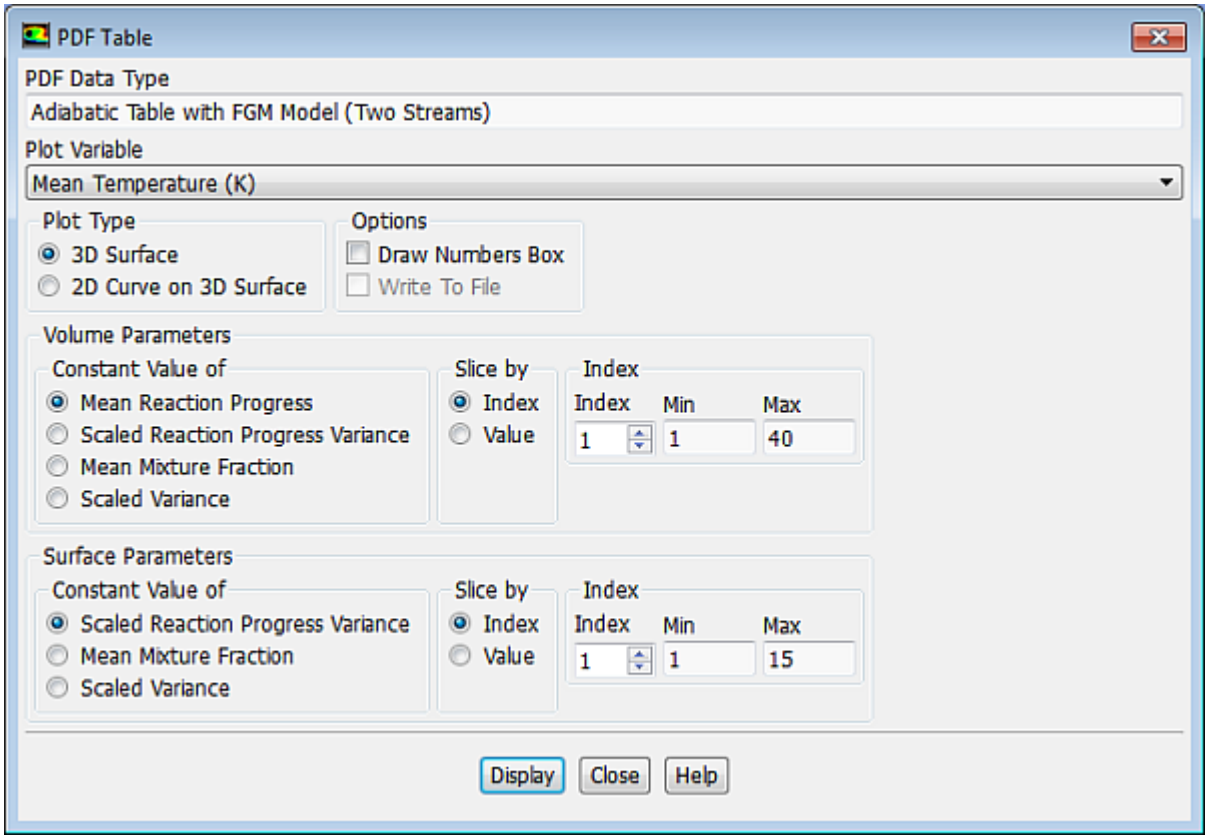
17.2.4.1. Postprocessing the Look-Up Tables with Flamelet Generated Manifolds

For the FGM model, the PDF table is four-dimensional for adiabatic cases and five-dimensional for non-adiabatic cases. For adiabatic PDF tables, the four independent variables are Mean mixture fraction, Mean reaction progress variable, Mixture fraction variance, and Progress variable variance. For non-adiabatic tables, the additional fifth independent variable is enthalpy. The FGM PDF tables can be post-processed using 2D curves and 3D surfaces by fixing two or more independent variables.

The procedure to display the lookup tables graphically is similar to that outlined in Postprocessing the Look-Up Table Data (p. 1068) with additional steps as follows.

- Adiabatic PDF Tables

Figure 17.4: The PDF Table Dialog Box (Adiabatic Case With FGM)



– 3D surfaces:

1. Under **Volume Parameters**, select the discrete independent parameter to be held constant and fix it by specifying either a slice **Index** number or a **Value**. (For more information, see Postprocessing the Look-Up Table Data (p. 1068).)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. In a similar manner, under **Surface Parameters**, select and fix the second discrete independent parameter and click **Plot**.

   The resulting plot is a 3D surface of the selected **Plot Variable** as a function of the remaining two independent variables that have not been fixed.

– 2D curves on 3D Surface:

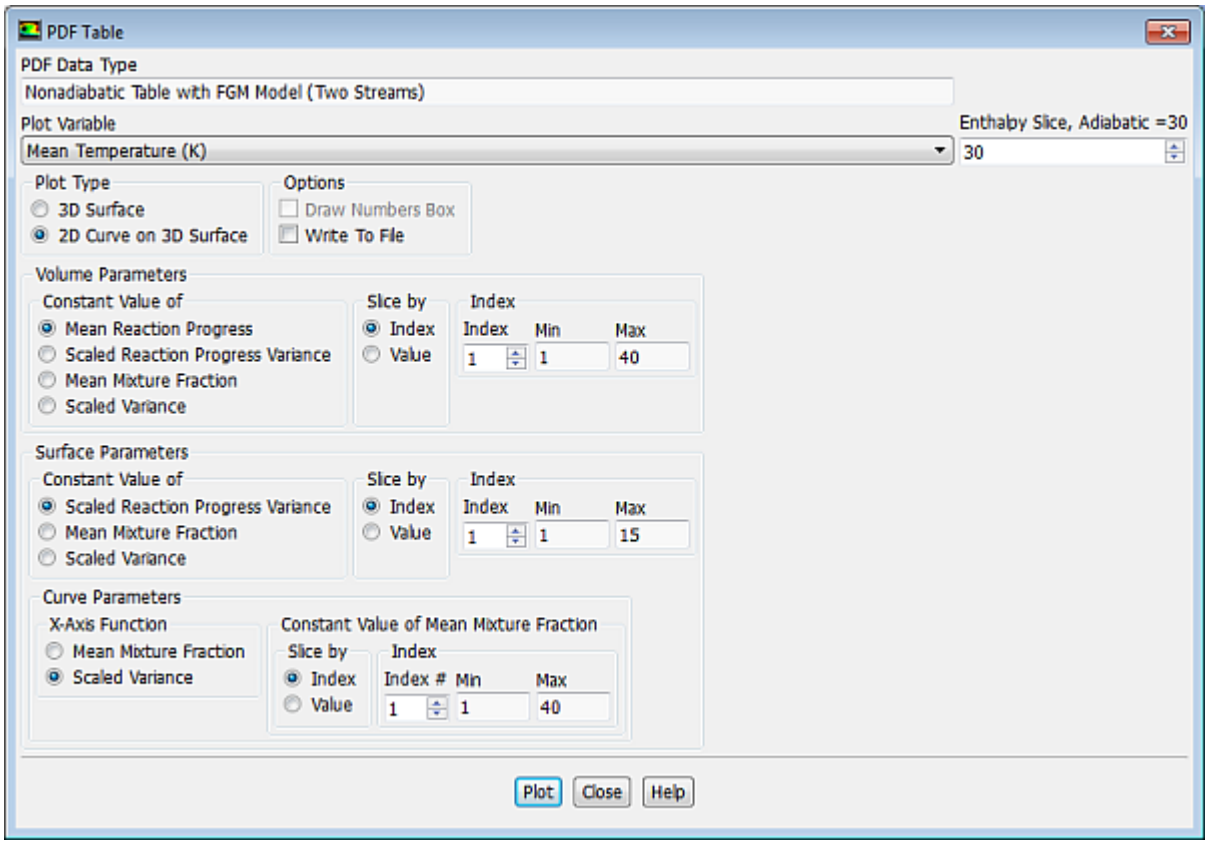
1. Under **Volume Parameters** and **Surface Parameters**, fix discrete independent parameters as described above.

2. Under the **Curve Parameters** group box, select the **X-Axis Function** against which the plot variable will be displayed, fix the remaining discrete independent parameter using controls in the **Constant Value of *`Independent Parameter`*** group box, and click **Plot**.

   The resulting plot is a 2D curve of the selected **Plot Variable** as a function of the remaining independent variable that has not been fixed.

• Non-Adiabatic PDF Tables

Figure 17.5: The PDF Table Dialog Box (Non-Adiabatic Case With FGM)



1. Fix the enthalpy slice level by specifying **Enthalpy Slice**.

   For non-adiabatic PDF tables, heat loss/gain is the fifth independent variable, which is expressed as enthalpy levels. By default, the enthalpy level is fixed at the adiabatic level, which is displayed in the **Enthalpy Slice, Adiabatic = *`slice number`*** label, as shown in Figure 17.5: The PDF Table Dialog Box (Non-Adiabatic Case With FGM) (p. 1108). Enthalpy slice numbers below the adiabatic

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

slice number are associated with heat loss, while enthalpy slice numbers above the adiabatic slice number are associated with enthalpy gain.

2. Depending on whether you want to display a 3D surface or a 2D Curve on 3D Surface, follow appropriate steps for Adiabatic PDF Tables described above.

17.2.5. Standard Files for Flamelet Generated Manifold Modeling

A standard flamelet file format can be used to read and write FGM flamelets. The data structure for the standard flamelet file format is based on keywords that precede each data section. If any of the keywords in your flamelet data file do not match the supported keywords, you will have to manually edit the file and change the keywords to one of the supported types. (The ANSYS Fluent flamelet filter is case-insensitive, so you need not worry about capitalization within the keywords.)

The following keywords are supported by the ANSYS Fluent filter:

- Header section: `HEADER`
- Main body section: `BODY`
- Number of species: `NUMOFSPECIES`
- Number of grid points: `GRIDPOINTS`

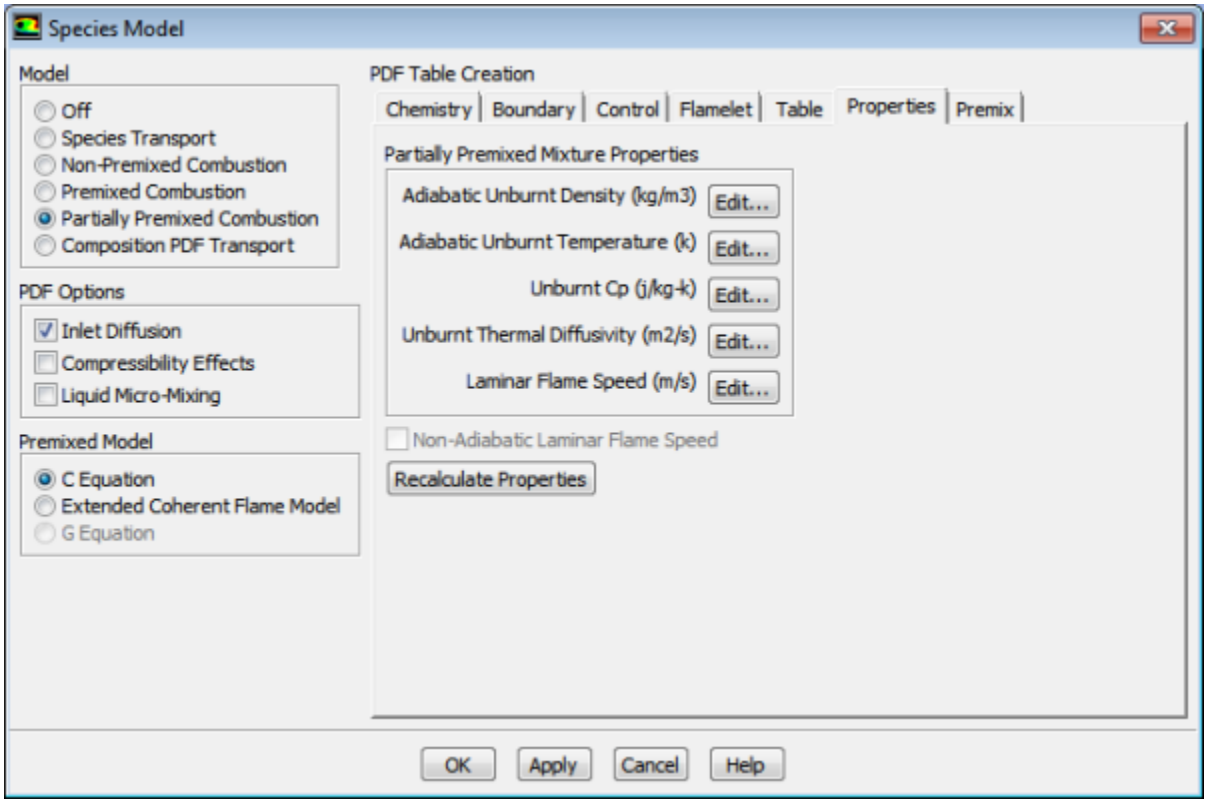
17.2.6. Modifying the Unburnt Mixture Property Polynomials

After building the PDF table, ANSYS Fluent automatically calculates the temperature, density, heat capacity, and thermal diffusivity of the unburnt mixture as polynomial functions of the mean mixture fraction, $\overline{f}$ (see Equation 10.20 in the *Fluent Theory Guide*). The laminar flame speed is automatically calculated as a piecewise-linear polynomial function of $\overline{f}$.

However, as outlined in Partially Premixed Combustion Theory in the *Fluent Theory Guide*, the laminar flame speed depends on details of the chemical kinetics and molecular transport properties, and is not calculated directly. Instead, curve fits are made to flame speeds determined from detailed simulations [38] (p. 2889). These fits are limited to a range of fuels (H_2, CH_4, C_2H_2, C_2H_4, C_2H_6, and C_3H_8), air as the oxidizer, equivalence ratios of the lean limit through unity, unburnt temperatures from 298 K to 800 K, and pressures from 1 bar to 40 bars. If your parameters fall outside this range, ANSYS Fluent will warn you when it computes the look-up table. In this case, you will need to modify the piecewise-linear points in the **Properties** tab of the **Species Model** dialog box (Figure 17.6: The Species Model Dialog Box (Properties Tab) (p. 1111)) before you save the PDF file.

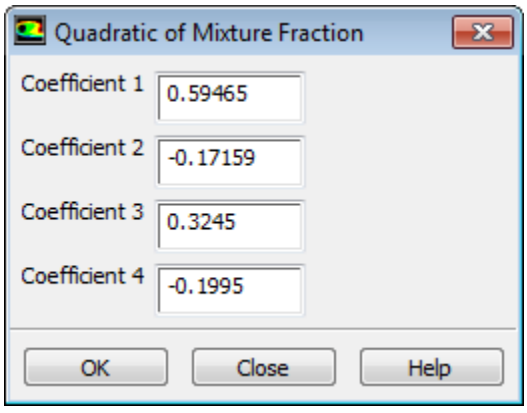
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 17.6: The Species Model Dialog Box (Properties Tab)



For each polynomial function of $\overline{f}$ under **Partially Premixed Mixture Properties** (**Adiabatic Unburnt Density**, **Adiabatic Unburnt Temperature**, **Unburnt Cp**, and **Unburnt Thermal Diffusivity**), you can specify values for **Coefficient 1**, **Coefficient 2**, **Coefficient 3**, and **Coefficient 4** (the polynomial coefficients in Equation 10.20 in the *Fluent Theory Guide*) in the appropriate **Quadratic of Mixture Fraction** dialog box (Figure 17.7: The Quadratic of Mixture Fraction Dialog Box (p. 1111)). To open this dialog box, click the appropriate **Edit...** button in the **Properties** tab.

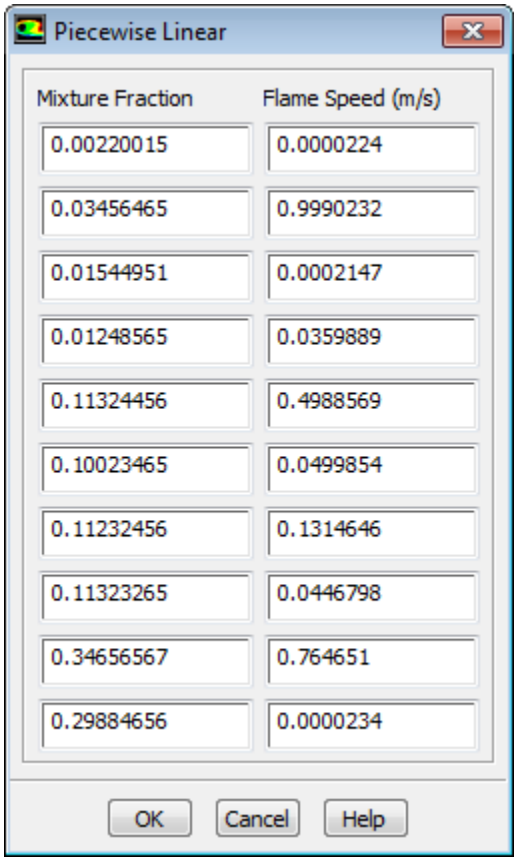
Figure 17.7: The Quadratic of Mixture Fraction Dialog Box



You can also specify the piecewise-linear **Mixture Fraction** and its corresponding **Laminar Flame Speed** for 10 different points in the **Piecewise Linear** dialog box (Figure 17.8: The Piecewise Linear Dialog Box (p. 1112)). The first set of values is the lower limit and the last set of values is the upper limit. Outside of either limit, the laminar flame speed is constant and equal to that limit. To open this dialog box, click the **Edit...** button next to **Laminar Flame Speed** in the **Properties** tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 17.8: The Piecewise Linear Dialog Box



Important

Note also that if you choose to use a user-defined function for the laminar flame speed in the Create/Edit Materials Dialog Box (p. 2302), the piecewise-linear fit becomes irrelevant.

If the secondary mixture fraction model is enabled, the unburnt properties are a function of both the mean and secondary mixture fractions. An additional column is added in the **Piecewise Linear** dialog box for the secondary mixture fraction unburnt polynomial coefficients.

Note that the **Non-Adiabatic Laminar Flame Speed** option when enabled includes the non-adiabatic effects on the laminar flame speed by tabulating the laminar speeds in the PDF table. See Laminar Flame Speed in the *Fluent Theory Guide*.

17.2.7. Modeling In Cylinder Combustion

Each of the partially premixed combustion models may be used for modeling in cylinder combustion. When modeling more than one cycle of such engines, you may choose to model trapped combustion products and exhaust gas recirculation (EGR) using the inert species model (see Setting Up the Inert Model (p. 1075)). A **Dynamic Mesh Event** has also been provided for calculating the inert composition, converting burned gases to inert and resetting the combustion process ready for the next cycle (see Resetting Inert EGR (p. 722) and Resetting Inert EGR (p. 1077)).

In the case of the G-Equation model, this is the only way to automatically model multiple in cylinder combustion cycles and take into account trapped burned gases remaining in the cylinder from one cycle to the next.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 18: Modeling a Composition PDF Transport Problem

ANSYS Fluent provides a composition PDF transport model for modeling finite-rate chemistry in turbulent flames. For information about the theory behind the composition PDF transport model, see Composition PDF Transport in the Theory Guide. Information about using this model is presented in the following sections:

18.1. Overview and Limitations
18.2. Steps for Using the Composition PDF Transport Model
18.3. Enabling the Lagrangian Composition PDF Transport Model
18.4. Enabling the Eulerian Composition PDF Transport Model
18.5. Initializing the Solution
18.6. Monitoring the Solution
18.7. Postprocessing for Lagrangian PDF Transport Calculations
18.8. Postprocessing for Eulerian PDF Transport Calculations

18.1. Overview and Limitations

The composition PDF transport model, like the Laminar Finite-Rate (see Direct Use of Finite-Rate Kinetics (no TCI) in the Theory Guide) and EDC model (see The Eddy-Dissipation-Concept (EDC) Model in the Theory Guide), should be used when you are interested in simulating finite-rate chemical kinetic effects in turbulent reacting flows. With an appropriate chemical mechanism, kinetically-controlled species such as CO and NOx, as well as flame extinction and ignition, can be predicted. PDF transport simulations are computationally expensive, and it is recommended that you start your modeling with small meshes, and preferably in 2D.

A limitation that applies to the composition PDF transport model is that you must use the pressure-based solver as the model is not available with the density-based solver.

ANSYS Fluent has two different discretizations of the composition PDF transport equation, namely Lagrangian and Eulerian. The Lagrangian method is more accurate than the Eulerian method, but requires significantly longer run time to converge.

18.2. Steps for Using the Composition PDF Transport Model

The procedure for setting up and solving a composition PDF transport problem is outlined below, and then described in detail. Remember that only steps that are pertinent to composition PDF transport modeling are shown here. For information about inputs related to other models that you are using in conjunction with the composition PDF transport model, see the appropriate sections for those models.

1. Read a CHEMKIN-formatted gas-phase mechanism file and the associated thermodynamic data file in the **CHEMKIN Mechanism** dialog box (see Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

File → Import → CHEMKIN Mechanism...

Important

If your chemical mechanism is not in CHEMKIN format, you will have to enter the mechanism into ANSYS Fluent as described in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958).

2. Enable a turbulence model.

   Setup → Models → Viscous Edit...

3. Enable the **Composition PDF Transport** model and set the related parameters. Refer to Enabling the Lagrangian Composition PDF Transport Model (p. 1115) and Enabling the Eulerian Composition PDF Transport Model (p. 1118) for further details.

   Setup → Models → Species Edit...

4. Check the material properties in the **Create/Edit Materials** dialog box and the reaction parameters in the **Reactions** dialog box. The default settings should be sufficient.

   Setup → Materials

5. Set the operating conditions, cell zone conditions, and boundary conditions.

   Setup → Cell Zone Conditions → Operating Conditions...

   Setup → Boundary Conditions

6. Check the solver settings.

   Solution → Methods

   Solution → Controls

   The default settings should be sufficient, although you should change the discretization to second-order once the solution has converged.

7. Initialize the solution. You may need to patch a high-temperature region to ignite the flame.

   Solution → Initialization → Initialize

   Solution → Initialization → Patch...

8. Run the solution.

   Solution → Run Calculation

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

9. Solve the problem and perform postprocessing.

Important

A good initial condition can reduce the solution time substantially. You should start from an existing solution calculated using the Laminar Finite-Rate, EDC model, non-premixed combustion model, or partially premixed combustion model. See Modeling Species Transport and Finite-Rate Chemistry (p. 957), Modeling Non-Premixed Combustion (p. 1025), and Modeling Partially Premixed Combustion (p. 1099) for further information on such simulations.

18.3. Enabling the Lagrangian Composition PDF Transport Model

To enable the composition PDF transport model, select **Composition PDF Transport** in the **Species Model** dialog box (Figure 18.1: The Species Model Dialog Box for Lagrangian Composition PDF Transport (p. 1116)).

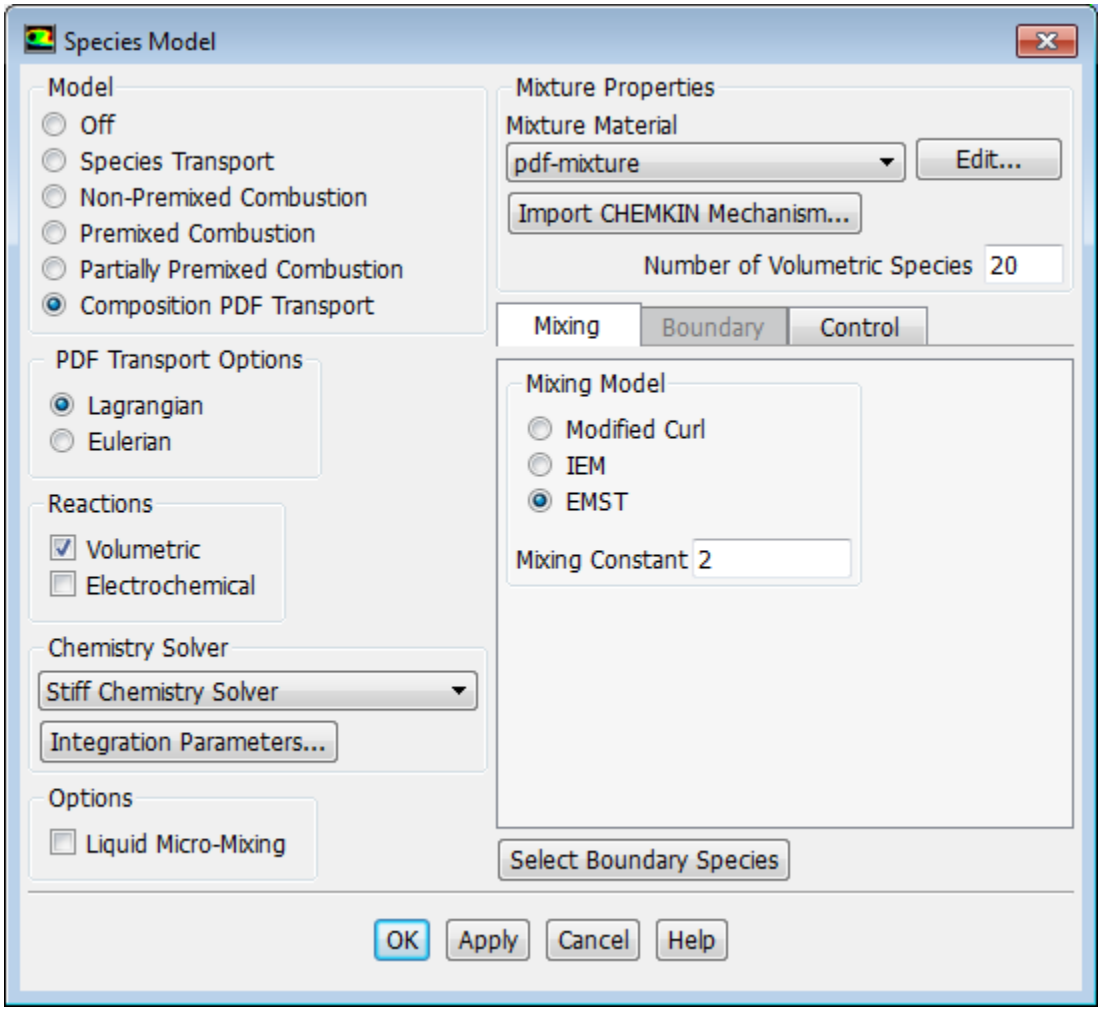
Setup → Models → Species Edit...

When you enable **Composition PDF Transport**, the dialog box will expand to show the relevant inputs.

1. Select **Lagrangian** under **PDF Transport Options**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 18.1: The Species Model Dialog Box for Lagrangian Composition PDF Transport



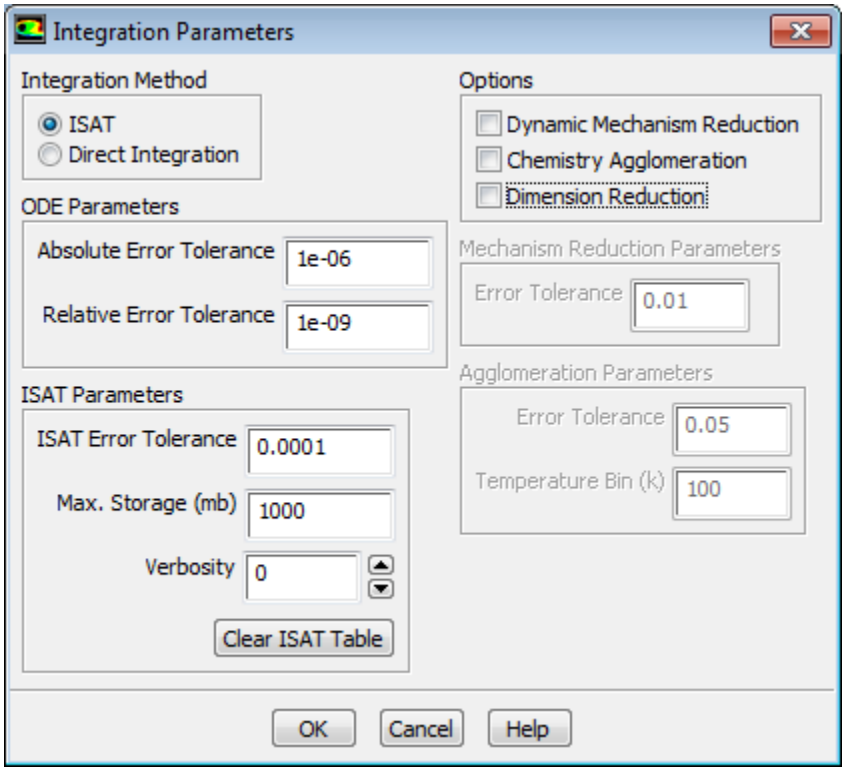
2. Enable **Volumetric** under **Reactions**.

   The **Composition Pdf Transport** model uses ANSYS Fluent stiff chemistry solver with ISAT enabled by default. See Using ISAT (p. 1128) for more details.

3. Click the **Integration Parameters...** button to open the Integration Parameters Dialog Box (p. 2235) (Figure 18.2: The Integration Parameters Dialog Box (p. 1117)). For additional information, see Using ISAT (p. 1128).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 18.2: The Integration Parameters Dialog Box



4. Enable **Liquid Micro-Mixing** to interpolate C_ϕ from turbulence models and scalar spectra, as noted in Liquid Reactions in the Theory Guide. This is applied to cases where reactions in liquids occur at low turbulence levels, among reactants with low diffusivities. Therefore, a default value of C_ϕ=2 may not be desirable, as it over-estimates the mixing rate.

5. In the **Mixing** tab, select **Modified Curl**, **IEM**, or **EMST** under **Mixing Model** and specify the value of the **Mixing Constant** (C_ϕ in Equation 11.6 in the Theory Guide). For more information about particle diffusion, see Particle Mixing in the Theory Guide.

> **Important**
>
> If the **Liquid Micro-Mixing** option is enabled, you cannot set the **Mixing Constant**.

6. You will not be specifying species boundary conditions in the **Boundary** tab. This is only applicable to the **Eulerian PDF Transport Option**.

7. In the **Control** tab, you will specify the Lagrangian PDF transport control parameters.

   Particles Per Cell
   sets the number of PDF particles per cell. Higher values of this parameter will reduce statistical error, but increase computational time.

   Local Time Stepping
   is available for steady-state simulations and can increase the convergence rate by taking maximum allowable time-steps on a cell-by-cell basis. (see Equation 11.4 of the Theory Guide). If **Local Time Stepping** is enabled, then you can specify the following parameters:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Convection #
specifies the particle convection number (see Δt_{conv} in Equation 11.4 in the Theory Guide).

Diffusion #
specifies the particle diffusion number (see Δt_{diff} in Equation 11.4).

Mixing #
specifies the particle mixing number (see Δt_{mix} in Equation 11.4).

18.4. Enabling the Eulerian Composition PDF Transport Model

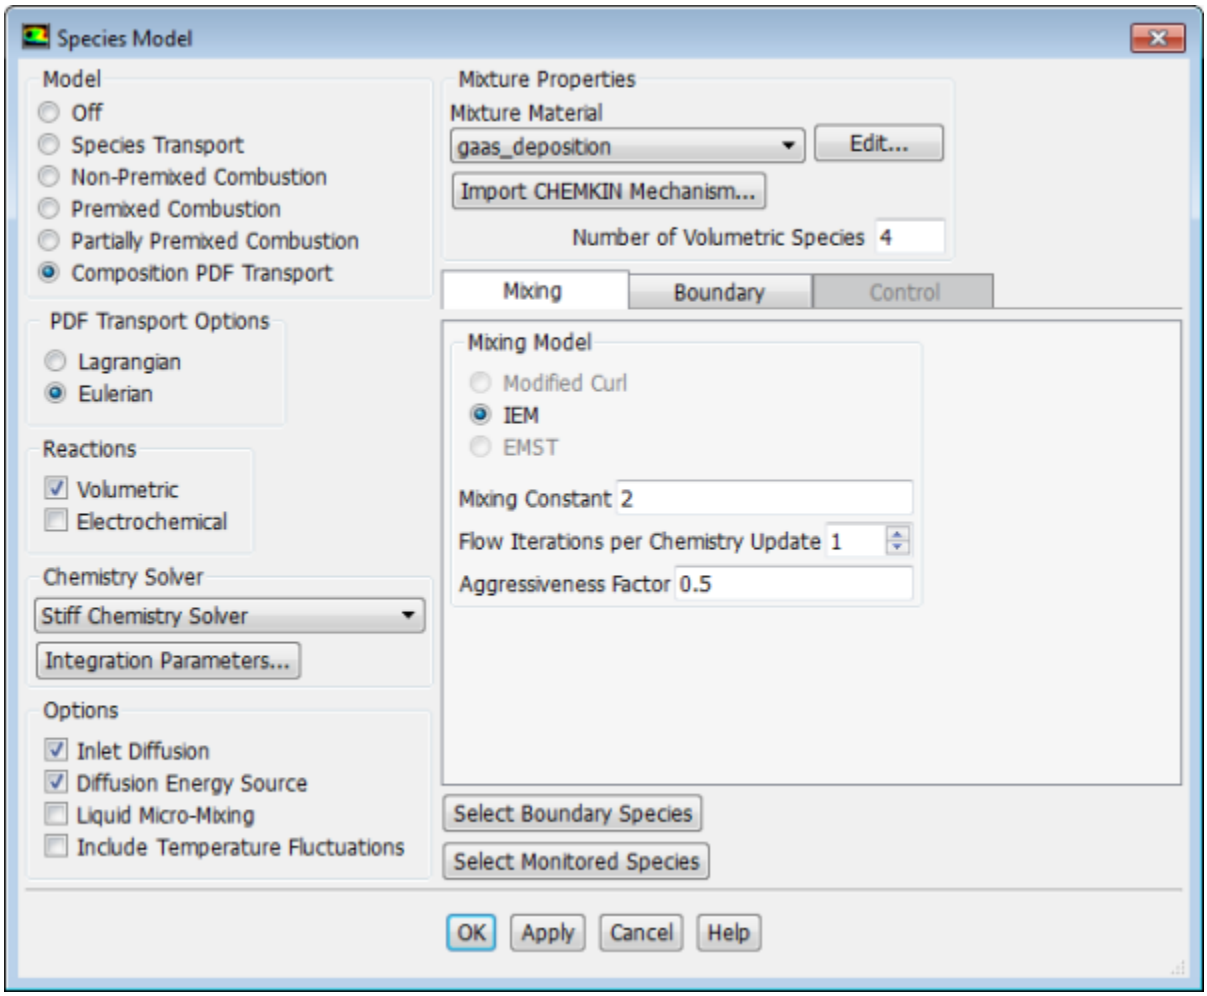
To enable the composition PDF transport model, select **Composition PDF Transport** in the **Species Model** dialog box (Figure 18.1: The Species Model Dialog Box for Lagrangian Composition PDF Transport (p. 1116)).

Setup → Models → Species Edit...

When you enable **Composition PDF Transport**, the dialog box will expand to show the relevant inputs.

1. Select **Eulerian** under **PDF Transport Options**.

Figure 18.3: The Species Model Dialog Box for Eulerian Composition PDF Transport



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Enable **Volumetric** under **Reactions**. The **Stiff Chemistry Solver** is disabled by default and should be enabled if the kinetic mechanism is numerically stiff.

3. Click the **Integration Parameters...** button to open the Integration Parameters Dialog Box (p. 2235) (Figure 18.2: The Integration Parameters Dialog Box (p. 1117)). See Using ISAT (p. 1128) for detailed information about this dialog box.

4. Enable **Inlet Diffusion** to include the diffusive transport of species through the inlets of your domain. Disable this option if the convective flux at one of the inlets is very small, resulting in mass loss by diffusion through that inlet.

5. Make sure that **Diffusion Energy Source** is enabled if you want to include species diffusion effects in the energy equation.

6. Enable **Liquid Micro-Mixing** if the fuel and oxidizer are liquids with low diffusivities (high Schmidt numbers). In this case, the **Mixing Constant** will be calculated according to Equation 11.13 in the Theory Guide.

7. By default, the Laminar (one mode) energy equation is solved, where temperature fluctuations are ignored. By enabling **Include Temperature Fluctuations**, the multi-mode energy equation will be solved as done for species.

8. In the **Mixing** tab, only the **IEM** mixing model is available for Eulerian PDF transport.

   a. Specify the value of the **Mixing Constant**. The default value is 2 for gas phase species.

   Important

   If the **Liquid Micro-Mixing** option is enabled, you cannot set the **Mixing Constant**.

   b. Enter the number of **Flow Iterations per Chemistry Update**. This is the frequency at which ANSYS Fluent will update the chemistry during the calculation. Increasing the number can reduce the computational expense of the chemistry calculations.

   c. Enter the **Aggressiveness Factor**. This is a numerical factor that controls the robustness and the convergence speed. This value ranges between 0 and 1, where 0 is the most robust, but results in the slowest convergence. The default value for the **Aggressiveness Factor** is 0.5.

9. In the **Boundary** tab, define the compositions of the fuel and oxidizer. You can select the boundary species to be displayed as described in Overview of the Problem Setup Procedure (p. 1026).

10. (**Eulerian** PDF Transport only) Optionally, you can select the monitored species as described in Overview of the Problem Setup Procedure (p. 1026).

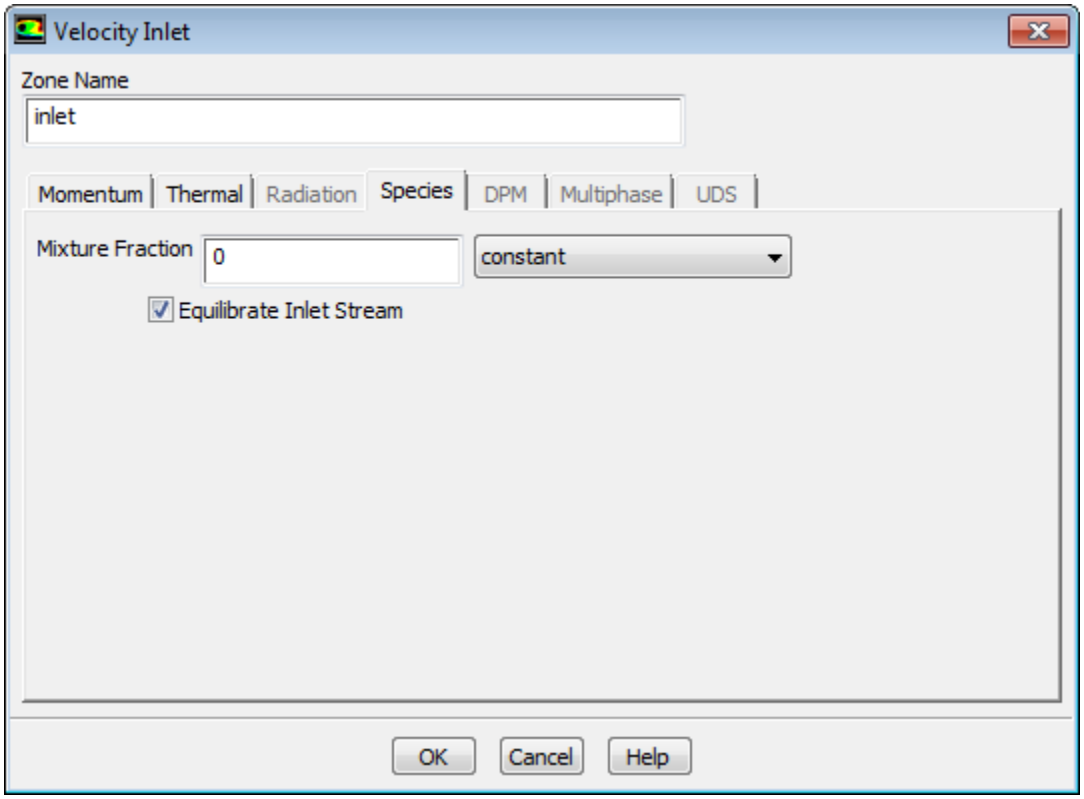
For additional information, see the following sections:
18.4.1. Defining Species Boundary Conditions

18.4.1. Defining Species Boundary Conditions

At flow inlets, specify the **Mixture Fraction** in the **Species** tab of the boundary condition inlet dialog boxes, as shown in Figure 18.4: The Velocity Inlet Dialog Box for Eulerian Composition PDF Transport (p. 1120). At outlet boundaries, similarly specify the **Backflow Mixture Fraction**. ANSYS Fluent always applies zero flux boundary conditions at walls for all species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 18.4: The Velocity Inlet Dialog Box for Eulerian Composition PDF Transport



18.4.1.1. Equilibrating Inlet Streams

The **Equilibrate Inlet Stream** option in the **Species** tab of the boundary conditions dialog boxes will set the inlet compositions to their chemical equilibrium values. This option can be used to model pilot flames and exhaust gas recirculation.

Important

This option should not be enabled for pure fuel or oxidizer inlets.

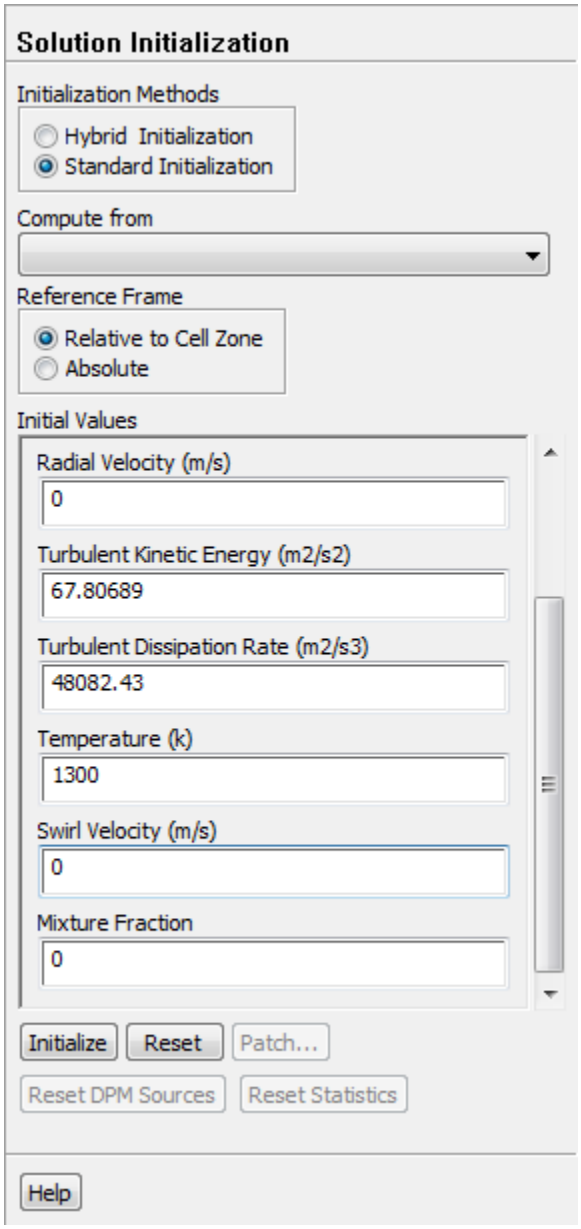
If you are using the Eulerian PDF transport model, specify the discretization and under-relaxation for the **Eulerian PDF** composition transport in the **Solution Controls** and **Solution Methods** task page.

18.5. Initializing the Solution

For the Eulerian PDF Transport model, the initialization variables are the mixture fraction and the temperature. The species mass fractions and enthalpy are calculated based on the fuel and oxidizer composition (specified in the **Species** dialog box) and the initialized mixture fraction and temperature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 18.5: The Solution Initialization Task Page for Eulerian Composition PDF Transport

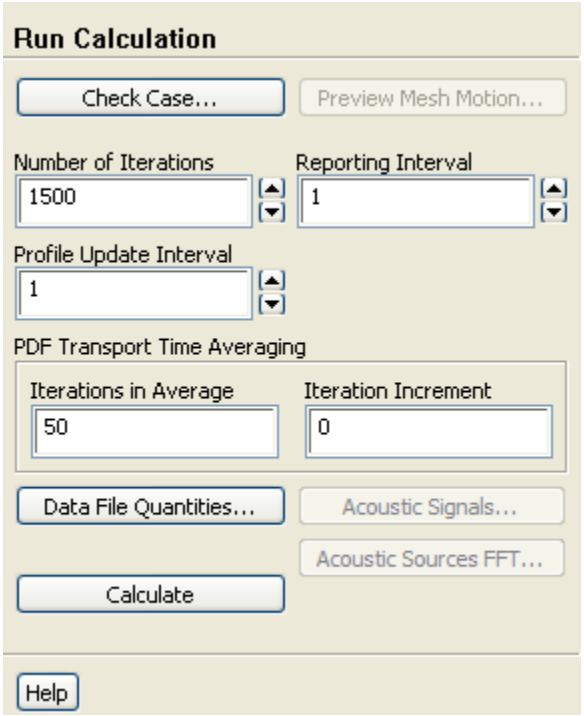


18.6. Monitoring the Solution

At low speeds, combustion couples to the fluid flow through density. The Lagrangian PDF transport algorithm has random fluctuations in the density field, which in turn causes fluctuations in the flow field. For steady-state flows, statistical fluctuations are decreased by averaging over a number of previous iterations in the **Run Calculation** task page (Figure 18.6: The Run Calculation Task Page for Composition PDF Transport (p. 1122)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 18.6: The Run Calculation Task Page for Composition PDF Transport



Averaging reduces statistical fluctuations and stabilizes the solution. However, ANSYS Fluent often indicates convergence of the flow field before the composition fields (temperatures and species) are converged. You should lower the default convergence criteria in the Residual Monitors Dialog Box (p. 2789), and always check that the **Total Heat Transfer Rate** in the Flux Reports Dialog Box (p. 2613) is balanced. It is also recommended that you monitor temperature/species on outlet boundaries and ensure that these are steady.

The Lagrangian PDF method has the additional solution controls: **Iterations in Average** and **Iteration Increment**. By increasing the **Iterations in Average**, fluctuations are smoothed out and residuals level off at smaller values. However, the composition PDF method requires a larger number of iterations to reach steady-state. It is recommended that you use the default of 50 **Iterations in Average** until the steady-state solution is obtained. Then, to gradually decrease the residuals, increase the **Iterations in Average** by setting a **Iteration Increment** to a value from 0 to 1 (the value 0.2 is recommended). Subsequent iterations will increase the **Iterations in Average** by the **Iteration Increment**.

For additional information, see the following sections:

18.6.1. Running Unsteady Composition PDF Transport Simulations
18.6.2. Running Compressible Lagrangian PDF Transport Simulations
18.6.3. Running Lagrangian PDF Transport Simulations with Conjugate Heat Transfer

18.6.1. Running Unsteady Composition PDF Transport Simulations

For unsteady Lagrangian composition PDF transport simulations, a fractional step scheme is employed where the PDF particles are advanced over the time step, and then the flow is advanced over the time step. Unlike steady-state simulations, composition statistics are not averaged over iterations, and to reduce statistical error you should increase the number of particles per cell in the **Solution Monitors** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For low speed flows, the thermo-chemistry couples to the flow through density. Statistical errors in the calculation of density may cause convergence difficulties between time step iterations. If you experience this, increase the number of PDF particles per cell, or decrease the density under-relaxation.

18.6.2. Running Compressible Lagrangian PDF Transport Simulations

Compressibility is included when **ideal-gas** is selected as the density method in the Create/Edit Materials Dialog Box (p. 2302). For such flows, particle internal energy is increased by $p\Delta v$ over the time step Δt, where p is the cell pressure and Δv is the change in the particle specific volume over the time step.

18.6.3. Running Lagrangian PDF Transport Simulations with Conjugate Heat Transfer

When solid zones are present in the simulation, ANSYS Fluent solves the energy equation in the turbulent flow zones by the Lagrangian Monte Carlo particle method, and the energy equation in the solid zones by the finite-volume method.

18.7. Postprocessing for Lagrangian PDF Transport Calculations

For additional information, see the following sections:

18.7.1. Reporting Options
18.7.2. Particle Tracking Options

18.7.1. Reporting Options

ANSYS Fluent provides several reporting options for the Lagrangian composition PDF transport calculations. You can generate graphical plots or alphanumeric reports of the following items:

- **Static Temperature**
- **Mean Static Temperature**
- **RMSE Static Temperature**
- **Mass fraction of species-n**
- **Mean species-n Mass Fraction**
- **RMS species-n Mass Fraction**

The instantaneous composition (**Static Temperature** and **Mass fraction of species-n**) in a cell are calculated as,

$$\phi_{instant} = \frac{\sum_{i=1}^{N_c} \phi_p m_p}{\sum_{i=1}^{N_c} m_p} \tag{18.1}$$

where

$\phi_{instant}$ = instantaneous cell species mass fraction or temperature at the present iteration

N_c = number of particles in the cell

ϕ_p = particle mass fraction or temperature

m_p = particle mass

Mean and root-mean-square-error (RMSE) temperatures are calculated in ANSYS Fluent by averaging instantaneous temperatures over a user-specified number of previous iterations (see Monitoring the Solution (p. 1121)).

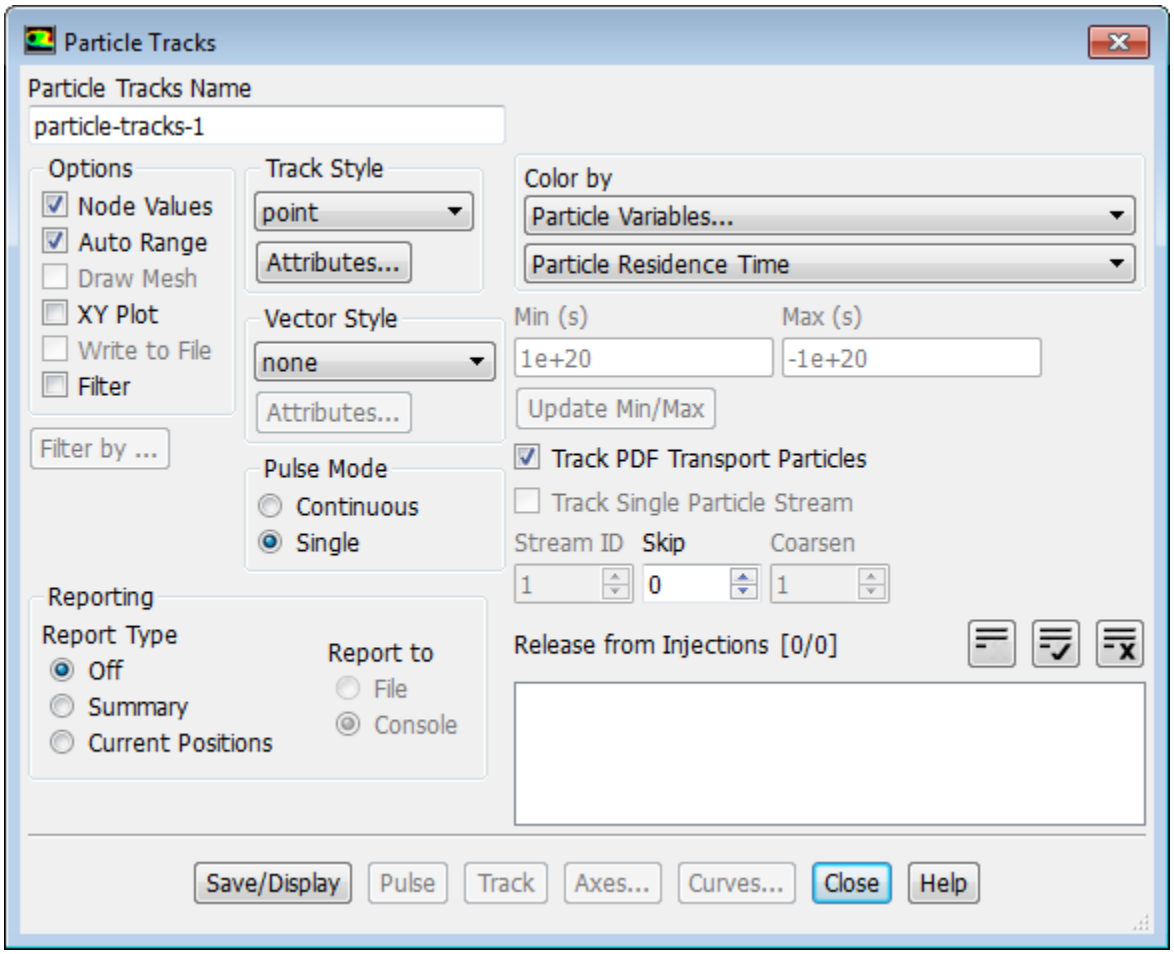
Note that for steady-state simulations, instantaneous temperatures and species represent a Monte Carlo realization and are as such unphysical. Mean and RMSE quantities are much more useful.

18.7.2. Particle Tracking Options

When you have enabled the Lagrangian composition PDF transport model, you can display the trajectories of the PDF particles using the Particle Tracks Dialog Box (p. 2761) (Figure 18.7: The Particle Tracks Dialog Box for Tracking PDF Particles (p. 1124)).

Results → Graphics → Particle Tracks → New...

Figure 18.7: The Particle Tracks Dialog Box for Tracking PDF Particles



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select the **Track PDF Transport Particles** option to enable PDF particle tracking. To speed up the plotting process, you can specify a value n for **Skip**, which will plot only every n^{th} particle. For details about setting other parameters in the **Particle Tracks** dialog box, see Displaying of Trajectories (p. 1330).

When you have finished setting parameters, click **Display** to display the particle trajectories in the graphics window.

18.8. Postprocessing for Eulerian PDF Transport Calculations

For additional information, see the following sections:
18.8.1. Reporting Options

18.8.1. Reporting Options

To postprocess the Eulerian composition PDF transport model, the following variables are available for each mode:

- **Mixture fraction**
- **Mass fraction of species in mode n**
- **Temperature of mode n**
- **Sensible Enthalpy of mode n**

of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 19: Using Chemistry Acceleration

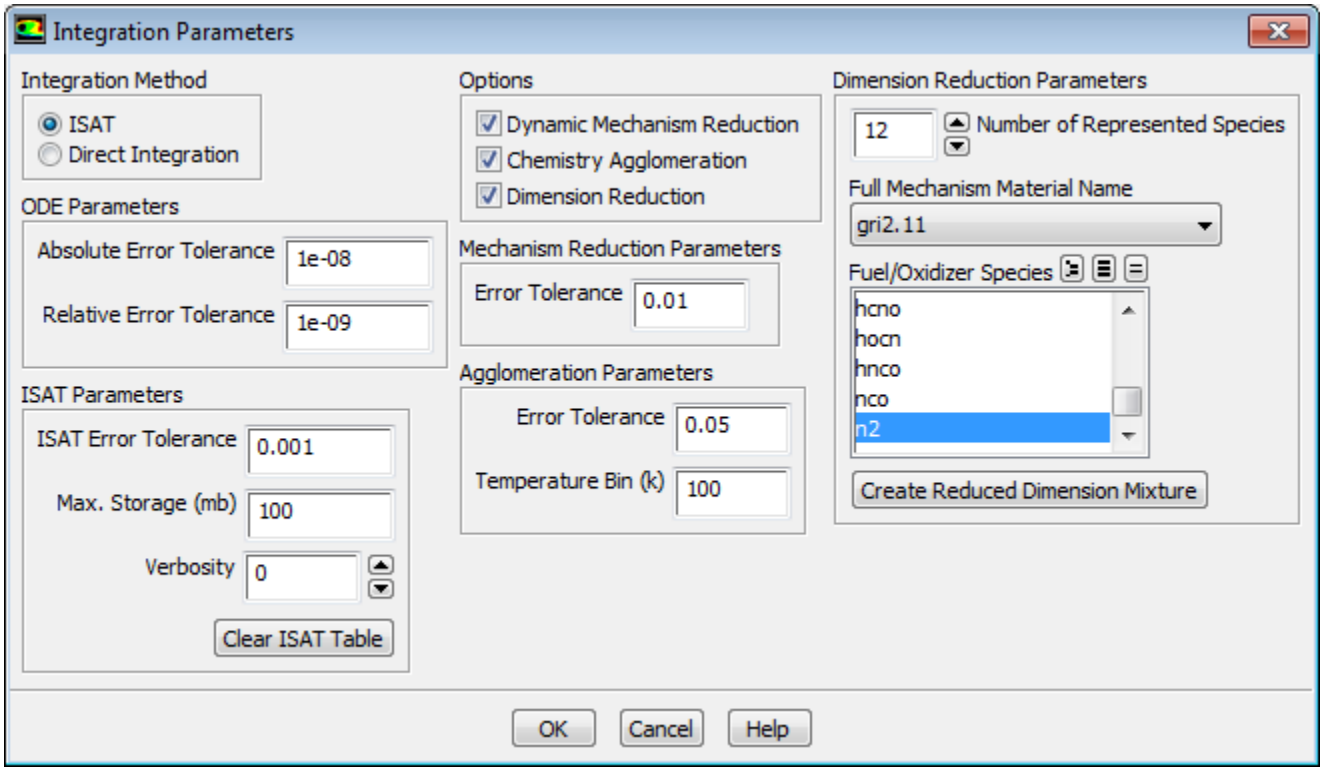
ANSYS Fluent can model detailed chemical kinetics in laminar and turbulent flames. Laminar flames are modeled with the **Laminar Finite-Rate** option, while four turbulence-chemistry interaction models are available for turbulent flames (**Laminar Finite-Rate**, **Eddy-Dissipation Concept**, **Lagrangian PDF Transport**, and **Eulerian PDF Transport**). Detailed chemical mechanisms are invariably numerically stiff and compute-intensive. ANSYS Fluent provides following methods to accelerate these computations:

- ISAT
- Dynamic Mechanism Reduction (DMR)
- Chemistry Agglomeration
- Dimension Reduction
- Dynamic Cell Clustering (DCC) (available with the transient ANSYS CHEMKIN-CFD solver)

All of the methods are enabled or disabled in the **Integration Parameters** dialog box, accessed from the **Species Model** dialog box by clicking the **Integration Parameters...** button in the **Reactions** group box:

Setup → Models → Species Edit...

Figure 19.1: The Integration Parameters Dialog Box Displaying Dimension Reduction



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All of the acceleration methods induce some accuracy loss, and the controlling parameters should be carefully adjusted to ensure that this inaccuracy is acceptable, see Chemistry Acceleration in the *Fluent Theory Guide*. In most cases, applying ISAT and Dynamic Mechanism Reduction (DMR) together should give the best performance. Further information about using the chemistry acceleration models is presented in the following sections:

19.1. Using ISAT
19.2. Using Dynamic Mechanism Reduction
19.3. Using Chemistry Agglomeration
19.4. Dimension Reduction
19.5. Using Dynamic Cell Clustering

19.1. Using ISAT

In-Situ Adaptive Tabulation (ISAT) is a storage-retrieval method that constructs a chemistry table at run time (in-situ) with a user-specified interpolation accuracy (adaptive tabulation). ISAT can be used with all Chemistry solvers except the **None - Explicit Source** solver option.

For ODE solvers (Stiff Chemistry and CHEMKIN-CFD), ANSYS Fluent uses two error tolerances (under **ODE Parameters**):

- **Absolute Error Tolerance**: by default, set to 10^{-8}.
- **Relative Error Tolerance**: by default, set to 10^{-9} for the Stiff Chemistry solver and 10^{-4} for the CHEMKIN-CFD solver.

The default values should be sufficient for most applications, although these tolerances may need to be decreased for some cases such as ignition. For problems in which the accuracy of the chemistry integrations is crucial, it may be useful to test the accuracy of the error tolerances in simple zero-dimensional and one-dimensional test simulations with parameters comparable to those in the full simulation.

If you want to use chemistry agglomeration together with ISAT, enable **Chemistry Agglomeration** in the **Integration Parameters** dialog box and specify the chemistry agglomeration **Error Tolerance** (ε_{tol}). More information can be found in Using Chemistry Agglomeration (p. 1136).

For additional information, see the following sections:

19.1.1. ISAT Parameters
19.1.2. Monitoring ISAT
19.1.3. Using ISAT Efficiently
19.1.4. Reading and Writing ISAT Tables

19.1.1. ISAT Parameters

If you have selected **ISAT** under **Integration Method**, you will then be able to set additional ISAT parameters. The numerical error in the ISAT table is controlled by the **ISAT Error Tolerance** under **ISAT Parameters**. The default **ISAT Error Tolerance** of 0.001 may be sufficiently accurate for temperature and major species, but will most likely need to be decreased to get accurate minor species and pollutant predictions. For steady-state simulations, it may help to start with a high error tolerance during the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

initial iterations towards a converged solution. A larger error tolerance results in smaller tables and quicker run times, but greater error.

Important

After your steady simulation is converged, you should always decrease the **ISAT Error Tolerance** and perform further iterations until the species that you are interested in are unchanged.

The **Max. Storage** is the maximum RAM used by the ISAT table, and has a default value of 100 MB. Generally, you do not need to set it to a value larger than 500 MB. The value of **Verbosity** allows you to monitor ISAT performance in different levels of detail. See Monitoring ISAT (p. 1129) for details about this parameter.

To purge the ISAT table, click the **Clear ISAT Table** button. See Using ISAT Efficiently (p. 1130) for more details.

19.1.2. Monitoring ISAT

You can monitor ISAT performance by setting the **Verbosity** in the **Integration Parameters** dialog box. For a **Verbosity** of 1 or 2, ANSYS Fluent writes the following information periodically to a file named `case-file-name_stats.out`:

- total number of *queries*
- total number of queries resulting in *retrieves*
- total number of queries resulting in *grows*
- total number of queries resulting in *adds*
- total number of queries resulting in *direct integrations*
- cumulative CPU seconds in ISAT
- cumulative CPU seconds outside ISAT
- cumulative wall-clock time in seconds (that is, total CPU time in ISAT plus total CPU time out of ISAT plus CPU idle time)

The ISAT **Verbosity** option of 2 is for expert users who are familiar with ISATAB v5.0 [88] (p. 2891). ANSYS Fluent writes out the following files for **Verbosity** = 2:

- `tablename_stats.out`, as described above
- `tablename_ODE_accuracy.out` reports the accuracy of the ODE integrations. For every new ISAT table entry, if the maximum absolute error in temperature or species is greater than any previous error, a line is written to this file. This line consists of the total number of ODE integrations performed up to this time, the maximum absolute species error, the absolute temperature error, the initial temperature and the time step.
- `tablename_ODE_diagnostic.out` prints diagnostics from the ODE solver
- `tablename_ODE_warning.out` prints warnings from the ODE solver

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Initially, the table name is equal by default to the current case name, and is changed as the table is written or read.

In parallel, each processor builds its own ISAT table. If **Verbosity** is enabled in parallel, each compute node writes out the **Verbosity** file(s) with the node ID number appended to the file name.

19.1.3. Using ISAT Efficiently

Efficient use of ISAT requires thoughtful control. What follows are some detailed recommendations concerning the achievement of this goal.

Important

- The numerical error in the ISAT table is controlled by the **ISAT Error Tolerance**, which has a default value of 0.001. This value is relatively large, which allows faster convergence times for steady-state simulations. However, once the solution has converged, it is important to reduce this **ISAT Error Tolerance** and re-converge. This process should be repeated until the species that you are interested in modeling are unchanged. Unsteady simulations should be run with a sufficiently small **ISAT Error Tolerance** so that the species of interest are unaffected by this parameter. Note that as the error tolerance is decreased, the memory and time requirements to build the ISAT table will increase substantially. There is a large performance penalty in specifying an error tolerance smaller than is needed to achieve acceptable accuracy, and the error tolerance should be decreased gradually and judiciously.
- As described in Mesh Partitioning and Load Balancing (p. 2030), you can select portions of the simulation to consider when performing dynamic load balancing in multiprocessor simulations. If the **ISAT** option is selected in the **Weighting** tab of the Partitioning and Load Balancing Dialog Box (p. 2767), the time required for solving chemistry will be factored in when assigning the computational cells to each available processor. It is recommended that you select this option when solving stiff chemistry, particularly when the Dynamic Mechanism Reduction method is enabled; thus, more resources can be allocated for the cells with the larger mechanisms.

During the initial iterations, before a steady-state solution is attained, transient composition states occur that are not present in the steady-state solution. For example, you might patch a high temperature region in a cold fuel-air mixing zone to ignite the flame, whereas the converged solution never has hot reactants without products. Since all states that are realized in the simulation are tabulated in ISAT, these initial mappings are wasteful of memory, and can degrade ISAT performance. If the table fills the allocated memory and contains entries from an initial transient that are no longer accessed, it may be beneficial to purge the ISAT table. This is achieved by either clearing it in the **Integration Parameters** dialog box, or saving your case and data files, exiting ANSYS Fluent, then restarting ANSYS Fluent and reading in the case and data. This can also be done with the TUI command `define/models/species/clear-isat-table`.

From experience, ISAT performs very well on premixed turbulent flames, where the range of composition states are smaller than in non-premixed flames. ISAT performance degrades in flames with large residence times, where more work is required in the ODE integrator.

19.1.4. Reading and Writing ISAT Tables

ANSYS Fluent can write and subsequently read ISAT tables. However, it is in general not recommended to write and read ISAT tables for the following reason: ISAT tabulates chemical states that are specific

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

to a single simulation. The ISAT tabulated composition states are determined by the geometry, boundary conditions, physics models such as turbulence and radiation, thermodynamic and transport properties, as well the chemical mechanism. If any of these parameters change, the realized composition space changes, and significant parts of the existing ISAT table are no longer accessed. These un-accessed ISAT table entries slow interpolation and decrease the number of useful accessed table entries that can be added. Since the time consumed building the ISAT table is typically much smaller than simulation run times, it is advised to rebuild the table when restarting.

When ANSYS Fluent is run in parallel, each partition builds its own ISAT table and does not exchange information with ISAT tables on other compute nodes. You can save the ISAT tables on all compute nodes:

File → Write → ISAT Table...

Each compute node writes out its ISAT table to the specified file name, with the node ID number appended to the file name. For example, a specified file name of `my_name` on a two compute node run will write two files called `my_name-0.isat` and `my_name-1.isat`.

Subsequent runs can start from existing ISAT tables by reading them into memory.

File → Read → ISAT Table...

Files can be read in two ways:

- Parallel nodes can read in corresponding ISAT tables saved from a previous parallel simulation. The appended node ID should not be removed from the input file name.

  Note

  The ability to use ISAT tables generated from a parallel simulation with a different number of parallel nodes is not supported.

- All nodes can read one unique ISAT table. You might use this approach if you have a large table from a serial simulation. ANSYS Fluent first checks to see if the exact file name that you specified exists, and if it does, all nodes will read this one file.

19.2. Using Dynamic Mechanism Reduction

Computational time increases with the size of the chemical kinetics mechanism used in the simulation. Dynamic Mechanism Reduction (DMR) decreases the mechanism size at each cell (or particle) to include only those species and reactions necessary for accurate modeling (within defined tolerances) of the chemical kinetics at the local conditions. This is performed at every flow iteration (for steady simulations) or time step (for transient simulations). Because the mechanism is only required to be accurate at the local conditions, smaller reduced mechanisms can be used with less accuracy loss than when using skeletal mechanism reduction, where a single reduced mechanism is used throughout the simulation. The speed-up from this approach is problem-dependent, but on average is about a factor of two or more compared to a case with no chemistry acceleration.

For an even greater increase in performance, you can use Dynamic Mechanism Reduction with any combination of the other chemistry acceleration options available in ANSYS Fluent. In most cases, applying ISAT and DMR together should give the best performance. Note, however, that ISAT performance

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

degrades when accuracy requirements are very strict or when conditions are not revisited often in a simulation. An example is unsteady ignition simulations, where ISAT table entries may not be re-used. However, the important species and reactions can vary widely during the simulation; for example, many of the low temperature ignition reactions are only required for the small spark zone and short spark duration. In such situations, you may achieve better performance using Dynamic Mechanism Reduction along with direct integration method rather than ISAT.

Combining multiple chemistry acceleration methods, however, compounds accuracy loss, since each of these methods accelerates the simulation by sacrificing some accuracy. In general, greater speed-up is achievable when the full mechanism is larger, because there is potential for a greater degree of reduction.

Important

When using Dynamic Mechanism Reduction along with ISAT, setting the error tolerance for either approach above its default value degrades accuracy faster than when either method is used alone.

Dynamic Mechanism Reduction is performed using the Directed Relation Graph (DRG) algorithm. For details of the DMR algorithm, refer to the discussion in Dynamic Mechanism Reduction in the *Fluent Theory Guide*.

You can enable Dynamic Mechanism Reduction through either the graphical user interface (GUI) or the text user interface (TUI) as follows.

- In the GUI, enable the **Dynamic Mechanism Reduction** option in the **Integration Parameters** dialog box.
- In the TUI, enter the following text command in the console:

  ```
  define/models/species/integration-parameters
  ```

  When prompted with `Enable Dynamic Mechanism Reduction?`, answer with `yes`.

  Note that it is not necessary to enable Chemistry Acceleration Expert mode in order to use Dynamic Mechanism Reduction.

For additional information, see the following sections:
19.2.1. Mechanism Reduction Parameters
19.2.2. Monitoring and Postprocessing Dynamic Mechanism Reduction
19.2.3. Using Dynamic Mechanism Reduction Effectively

19.2.1. Mechanism Reduction Parameters

In ANSYS Fluent, Dynamic Mechanism Reduction is controlled by the error tolerance and the target species list, as described below.

Error Tolerance

(ε in Equation 12.4 in the *Fluent Theory Guide*).The default value for error tolerance ε is `0.01`, which should work well for most simulations, balancing speed and accuracy. However, a larger tolerance may be sufficient for some simulations (for example, steady-state simulations with moderate accuracy requirements), while a smaller tolerance may be required in other cases with stricter accuracy requirements (for example, modeling auto-ignition delay times for a highly complex fuel). In general, a larger tolerance yields faster, but less accurate simulations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The error tolerance can be adjusted through the GUI or TUI as follows:

- In the GUI, set **Error Tolerance** to the desired value in the **Mechanism Reduction Parameters** group box in the **Integration Parameters** dialog box.
- In the TUI, enter the following text command: `define/models/species/integration-parameters`. When prompted with `Mechanism Reduction Error Tolerance`, enter the desired tolerance (a positive, nonzero value) or press **Enter** to retain the default value.

Note

- In the TUI, you can also enable Chemistry Acceleration Expert mode, other chemistry acceleration methods, and specify ODE integrator parameters (see Using ISAT (p. 1128) for details about these parameters).
- Chemistry Acceleration Expert mode should only be enabled if you want to modify the default target species list.

Target Species List

As described in the Dynamic Mechanism Reduction in the *Fluent Theory Guide*, the target species are those species that you want to predict most accurately. The default number of target species N_{target} is 3. The first default target species is hydrogen radical. DRG will add two other species with the largest mass fractions to complete the target species list at each flow time step or iteration. DRG will then identify all other species that must also be included in the mechanism in order to accurately model these targets.

Although you should rarely need to alter the default target species list, ANSYS Fluent provides an option to specify target species of your choice. The designated target species can be specified only in the TUI when Chemistry Acceleration Expert mode is enabled. Enter the text command `define/models/species/integration-parameters` and then answer `yes` when prompted with `Enable Chemistry Acceleration expert?`.

ANSYS Fluent provides the ability to explicitly specify target species. From your mixture material list, you can select any number N_{user} of target species to be included in the kinetics mechanism. In case no targets were selected (N_{user}=0) or the number of user-selected targets N_{user} is less than the minimum number of target species N_{target} (N_{user}<N_{targets}), the DRG algorithm will add the (N_{targets}−N_{user}) species with the largest mass fractions to the target species list.

As discussed in the Dynamic Mechanism Reduction in the *Fluent Theory Guide*, there is an option to remove a species from the target list whenever its mass fraction is below a specified threshold. This option is disabled by default in ANSYS Fluent (that is, the default value for minimum mass fraction is 0).

When specifying Target Species List, you will receive the following prompts in the console:

1. `Minimum number of target species [3]`

   Enter the desired number of targets.

2. `Minimum mass fraction of target species [0]`

   Enter minimum allowable target mass fraction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The current target species list will be displayed in the console window (for example, the console output for the default target species consisting of hydrogen radical will be `Current target species list = (h)`).

3. `Enter target species list...`

   `Species name [""]`

   Enter target species name, for example, **"ch4"**.

   Important

   You *must* enter the complete name of the species as it appears in the **Chemical Formula** field in the **Create/Edit Materials** dialog box within quotes (" ").

   After you enter the first target species, you will be prompted to specify the second one, and so on, until you press **Enter** to complete the setup.

   Note, that if you have entered **0** for the minimum number of target species N_{target} and have not provided any target species (that is, the number of user-selected targets, N_{user}, is zero), ANSYS Fluent will automatically select the three species with the largest mass fraction and use them as the target species in the DRG algorithm.

19.2.2. Monitoring and Postprocessing Dynamic Mechanism Reduction

When Chemistry Acceleration expert is enabled in the TUI, two additional field variables are available to be monitored or examined in postprocessing:

- **DRG Reduced Number of Species** in the **Species...** category
- **DRG Reduced Number of Reactions** in the **Reactions...** category

These field variables quantify the size of the reduced mechanism at each cell or particle in the domain (the number of retained species and reactions, respectively).

When you use DMR in combination with ISAT, ANSYS Fluent will report values of zero for **DRG Reduced Number of Species** and **DRG Reduced Number of Reactions** for those cells where the ANSYS solver computed the solution using table lookup instead of direct integration in the ISAT algorithm. A cell value of zero **DRG Reduced Number of Species** does not imply that the DMR algorithm eliminated all species from the mechanism; rather, it indicates that the ANSYS solver performed ISAT table lookup to obtain the chemistry solution at the cell.

If you want to view the cells for which ISAT table lookup was performed in the last iteration or time step, display the **DRG Reduced Number of Species** plot clipped to a range of 0 to 0. (Make sure that the **Node Value** option is deselected in the postprocessing dialog boxes.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you want to view the cells for which DMR was performed in the last iteration or time step, display the **DRG Reduced Number of Species** plot clipped to a range of 1 to a global maximum value (as it appears in the **Max** field when **Global Range** is selected in the postprocessing dialog boxes).

Note

The DMR postprocessing field variables are not stored in the data file and, hence, will not be available for postprocessing in the next session. If you want to postprocess these variables in your next session, read the data file and perform a single iteration or time step (for steady-state or transient simulations, respectively) in order for the DMR data to be calculated and available for viewing.

19.2.3. Using Dynamic Mechanism Reduction Effectively

As described in Dynamic Mechanism Reduction in the *Fluent Theory Guide*, mechanism reduction is performed at each cell or particle, once per time step (for transient simulations) or per flow iteration (for steady-state simulations). It is assumed that the reduced mechanism created for the starting conditions will remain valid for the entire transport time step over which the chemistry ODE is integrated. If the chemistry integration time interval is very large, the chemical state can change significantly, degrading the accuracy of the reduced mechanism. In some cases (particularly transient simulations such as ignition) it may be necessary to enforce smaller flow time steps in order to effectively use Dynamic Mechanism Reduction. In this way the reduced mechanisms are updated more frequently to match the changing chemical states.

Note that Dynamic Mechanism Reduction works best when there are significant regions in a computational domain and/or times during a simulation with relatively low chemical activity (for example, low temperature, low mixing of fuel/oxidizer, low concentrations of reactive species, and so on). Consider a simple opposed flow diffusion flame problem with pure fuel as one stream and pure oxygen as the other stream. Large mechanisms (which, depending on the error tolerance, may be close to the full mechanism size) will likely be used in the mixing region where the flame is located, while smaller mechanisms would be used elsewhere in the domain. You should not expect much speed-up if a very large fraction of your grid cells (for example, 90%) are in the flame region.

In steady-state simulations, you can improve the solution time by first running to convergence with a larger error tolerance ε, and then restarting the simulation repeatedly, gradually decreasing the error tolerance ε until you reach the desired accuracy level. For example, if you first converge the solution with the error tolerance ε=0.1, then iterate the solution further to convergence with the lower error tolerance, ε=0.05, and then with the desired error tolerance ε=0.01, you will generally be able to achieve faster convergence than iterating from initial conditions with the error tolerance ε=0.01.

Important

As described in Mesh Partitioning and Load Balancing (p. 2030), you can select portions of the simulation to consider when performing dynamic load balancing in multiprocessor simulations. When using the Dynamic Mechanism Reduction along with ISAT, it is recommended that you select the **ISAT** option in the **Weighting** tab of the Partitioning and Load Balancing Dialog Box (p. 2767) when solving stiff chemistry. If **ISAT** is selected, the time required for solving chemistry will be factored in when assigning the computational cells to each available processor; thus, more resources can be allocated for the cells with the larger mechanisms.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

19.3. Using Chemistry Agglomeration

The Chemistry Agglomeration method reduces the number of calls to the computationally expensive ODE integrator by clustering cells with similar compositions. The size of these clusters is determined by the agglomeration parameters **Error Tolerance** (ε_{tol}) and **Temperature Bin** (Δ_T) in the **Integration Parameters** dialog box. Larger values of ε_{tol} and Δ_T result in a larger number of agglomerated cells, fewer calls to the reaction integrator, increased run-time speed, but greater error.

You can also set the chemistry agglomeration parameters using the text user interface (TUI) command `define/models/species/integration-parameters`. Once you enable agglomeration chemistry, ANSYS Fluent prompts you for `Agglomerate Chemistry Error Tolerance` and `Agglomerate Chemistry Temperature Bin`. Enter the desired values or press **Enter** to retain the default values of `0.02` for `Agglomerate Chemistry Error Tolerance` and `10` for `Agglomerate Chemistry Temperature Bin`.

More information can be found in Chemistry Agglomeration in the *Fluent Theory Guide*.

Important

The solution accuracy can be improved by decreasing the tolerances. Generally, it should not be necessary to reduce the tolerances below 0.01 and 10 K.

19.4. Dimension Reduction

Detailed kinetic mechanisms typically contain a multitude of intermediate species that far exceed the number of major fuel, oxidizer, and product species. Chemical mechanism **Dimension Reduction** reduces the number of intermediate species transport equations (called representative species) that are solved, and reconstructs the 'unrepresented' species using chemical equilibrium assumptions.

Important

Since ANSYS Fluent is limited to a maximum of 700 transported species, the main use of **Dimension Reduction** is to enable simulation with chemical mechanisms containing more than 700 species.

Follow these steps to use **Dimension Reduction**:

- Import your CHEMKIN mechanism. Note that you can import CHEMKIN mechanisms that contain more than 700 species.
- Click the **Integration Parameters** button in the **Species Model** dialog box, and enable **Dimension Reduction**.
- Set the **Number of Represented Species**. This must be greater than 10 and less than the number of species in the full mechanism. The **Number of Represented Species** must also be less than 700 minus the number of unrepresented elements (the number of chemical elements in the unrepresented species). A larger **Number of Represented Species** will increase accuracy, but also increase computational expense. The default of 12 has been chosen to provide a good compromise between accuracy and speed.
- Select the **Full Mechanism Material Name**, which is typically the name of the CHEMKIN mechanism that you imported. ANSYS Fluent can store several imported CHEMKIN mechanisms in different mixture materials

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

whose mechanisms you are not using. However, since mechanisms are typically large, you should delete unused mixtures to reduce memory requirements.

- Set the boundary and initial fuel and oxidizer, as well as product species, as represented species. These are set in the **Fuel/Oxidizer Species** list. Note that you can force other species to be represented by selecting them here. Species of interest, especially species that are not near chemical equilibrium, such as pollutants, and their associated intermediate species in the mechanism should also be included. Intermediate species that occur in large mass fractions relative to the fuel and oxidizer species should be included, as well as species important in the chemical pathway. For example, for methane combustion in air, CH_3 should be included as a represented species since CH_4 pyrolizes to CH_3 first.

- Click **Calculate Reduced Dimension Mixture**. This will create a new mixture material called `reduced-dimension-mixture`, which contains the represented species as well as proxy 'species' for the unrepresented elements. These unrepresented elements have "u" prepended to the element name. You should never rename the reduced-dimension-mixture mixture material, or select another mixture as the active material, while **Dimension Reduction** is enabled.

- Continue with the setup, solution, and postprocessing as for other detailed chemistry cases. Note that the boundary and initial mass fraction of unrepresented elements should always be zero. The entries for the unrepresented element mass fractions are disabled in the ANSYS Fluent GUI.

For postprocessing, the unrepresented elements are available in the **Species** list as the element name with "u" prepended. All species in the full mechanism, consisting of both represented and unrepresented species, are available in the **Full Mechanism Species...** category of the postprocessing dialog boxes.

After you obtain a preliminary solution with **Dimension Reduction**, it is recommended that you check the magnitude of all unrepresented species, which are available in the **Full Mechanism Species...** option in the **Contours** dialog box. If the mass fraction of any unrepresented species is larger than other represented species, you should repeat the simulation with this species included in the represented species list. In turn, the mass fraction of all unrepresented elements should decrease.

Note

Note that **Dimension Reduction** is only available with ISAT. **Dimension Reduction** is initially comparable in speed to a simulation with the full mechanism, but iterations become significantly faster at later times when the ISAT table is populated.

For information about the theory of this option, see Chemical Mechanism Dimension Reduction in the *Fluent Theory Guide*.

19.5. Using Dynamic Cell Clustering

The Dynamic Cell Clustering (DCC) method is available with the transient ANSYS CHEMKIN-CFD solver. DCC groups computational cells with similar temperatures, pressures, and initial species mass fractions into clusters.

Two parameters are available for controlling cell clustering:

- **Max. Temperature Dispersion** (default =10 K)
- **Max. Equiv. Ratio Dispersion** (default =0.05)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The default values for these parameters have been shown to provide accurate results for a wide range of combustion cases. Reducing these criteria will generally result in more clusters being created, and therefore more computational time.

The method is enabled by default and is strongly recommended for improving computational efficiency. For background information about DCC, refer to Dynamic Cell Clustering with ANSYS CHEMKIN-CFD Solver in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 20: Modeling Engine Ignition

This chapter discusses how to use the engine ignition models available in ANSYS Fluent in the following sections. For information about the theory behind these ignition models, see Engine Ignition in the Theory Guide.

20.1. Spark Model
20.2. Autoignition Models
20.3. Crevice Model

20.1. Spark Model

The spark model in ANSYS Fluent will be described in the context of the premixed turbulent combustion model. For information regarding the theory of this model, see Spark Model in the Theory Guide. Information regarding the use of this model is detailed in the following sections:

20.1.1. Using the Spark Model
20.1.2. Using the ECFM Spark Model

20.1.1. Using the Spark Model

You can model a single spark or multiple sparks. To use the spark model, perform the following steps:

1. Select **Transient** from the **Time** list in the **General** task page (or from the **General** → **Analysis Type** in the tree).

2. In the **Species Model** dialog box, select one of the following reaction models:

   Setup → **Models** → **Species** **Edit...**

   - Under **Model**, select **Species Transport**, and under **Reactions**, enable **Volumetric**.
   - Under **Model**, select **Premixed Model** with the **C Equation** or **G Equation** model enabled. See Setting Up the C-Equation and G-Equation Models (p. 1092) for more information.

   The **Spark Ignition** model will now appear in the **Models** task page and under the **Models** tree item.

   Important

   When you read in a R14.5 case file, ANSYS Fluent will revert to the R14.5 spark model by default. To switch to the current spark model, you can either

   - open the **Spark Ignition** dialog box, or
   - use the TUI `define/models/species/spark-model` command.

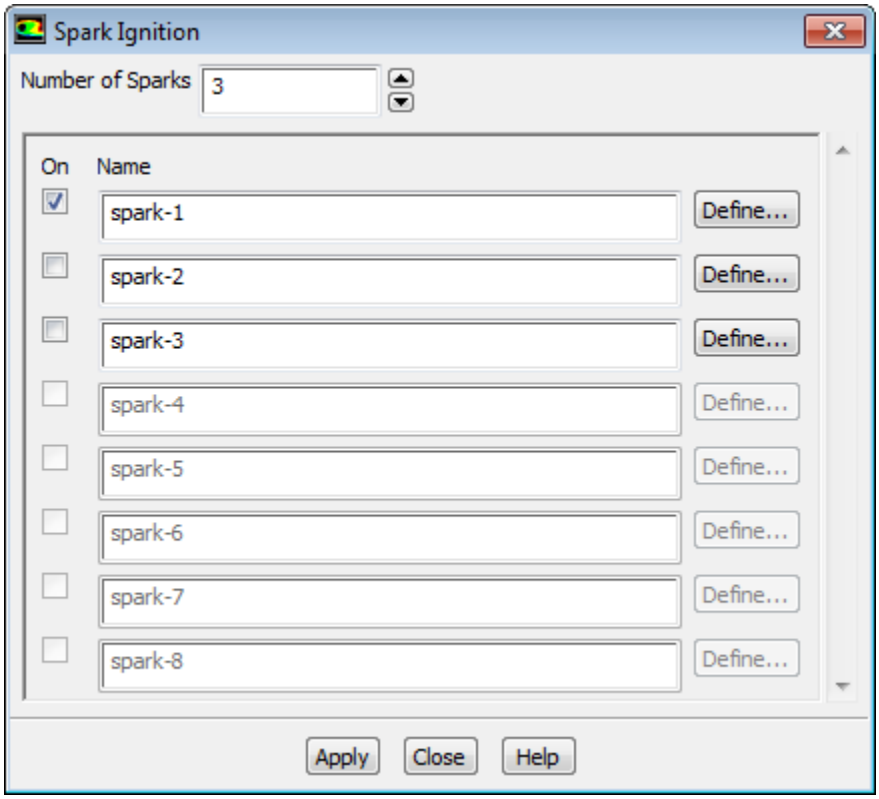
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can also use the TUI `define/models/species/spark-model` command to revert back to the R14.5 spark model.

3. Define sparks for your case using the **Spark Ignition** dialog box (see Figure 20.1: The Spark Ignition Dialog Box (p. 1140)).

   Setup → Models → Species → Spark Ignition Edit...

   Figure 20.1: The Spark Ignition Dialog Box



4. Specify the **Number of Sparks** you would like to include in your simulation. You can define up to 16 sparks.

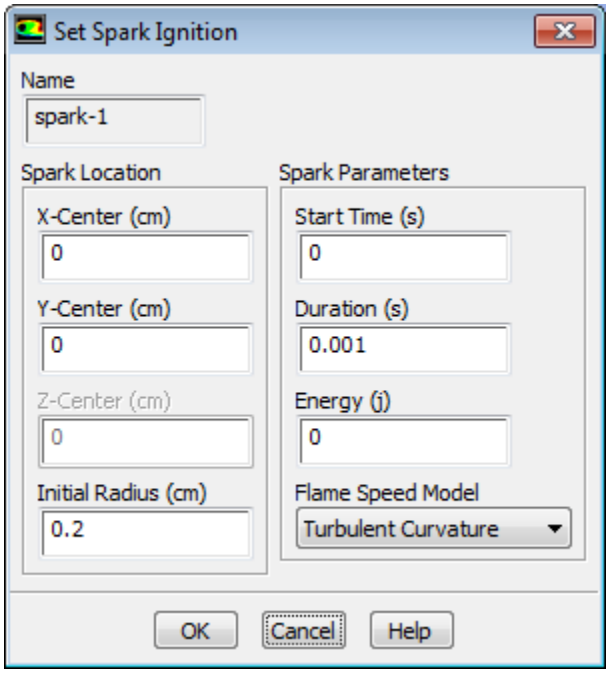
5. While you can define several sparks, you can choose which ones to turn on using the **On** option.

6. Enter the **Name** of the spark, or simply keep the default name.

7. Click the **Define...** button to open the **Set Spark Ignition** dialog box (Figure 20.2: The Set Spark Ignition Dialog Box (p. 1141)), where you will set the parameters of the selected spark ignition models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 20.2: The Set Spark Ignition Dialog Box



8. Set the spark model parameters.

   - Set X, Y, and Z coordinates of the spark center and the **Initial Radius** of the spark kernel in the **Spark Location** group box.
   - Enter **Start Time** and **Duration** in the **Spark Parameters** group box.

     Important

     When the in-cylinder model is turned on, the **Start Time** is entered in crank angle degrees instead of seconds, while the spark **Duration** is still in seconds. The value you enter for **Start Time** is for one complete engine cycle. In subsequent cycles, the spark is enabled according to Equation 10.30 (p. 716), where θ_{event} corresponds to the spark start crank angle.

   - (optional) Set **Energy** to a positive value if you want to model the higher temperature levels within the spark kernel. The energy input will be evenly distributed across the specified spark duration. This energy is not required to initiate combustion. The spark model will control the spark kernel growth and combustion progress. For this reason the default energy input is zero. If you specify extra energy here, it will raise the kernel temperature beyond that given by the combustion process.
   - Select the **Flame Speed Model** from the drop-down list. For details of these models see Spark Model Theory in the *Fluent Theory Guide*.

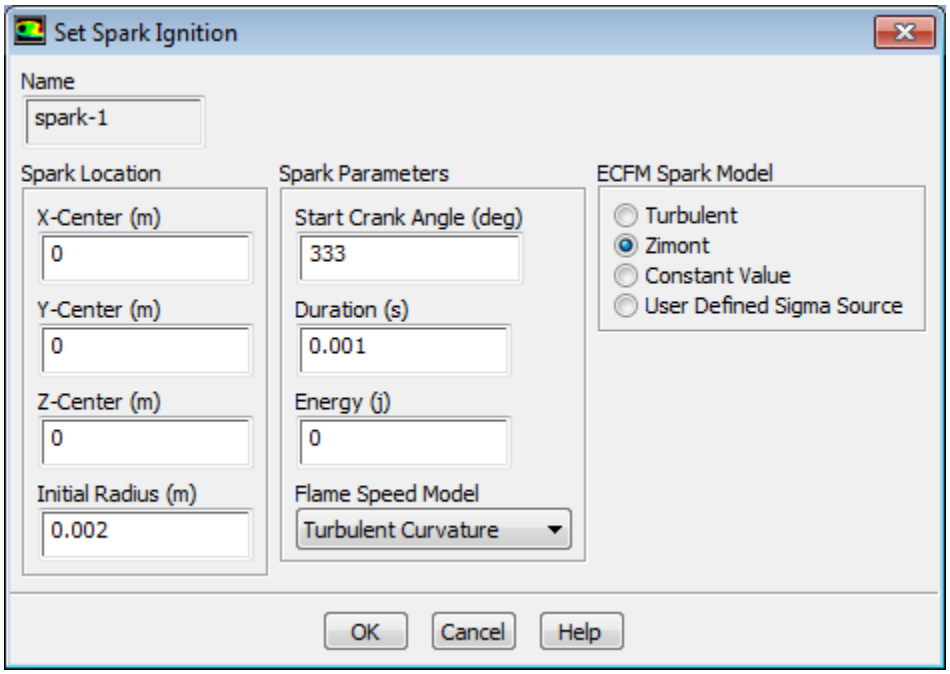
20.1.2. Using the ECFM Spark Model

When the **Extended Coherent Flamelet Model** (see Setting Up the Extended Coherent Flame Model (p. 1094)) is selected in the **Species Model** dialog box, the **Set Spark Ignition** dialog box will exhibit

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

additional **ECFM Spark Model** options, as shown in Figure 20.3: The Set Spark Ignition Dialog Box Displaying the ECFM Spark Model Options (p. 1142).

Figure 20.3: The Set Spark Ignition Dialog Box Displaying the ECFM Spark Model Options



In addition to specifying the variables mentioned in Using the Spark Model (p. 1139), you can select from one of the following ECFM Spark models:

- **Turbulent**
- **Zimont** (default)
- **Constant Value**
- **User Defined Sigma Source**

This controls the way in which the value of the flame surface density is calculated. More details are given in ECFM Spark Model Variants in the *Fluent Theory Guide*.

If you choose **Constant Value** you will be required to specify the value for flame surface density. If you choose **User Defined Sigma Source** you will need to choose the hooked user-defined function to apply a custom source term to the ECFM equation within the volume of the spark ignition kernel. For more detail about this user-defined function, refer to Hooking `DEFINE_ECFM_SPARK_SOURCE` UDFs in the *Fluent Customization Manual*.

20.2. Autoignition Models

Autoignition phenomena in engines are due to the effects of chemical kinetics of the reacting flow inside the cylinder. There are two types of autoignition models considered in ANSYS Fluent:

- knock model in spark-ignited (SI) engines
- ignition delay model in diesel engines

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For information regarding the theory behind autoignition models, see Autoignition Models in the Theory Guide. Using the Autoignition Models (p. 1143) describes how to use the autoignition models in ANSYS Fluent.

20.2.1. Using the Autoignition Models

To use the autoignition model, perform the following steps:

1. Select **Transient** from the **Time** list in the **General** task page (or from the **General** → **Analysis Type** in the tree).

2. Select an appropriate reaction model in the **Species Model** dialog box.

   Setup → **Models** → **Species** **Edit...**

3. The models in the **Species Model** dialog box that are compatible with the autoignition model are **Species Transport**, **Premixed Combustion**, and **Partially Premixed Combustion**.

   The **Autoignition** model will now appear in the **Models** task page and under the **Models** tree item.

   Important

   - If you select **Species Transport**, you must also enable the **Volumetric** option in the **Reactions** group box.
   - The **Premixed Combustion** and **Partially Premixed Combustion** models are only available for turbulent flows using the pressure-based solver.

4. Select the Autoignition model.

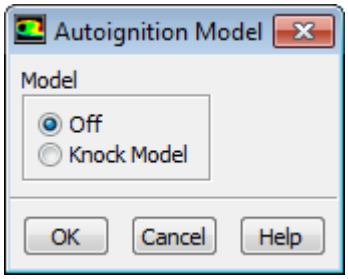
   Setup → **Models** → **Species** → **Autoignition** **Edit...**

   - If **Species Transport** is selected in the **Species Model** dialog box, you can only select the **Ignition Delay Model**.

     Figure 20.4: The Ignition Delay Model in the Autoignition Model Dialog Box

     
   - If **Premixed Combustion** is selected in the **Species Model** dialog box, you can only select the **Knock Model**.

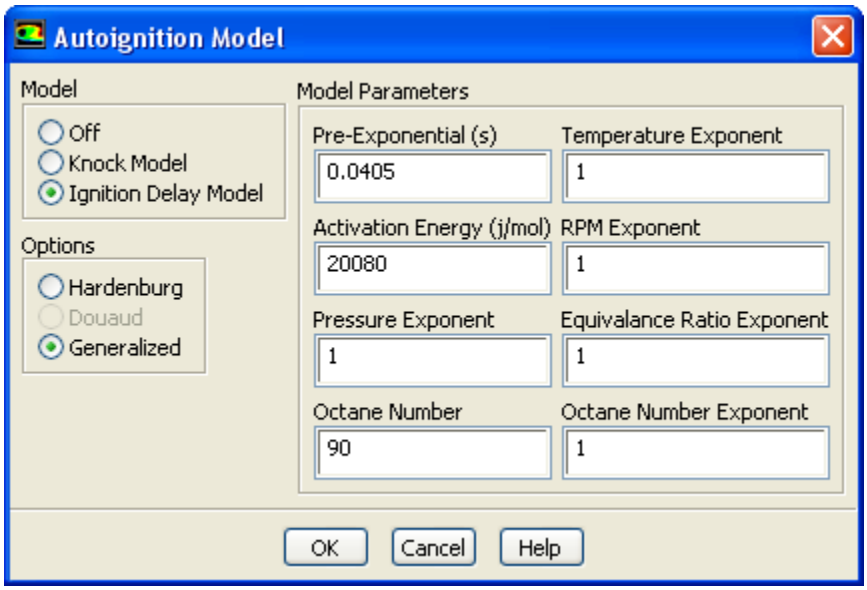
Figure 20.5: The Knock Model in the Autoignition Model Dialog Box



- If **Partially Premixed Combustion** is selected in the **Species Model** dialog box, you can select either the **Knock Model** or the **Ignition Delay Model**.

5. When the **Ignition Delay Model** is enabled, the dialog box expands to include the modeling parameters for this model (Figure 20.6: The Ignition Delay Model for the Partially Premixed Combustion Model (p. 1144)). The two correlation options that exist with this model are **Hardenburg** and **Generalized**. Depending on which correlation option is selected, the appropriate modeling parameters will appear in the dialog box.

Figure 20.6: The Ignition Delay Model for the Partially Premixed Combustion Model



- The **Hardenburg** option is typically used for heavy duty diesel engines. With this option, the following parameters are available:
  - **Pre-Exponential**
  - **Pressure Exponent**
  - **Activation Energy**
  - **Cetane Number**

  For the **Species Transport** model, **Fuel Species** is selected from the drop-down list.

- The **Generalized** option is described by Equation 13.10 in the Theory Guide. With this option, the following parameters are available:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

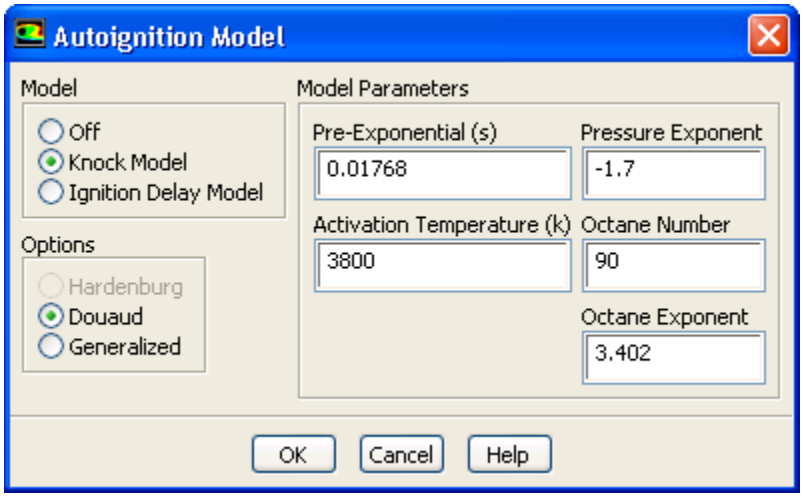
- **Pre-Exponential**
- **Temperature Exponent**
- **Activation Energy**
- **RPM Exponent**
- **Pressure Exponent**
- **Equivalence Ratio Exponent**
- **Octane Number**
- **Octane Number Exponent**

For the **Species Transport** model, **Fuel Species** is selected from the drop-down list.

Default values of these parameters can be found in Default Values of the Variables in the Hardenburg Correlation in the *Fluent Theory Guide*.

6. When the **Knock Model** is enabled, the dialog box expands to include modeling parameters for this model (Figure 20.7: The Knock Model with the Partially Premixed Combustion Model Enabled (p. 1145)). The two correlation options that exist with this model are **Douaud** and **Generalized**. Depending on which correlation option is selected, the appropriate modeling parameters will appear in the dialog box.

Figure 20.7: The Knock Model with the Partially Premixed Combustion Model Enabled



- The **Douaud** option is used for knock in SI engines. The modeling parameters that are specified in the **Autoignition Model** dialog box for this option are the **Pre-Exponential**, **Pressure Exponent**, **Activation Temperature**, **Octane Number**, and **Octane Exponent** (Equation 13.9 in the Theory Guide).
- The **Generalized** option (Equation 13.10 in the Theory Guide) in the knock model requires the same parameters as in the ignition delay model.

20.3. Crevice Model

For information regarding the theory behind the crevice model, see Crevice Model in the Theory Guide. Using the crevice models in ANSYS Fluent are described in the following sections:

20.3.1. Using the Crevice Model

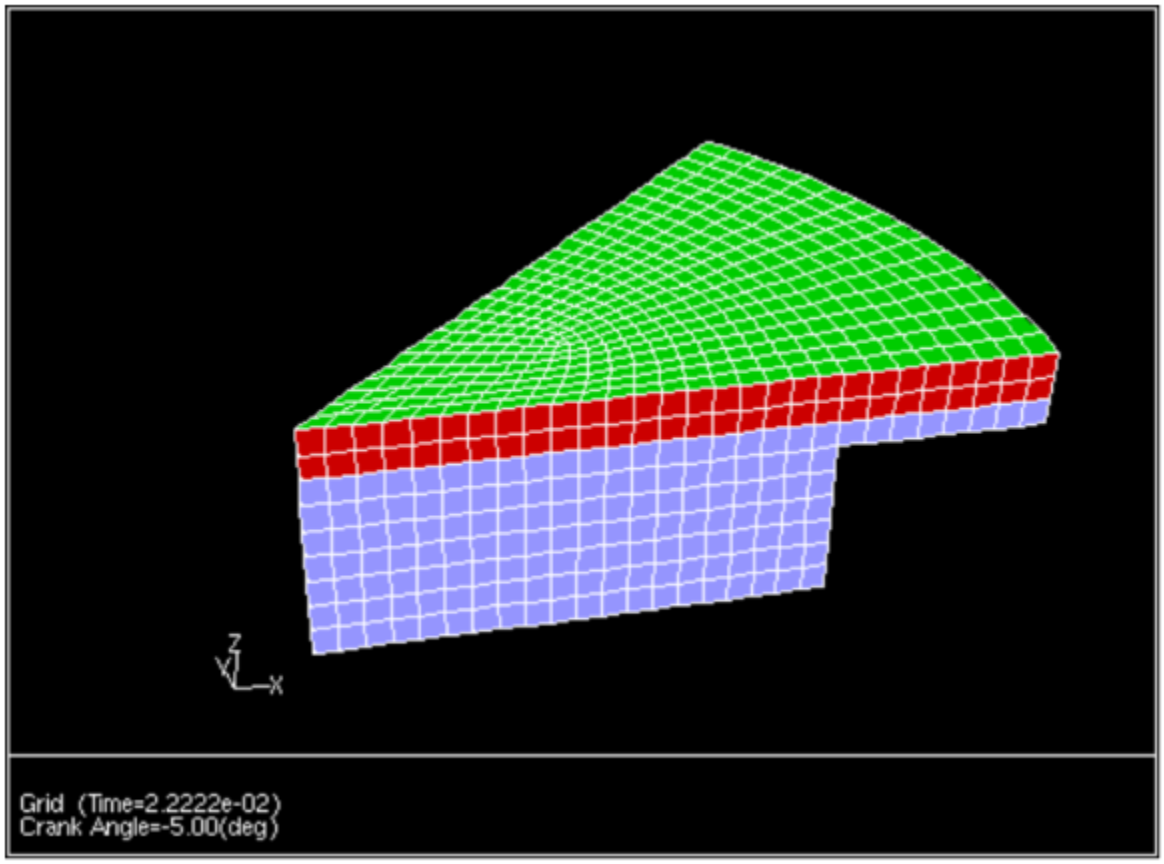
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

20.3.2. Crevice Model Solution Details
20.3.3. Postprocessing for the Crevice Model

20.3.1. Using the Crevice Model

An optical experimental engine [25] (p. 2888) is used below to show a working example of how to use the crevice model as it is implemented in ANSYS Fluent. The mesh at ten crank angle degrees before top center is shown in Figure 20.8: Experimental Engine Mesh (p. 1146).

Figure 20.8: Experimental Engine Mesh



The following example shows the necessary steps to enable the crevice model for a typical in-cylinder flow.

1. From the > prompt, enter the `define/models` menu by using the following text command:

   `define` → `models`

2. Enable the crevice model, as follows:

```
/define/models   crevice-model?

Enable crevice model? [no] yes
/define/models
acoustics/                multiphase/                    species/
addon-module              noniterative-time-advance?     steady?
axisymmetric?             nox?                           unsteady-1st-order?
crevice-model-controls/   radiation/                     unsteady-2nd-order?
crevice-model?            solidification-melting?        viscous/
dpm/                      solver/
energy?                   soot?
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
   frozen-flux?              sox?
```

3. Enter the ring pack geometry:

```
   /define/models   crevice-model-controls

   Cylinder bore (m) [0.1] 0.1397
   Piston to bore clearance (m) [3.0e-5] 5.08e-05
   Piston crevice temperature (K) [400] 433
   Piston sector angle (deg) [360] 45
   Ring discharge coefficient [0.8] 0.7
   Pressure in crankcase (exit pressure) (Pa) [101325]
   Write  out  crevice  data  to  a  file?  [no]   yes

   output file name ["crev.out"]

 Available  wall  threads  are:  (wall.1  wall  wall-8)
 Leaking  wall []   wall.1

Shared boundary [] wall-8
   Selected  boundary  threads  :  (wall.1  wall-8)
  Use  these  zones?  [yes]   yes

Solve crevice model ? [no] yes
Number of rings [3]
           Width  of  ring  number  0  is:  [0.00375]
       Thickness  of  ring  number  0  is:  [0.0015]
         Spacing  of  ring  number  0  is:  [0.008]
   Land  Length  for  ring  number  0  is:  [0.00391]
        Top  Gap  of  ring  number  0  is:  [6e-05]
     Middle  Gap  of  ring  number  0  is:  [4e-05]
     Bottom  Gap  of  ring  number  0  is:  [6e-05]

           Width  of  ring  number  1  is:  [0.00375]
       Thickness  of  ring  number  1  is:  [0.0015]
         Spacing  of  ring  number  1  is:  [0.008]
   Land  Length  for  ring  number  1  is:  [0.00391]
        Top  Gap  of  ring  number  1  is:  [6e-05]
     Middle  Gap  of  ring  number  1  is:  [4e-05]
     Bottom  Gap  of  ring  number  1  is:  [6e-05]

           Width  of  ring  number  2  is:  [0.00375]
       Thickness  of  ring  number  2  is:  [0.0015]
         Spacing  of  ring  number  2  is:  [0.00391]
   Land  Length  for  ring  number  2  is:  [0.00391]
        Top  Gap  of  ring  number  2  is:  [6e-05]
     Middle  Gap  of  ring  number  2  is:  [4e-05]
     Bottom  Gap  of  ring  number  2  is:  [6e-05]

   Initial  conditions  in  ring  pack
   Pressure  1  is:  [4600623.5]
   Pressure  2  is:  [4173522.5]
   Pressure  3  is:  [3689110.5]
   Pressure  4  is:  [3130620]
   Pressure  5  is:  [2214841.8]
```

A fast way to set up multiple rings in the ring pack is to specify only one ring and enter the geometry. Once the ring geometry is entered, invoke the `crevice-model- controls` menu a second time and specify the number of rings desired. When the number of rings changes, the geometry from the first ring is copied to all subsequent rings. Default values can be taken for the rest of the way through the menu structure.

A summary of the crevice model is printed out by entering the `(crevice-summary)` command at the command prompt:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
>(crevice-summary)
                    crevice/n-rings  :  3
                  crevice/ring-width  :  (0.00375  0.00375  0.00375)
              crevice/ring-thickness  :  (0.0015  0.0015  0.0015)

```

20.3.2. Crevice Model Solution Details

The under-relaxation factor for the crevice model source terms can be found in the **Solution Controls** task page. The default value for **Crevice Model Sources** is 0.8, which has been found to work well for motored engine simulations. Once the crevice model is enabled, the solution proceeds normally.

Solution → **Controls**

Solution → **Initialization**

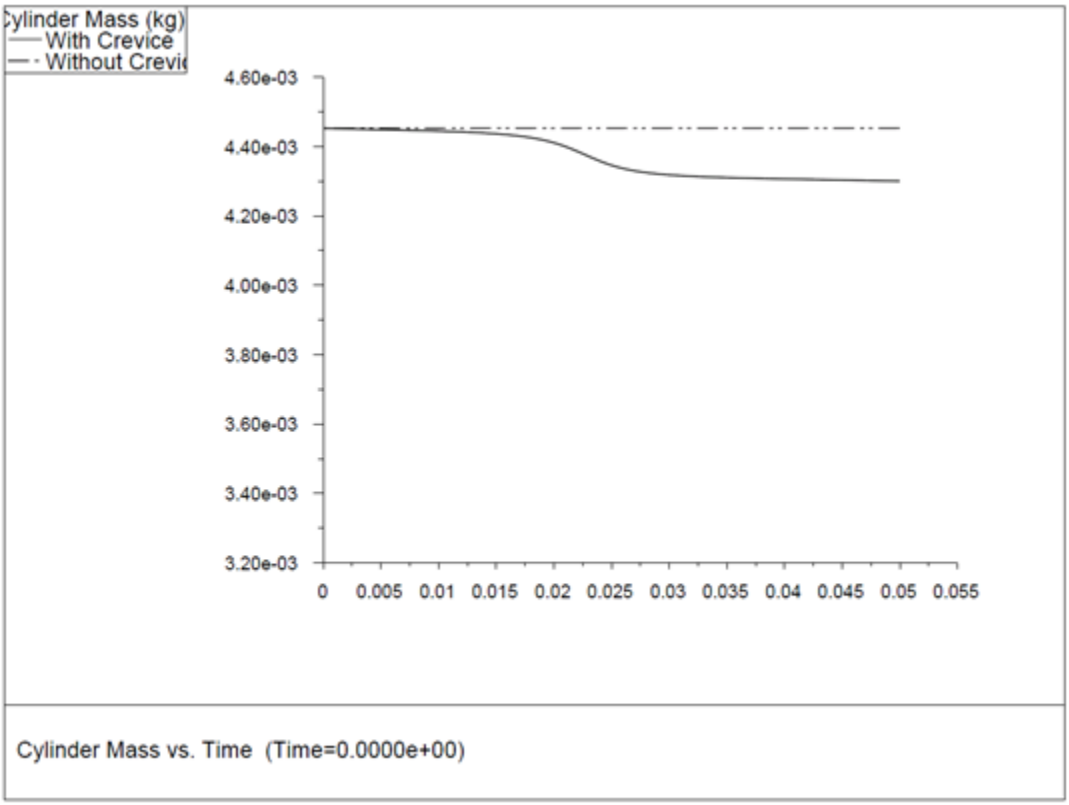
Solution → **Run Calculation**

20.3.3. Postprocessing for the Crevice Model

A plot of cylinder mass with and without the crevice model during the motored engine simulation is shown in Figure 20.9: Cylinder Mass vs. Crank Angle (p. 1149). The rate of mass loss from the crevice is proportional to the pressure difference between the cylinder and the crankcase pressure defined in the text interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

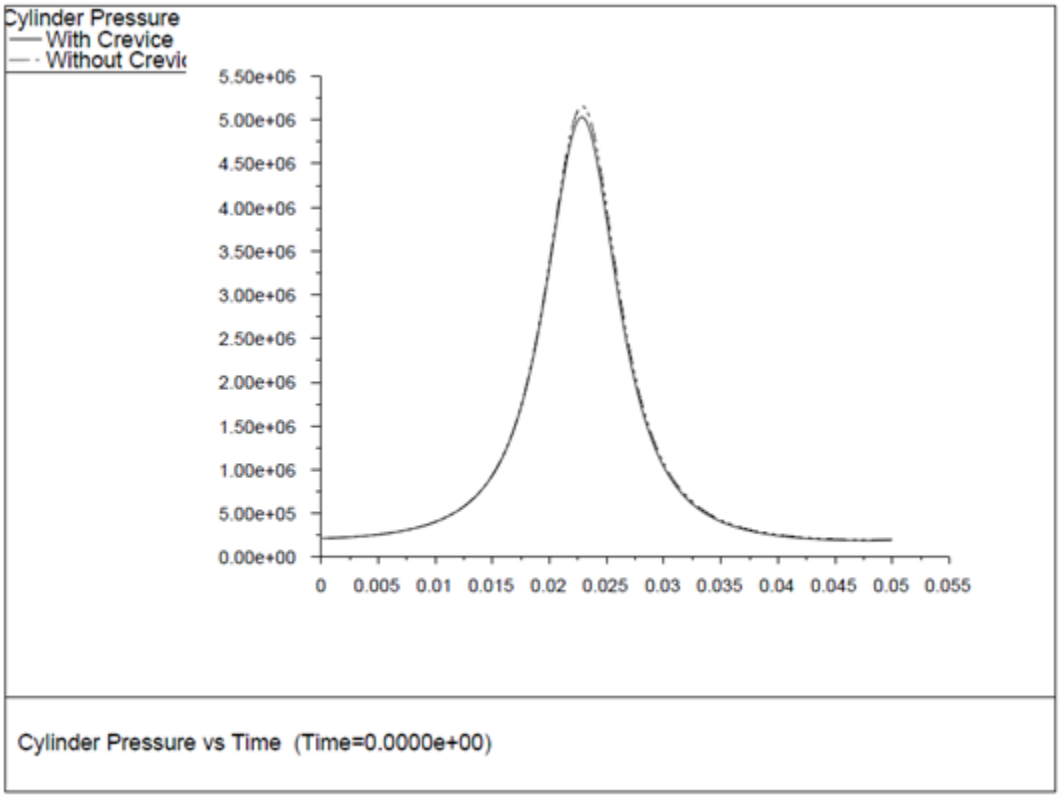
Figure 20.9: Cylinder Mass vs. Crank Angle



A plot of cylinder pressure with and without the crevice model for the same engine simulation is shown in Figure 20.10: Cylinder Pressure vs. Crank Angle (p. 1150). The effect of the mass loss from the crevice is to lower the peak pressure in proportion to the total mass loss from the cylinder.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 20.10: Cylinder Pressure vs. Crank Angle



20.3.3.1. Using the Crevice Output File

The pressure in the top ring land is defined as the cylinder pressure (that is, the pressure in the cells defining the ring landing). Intermediate pressures are available at any point during the ANSYS Fluent session through the `(crevice-summary)` command as previously shown. If the optional data file output is chosen in the `crevice-model-controls`, the intermediate pressures in the defined crevices are printed to the file `crev.out` at the start of each new time step. The format of the file is as follows:

```
  # crank (deg) data-press[0...1...2...3...4...5...6] total_mdot
 1.95500e+02 2.16650e+05 1.01325e+05 1.01325e+05 1.01325e+05 1.01325e+05 1.01325e+05 1.01325e+05 0.0
 1.96000e+02 2.09945e+05 1.06794e+05 1.81553e+05 1.04111e+05 1.48582e+05 1.02202e+05 1.01325e+05 -1.6
 1.96500e+02 2.17787e+05 1.13070e+05 1.88242e+05 1.07960e+05 1.53544e+05 1.03526e+05 1.01325e+05 -1.6
 1.97000e+02 2.17434e+05 1.19065e+05 1.88060e+05 1.11705e+05 1.53475e+05 1.04830e+05 1.01325e+05 -1.6
 1.97500e+02 2.17652e+05 1.24777e+05 1.88299e+05 1.15286e+05 1.53668e+05 1.06081e+05 1.01325e+05 -1.6
 1.98000e+02 2.17937e+05 1.30215e+05 1.88594e+05 1.18711e+05 1.53900e+05 1.07283e+05 1.01325e+05 -1.6
```

where the first column is the current flow time (or crank angle), and the next $n_{cv}+2$ columns are the ring pressures (where n_{cv} is the number of crevice volumes, or $2n_r-1$), including the face pressure on the crevice cell, and the defined pressure at the crevice exit. The final column is the mass flow past the top ring. This file is currently formatted so that it can be read into the free **Gnuplot** plotting package, which is available at `www.gnuplot.info`.

To read the crevice output file into ANSYS Fluent as a data file, you will need to put each column of the crevice output file in its own individual file. The first three lines of each column of the data file should be of the following form:

```
"Title"
"X-Label" "Y-Label"
0 0 0 0
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

where the title, x-label, and y-label strings are enclosed by double quotes and the third line of the file contains four zeros. The lines following the first three lines of the file are the columns you want to plot. For example, to plot column 1 versus column 3 of the crevice model output file in ANSYS Fluent, you would enter the following commands in a Linux terminal:

```
cat > crev_col_1_3.dat
"Column 1 vs Column 3"
"Crank Angle (deg)" "Pressure behind ring 1 (Pa)"
0 0 0 0
ctrl-d
```

where `ctrl-d` is the end-of-file character made holding down the **Ctrl** key and pressing **d** (**Ctrl**+**d**). To append columns 1 and 3 to this file, enter the following:

```
tail +2 crev.out | awk '{print $1, $3}' >> crev_col_1_3.dat
```

The file `crev_col_1_3.dat` can now be read into ANSYS Fluent using the File XY Plot Dialog Box (p. 2599). See XY Plots of File Data (p. 1844) for details about creating x- y plots. For Windows users, the file `crev.out` can be imported into Excel for plotting purposes without any modification.

A **Gnuplot** plot of the pressure in the ring pack crevices for the above engine simulation is shown in Figure 20.11: Crevice Pressures (p. 1151). After an initial transient period where the flows in the network settle down, Figure 20.11: Crevice Pressures (p. 1151) shows that the pressure in the ring crevices follows the cylinder pressure in form, though with pressure magnitudes that are controlled by the ring pack geometry.

Figure 20.11: Crevice Pressures

Chapter 21: Modeling Pollutant Formation

This chapter discusses how to use the models available in ANSYS Fluent for modeling pollutant formation. For information about the theory behind the models in ANSYS Fluent, see Pollutant Formation in the Theory Guide.

Information is presented in the following sections:

21.1. NOx Formation
21.2. SOx Formation
21.3. Soot Formation
21.4. Using the Decoupled Detailed Chemistry Model

21.1. NOx Formation

The following sections describe how to use the NO_x models in ANSYS Fluent. For information about the theory behind the NO_x models in ANSYS Fluent, see NOx Formation in the Theory Guide.

21.1.1. Using the NOx Model
21.1.2. Solution Strategies
21.1.3. Postprocessing

21.1.1. Using the NOx Model

21.1.1.1. Decoupled Analysis: Overview

NO_x concentrations generated in combustion systems are generally low. As a result, NO_x chemistry has negligible influence on the predicted flow field, temperature, and major combustion product concentrations. It follows that the most efficient way to use the NO_x model is as a postprocessor to the main combustion calculation.

The recommended procedure is as follows:

1. Calculate your combustion problem using ANSYS Fluent as usual.

Important

The premixed combustion model is not compatible with the NO_x model.

Important

If you plan to use the ANSYS Fluent SNCR model for NO_x reduction, you must first include ammonia or urea (depending upon which reagent is employed) as a fluid species in the main combustion calculation and define appropriate ammonia injections, as described later in this section. See Defining the Species in the Mixture (p. 973) for details about adding species to your model and Setting Initial Conditions for the Discrete Phase (p. 1265) for details about creating injections.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Enable the desired NO_x models (thermal, prompt, fuel, and/or N_2O intermediate NO_x, with or without reburn), define the fuel streams (for prompt NO_x and fuel NO_x only), and set the appropriate parameters, as described in this section.

   Setup → Models → Species → NOx Edit...

3. Define the boundary conditions for NO (and HCN, NH_3, or N_2O, if necessary) at flow inlets.

   Setup → Boundary Conditions

4. In the Equations Dialog Box (p. 2511), turn off the solution of all variables except species NO (and HCN, NH_3, or N_2O, based on the model selected).

   Solution → Controls → Equations...

5. Perform calculations until convergence (that is, until the NO—and HCN, NH_3, or N_2O, if solved—species residuals are below 10^{-6}) to ensure that the NO and HCN or NH_3 concentration fields are no longer evolving.

   Solution → Run Calculation

6. Review the mass fractions of NO (and HCN, NH_3, or N_2O) by generating graphical plots or alphanumeric reports in the usual way.

7. Save a new set of case and data files, if desired.

   File → Write → Case & Data...

Inputs specific to the calculation of NO_x formation are explained in the remainder of this section.

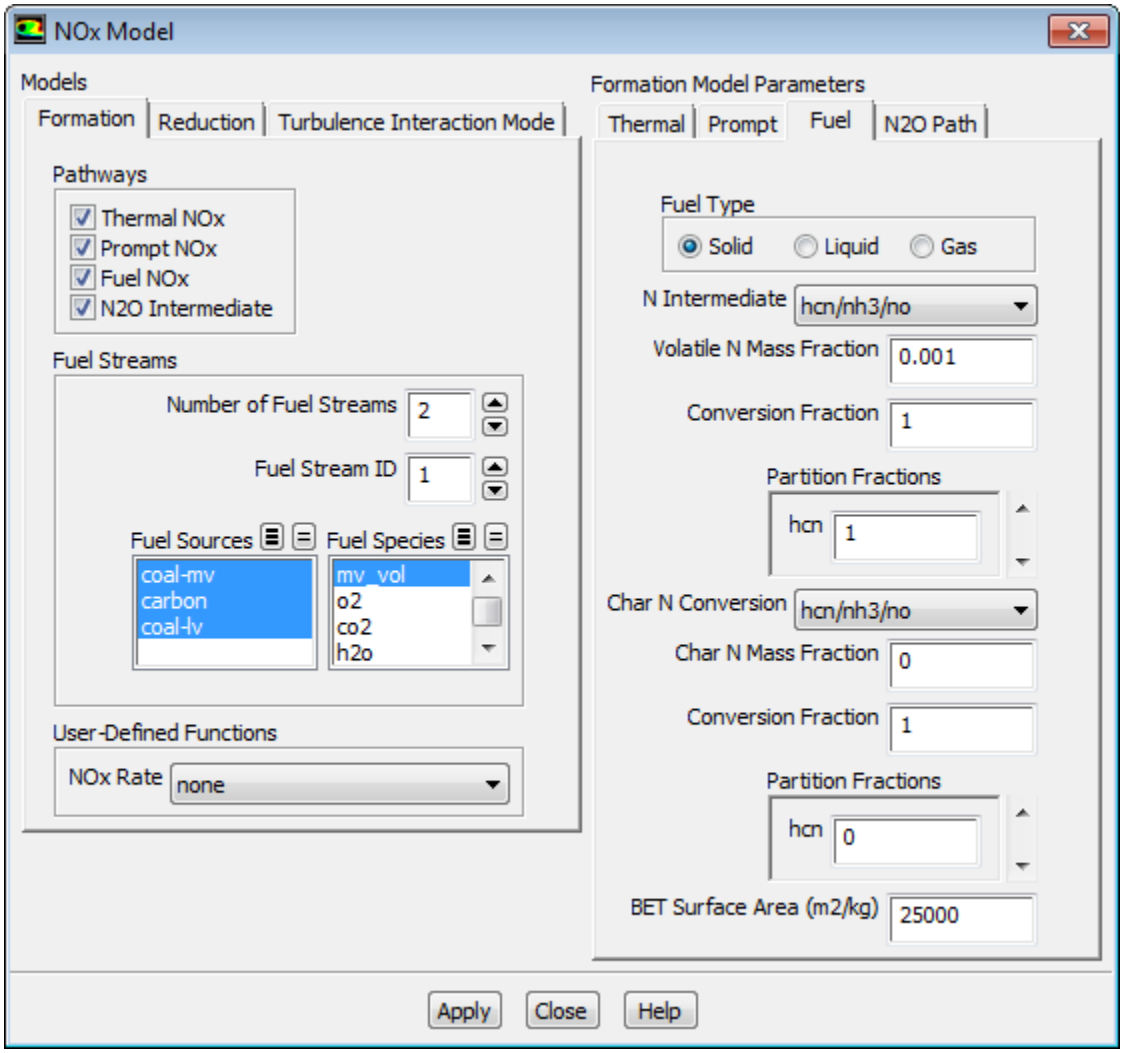
21.1.1.2. Enabling the NOx Models

To enable the NO_x models and set related parameters, you will use the NOx Model Dialog Box (p. 2250) (for example, Figure 21.1: The NOx Model Dialog Box (p. 1155)).

Setup → Models → Species → NOx Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.1: The NOx Model Dialog Box



In the **Formation** tab, select the NO_x models under **Pathways** to be used in the calculation of the NO and HCN, NH_3, or N_2O concentrations:

- To enable thermal NO_x, turn on the **Thermal NOx** option.
- To enable prompt NO_x, turn on the **Prompt NOx** option.
- To enable fuel NO_x, turn on the **Fuel NOx** option.

Important

When using the non-premixed combustion model, the following limitation exist for the **Fuel NOx** option:

– The **Fuel NOx** option is only available if the DPM model is also enabled.

- To enable the formation of NO_x through an N_2O intermediate, turn on the **N2O Intermediate** option. (Note that the **N2O Intermediate** option will not appear until you have enabled one of the other NO models listed above.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Your selection(s) under **Pathways** will enable the calculation of thermal, prompt, fuel, and/or N_2O-intermediate NO_x in accordance with the chemical kinetic models described in Thermal NOx Formation through NOx Formation from Intermediate N2O in the Theory Guide. Mean NO formation rates will be computed directly from mean concentrations and temperature in the flow field.

21.1.1.3. Defining the Fuel Streams

When modeling fuel NO_x formation, ANSYS Fluent allows you to define up to three separate fuel streams, and to select the fuel N sources for each fuel stream.

You can define multiple fuel streams to include in your model with the following configurations:

- Solid and liquid fuels (combusting particle and droplet) both contributing to fuel NO_x.
- Two or three solid fuels with different N-content and NO_x model parameters (two or three combusting particles), for example coal blends, coal-biomass cofiring, and so on.
- Two or three liquid fuels with different N-content and NO_x model parameters (two or three droplet or multicomponent particles).
- Gas and solid (or droplet) fuel both contributing to fuel NO_x.

  In addition, you can model one solid fuel contributing to NO_x in the presence of another reacting solid particle not containing any N, for example sorbent injection in a coal furnace, calcination reaction in cement kiln and so on, by specifying the active N fuel source for NO_x formation. For this configuration, you will not need to define multiple fuel streams in your model.

If **Fuel NOx** is enabled in the **Pathways** group box in the **Formation** tab, perform the following steps to define multiple fuel streams:

1. Specify the **Number of Fuel Streams** in the **Fuel Streams** group box.

   Note

   You are allowed up to three separate fuel streams.

2. Define the first fuel stream.

   a. Select the fuel stream to be defined by using the arrow keys of the **Fuel Stream ID** field.

   b. Select the **Fuel Type** in the **Fuel** tab for the **Formation Model Parameters**.

   c. If your **Fuel Type** is **Liquid** or **Solid**, select the N sources from the **Fuel Sources** list.

   - If the **Fuel Type** is **Solid** and you have defined multiple injections with different combusting particle materials in your reacting flow calculation, the available combusting particle materials will be listed in the **Fuel Sources** list. Select one or more materials from the list to be included as fuel sources in the **Fuel NOx** calculation. Your selection will be used to determine the char burnout rate S_c and volatile release rate S_{vol} in the coal fuel NO_x formation rate models described in Fuel NOx from Coal in the Theory Guide. Make sure to deselect all combusting particle materials that do not contribute to NO_x.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If the **Fuel Type** is **Liquid** and you have defined multiple injections with different droplet or multicomponent particle materials in your reacting flow calculation, the available materials will be listed in the **Fuel Sources** list. Select one or more materials from the list to be included as fuel sources in the **Fuel NOx** calculation. Your selection will be used to determine the fuel release rate S_{fuel} in the liquid fuel NO_x formation rate models described in Fuel NOx from Intermediate Hydrogen Cyanide (HCN) and Fuel NOx from Intermediate Ammonia (NH3) in the Theory Guide. Make sure to deselect all droplet and multicomponent materials that do not contribute to NO_x.

d. If you are also modeling **Prompt NOx**, select the fuel species from the **Fuel Species** list. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10. You can define the same, or different **Fuel Species**, **Fuel Carbon Number** and **Equivalence Ratio** for each stream. The **Fuel Carbon Number** and **Equivalence Ratio** can be modified in the **Prompt** tab under **Formation Model Parameters**.

e. If the **Fuel Type** in your model is **Gas**, select one or more materials from the **Fuel Species** list. Your selection will be used to determine the mean limiting reaction rate $\mathcal{R}_{cf}$ in the gaseous fuel NO_x formation rate models described in Fuel NOx from Intermediate Hydrogen Cyanide (HCN) and Fuel NOx from Intermediate Ammonia (NH3) in the Theory Guide. If you are also modeling **Prompt NOx** formation, the same fuel selection will apply also for the prompt NO_x model.

f. Set the other parameters associated with your selected pathway(s) in the **Prompt** and/or **Fuel** tabs under **Formation Model Parameters**. See Setting Prompt NOx Parameters (p. 1159) and Setting Fuel NOx Parameters (p. 1160) for details.

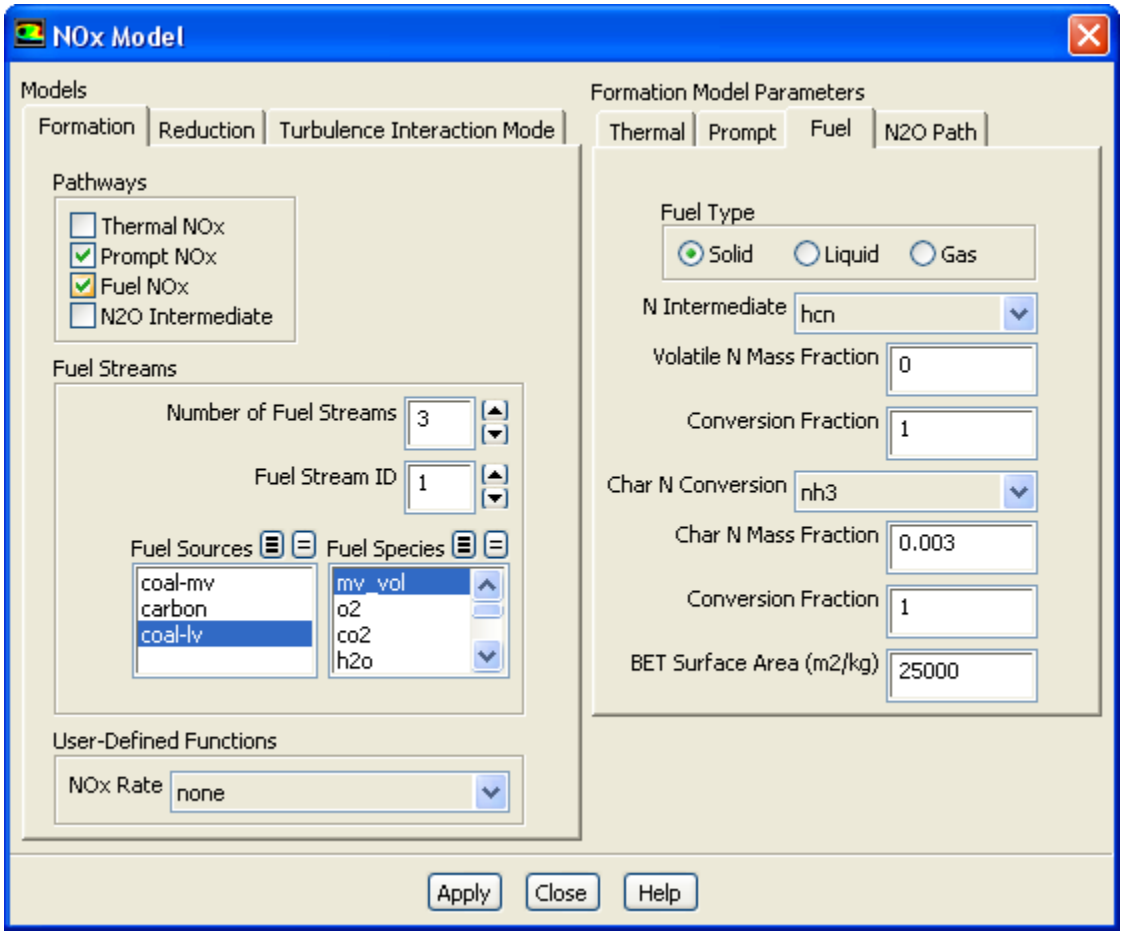
3. Repeat steps 2.(a)–2.(f) for each additional fuel stream.

Important

The gaseous fuel option is available only when the species model is enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.2: The NOx Model Dialog Box Displaying the Fuel Streams



Important

Important considerations should be made when reading case and data files set up in a version of ANSYS Fluent 14.5 or earlier:

- When reading a case and data file with multiple injection materials that was set up in a version of ANSYS Fluent previous to and including 14.5, ANSYS Fluent will initialize the injection material specific fuel N sources for the fuel NO_x model. ANSYS Fluent will perform a DPM iteration when the flow iterations are initiated.
- When reading a case file that was set up in a version older than ANSYS Fluent 14.5 with multiple fuel streams defined for the **Fuel NOx** model, you must review the setup and select the N sources from the **Fuel Sources** list.

21.1.1.4. Specifying a User-Defined Function for the NOx Rate

You can choose to specify a user-defined function for the rate of NO_x production. By default, the rate returned from the UDF is added to the rate returned from the standard NO_x production options, if any are selected. You also have the option of replacing any or all of ANSYS Fluent's NO_x rate calculations with your own user-defined NO_x rate.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In addition to or instead of using the UDF to specify the NO_x rate, you can use it to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

To use a UDF to add a rate to ANSYS Fluent's NO_x rate calculations, you must compile and load the desired function, and then select it from the **NOx Rate** drop-down list in the **User-Defined Functions** group box in the **Formation** tab. After you have selected the UDF, you have the following options:

- You can specify that your custom rate is added to the ANSYS Fluent NO_x rate calculations, by retaining the default selection of **Add to Fluent Rate** in the **UDF Rate** group box for the appropriate NO_x formation pathway(s) (for example, in the **Fuel** tab).
- You can replace the ANSYS Fluent NO_x rate calculations with your custom rate, by selecting **Replace Fluent Rate** in the **UDF Rate** group box for the appropriate NO_x formation pathway(s) (for example, in the **Fuel** tab).
- You can specify custom values for T_{max}, by selecting **user-defined** from the **Tmax Option** drop-down list in the **Turbulence Interaction Mode** tab.

See the Fluent Customization Manual for details about user-defined functions.

21.1.1.5. Setting Thermal NOx Parameters

The NO_x routines employ three methods for calculation of thermal NO_x (as described in Method 1: Equilibrium Approach in the Theory Guide). You will specify the method to be used in the **Thermal** tab, under **Formation Model Parameters** in the NOx Model Dialog Box (p. 2250):

- To choose the equilibrium method, select **equilibrium** in the **[O] Model** drop-down list.
- To choose the partial equilibrium method, select **partial-equilibrium** in the **[O] Model** or **[OH] Model** drop-down list.
- To use the predicted O and/or OH concentration, select **instantaneous** in the **[O] Model** or **[OH] Model** drop-down list.

Important

Note that the urea model uses the $[OH]$ model.

If you hooked a user-defined function in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace Fluent Rate** to replace ANSYS Fluent's thermal NO_x rate calculations with the custom NO_x rate produced by your UDF.
- Select **Add to Fluent Rate** to add the custom NO_x rate produced by your UDF to ANSYS Fluent's thermal NO_x rate calculations.

21.1.1.6. Setting Prompt NOx Parameters

Prompt NO_x formation is predicted using Equation 14.26 and Equation 14.28 in the Theory Guide. For each fuel stream specified in the **Fuel Stream ID** field in the **Formation** tab, set the parameters in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Prompt tab under **Formation Model Parameters** in the NOx Model Dialog Box (p. 2250) in the following manner:

- Set the **Fuel Carbon Number** to specify the number of carbon atoms per fuel molecule.
- Set the **Equivalence Ratio** as follows:

$$\text{Equivalence Ratio}=\frac{\text{actual fuel-to-air ratio}}{\text{stoichiometric fuel-to-air ratio}} \tag{21.1}$$

If you hooked a user-defined function in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace Fluent Rate** to replace ANSYS Fluent's prompt NO_x rate calculations with the custom NO_x rate produced by your UDF.
- Select **Add to Fluent Rate** to add the custom NO_x rate produced by your UDF to ANSYS Fluent's prompt NO_x rate calculations.

21.1.1.7. Setting Fuel NOx Parameters

When using the fuel NO_x model, you must set the parameters in the **Fuel** tab under **Formation Model Parameters** for each fuel stream specified in the **Fuel Stream ID** field in the **Formation** tab.

If you hooked a user-defined function in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace Fluent Rate** to replace ANSYS Fluent's fuel NO_x rate calculations with the custom NO_x rate produced by your UDF.
- Select **Add to Fluent Rate** to add the custom NO_x rate produced by your UDF to ANSYS Fluent's fuel NO_x rate calculations.

If there is no NO_x rate UDF or if you selected **Add to Fluent Rate**, you must define fuel parameters. To begin, specify the fuel type in the following manner:

- For solid fuel NO_x, select **Solid** under **Fuel Type**.
- For liquid fuel NO_x, select **Liquid** under **Fuel Type**.
- For gaseous fuel NO_x, select **Gas** under **Fuel Type**.

Note that you can use only one of the fuel types for a given fuel stream. The **Gas** option is available only when the **Species Transport** model is enabled (see Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960)).

21.1.1.7.1. Setting Gaseous and Liquid Fuel NOx Parameters

If you have selected **Gas** or **Liquid** as the **Fuel Type**, you must also specify the following:

- Select the intermediate species (**hcn**, **nh3**, or **hcn/nh3/no**) in the **N Intermediate** drop-down list.
- Set the correct mass fraction of nitrogen in the fuel (kg nitrogen per kg fuel) in the **Fuel N Mass Fraction** field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Specify the overall fraction of the fuel N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field. The **Conversion Fraction** for the **N Intermediate** has a default value of 1. Therefore, any remaining N will not contribute to NO_x formation. This is based on the assumption that the remaining volatile N will convert to gas phase nitrogen. However, this has very little effect on the overall mass fraction of gas phase nitrogen. Therefore, you do not have to solve for nitrogen species when solving pollutant transport equations.

- If you selected **hcn/nh3/no** as the intermediate, specify the fraction of the converted fuel N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of fuel N that will become NO will be calculated by the remainder.

  Note that setting a partition fraction of 0 for both HCN and NH_3 is equivalent to assuming that all fuel N is converted to the final product NO, whereas a partition fraction of 0 for HCN and 1 for NH_3 is the same as selecting **nh3** as the intermediate.

ANSYS Fluent will use Equation 14.31 and Equation 14.32 in the Theory Guide (for HCN) or Equation 14.42 and Equation 14.43 in the Theory Guide (for NH_3) to predict NO formation for a gaseous or liquid fuel.

Important

Note that there is a limitation that must be considered when defining more than one liquid fuel stream. See Defining the Fuel Streams (p. 1156) for details.

21.1.1.7.2. Setting Solid (Coal) Fuel NOx Parameters

For solid (coal) fuel, ANSYS Fluent will use Equation 14.55 and Equation 14.56 in the Theory Guide (for HCN) or Equation 14.62 and Equation 14.63 in the Theory Guide (for NH_3) to predict NO formation. Several inputs are required for the coal fuel NO_x model as follows:

- Select the intermediate species (**hcn**, **nh3**, or **hcn/nh3/no**) in the **N Intermediate** drop-down list.

- Specify the mass fraction of nitrogen in the volatiles in the **Volatile N Mass Fraction** field.

- Specify the overall fraction of the volatile N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field.

- If you selected **hcn/nh3/no** as the volatile N intermediate, specify the fraction of the converted volatile N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of volatile N that will become NO will be calculated by the remainder.

- Select the char N conversion path from the **Char N Conversion** drop-down list as **no**, **hcn**, **nh3**, or **hcn/nh3/no**. Note that **hcn** or **nh3** can be selected only if the same species has been selected as the intermediate species in the **N Intermediate** drop-down list.

- Specify the mass fraction of nitrogen in the char in the **Char N Mass Fraction** field.

- Specify the overall fraction of the char N, by mass, that will be converted to the intermediate species and/or product NO in the **Conversion Fraction** field.

- If you selected **hcn/nh3/no** as the char N conversion, specify the fraction of the converted char N, by mass, that will become **hcn** and **nh3** under **Partition Fractions**. The fraction of char N that will become NO will be calculated by the remainder.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Define the BET internal pore surface area (see BET Surface Area in the Theory Guide for details) of the particles in the **BET Surface Area** field.

Important

Note that there are limitations that must be considered when defining more than one solid fuel stream. See Defining the Fuel Streams (p. 1156) for details.

The following equations are used to determine the mass fraction of nitrogen in the volatiles and char:

$$\dot{m}_{N_{v/c}} = \dot{m}_{v/c} * mf_{N_{v/c}} \tag{21.2}$$

where

$\dot{m}_{N_{v/c}}$ = rate of release of fuel nitrogen in kg/s

$\dot{m}_{v/c}$ = rate of release of volatiles (v) or char (c) in kg/s

$mf_{N_{v/c}}$ = mass fraction of nitrogen in volatiles or char

Let

TN_{fuel} = total nitrogen mass fraction in daf coal (that is, from daf ultimate analysis)

N_{split} = char nitrogen as a fraction of total nitrogen

F_{vol} = mass fraction of volatiles in daf coal

F_{char} = mass fraction of char in daf coal

Then the following should hold:

$$F_{vol} + F_{char} = 1 \tag{21.3}$$

$$\frac{F_{char} * mf_{N_c}}{TN_{fuel}} = N_{split} \tag{21.4}$$

$$F_{vol} * mf_{N_v} + F_{char} * mf_{N_c} = TN_{fuel} \tag{21.5}$$

$$mf_{N_v} = \left(1 - N_{split}\right) * \frac{TN_{fuel}}{F_{vol}} \tag{21.6}$$

$$mf_{N_c} = N_{split} * \frac{TN_{fuel}}{F_{char}} \tag{21.7}$$

21.1.1.8. Setting N2O Pathway Parameters

The formation of NO through an N_2O intermediate can be predicted by two methods. You will specify the method to be used in the **N2O Path** tab.

- To choose the quasi-steady-state method, select **quasi-steady** in the **N2O Model** drop-down list.

Important

The transport equation for the species N_2O will not be solved for N_2O. However, N_2O will be updated at every iteration. Therefore, the residual values that appear for N_2O are always zero. Do not be alarmed if the solver keeps printing zero at each iteration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- To choose the simplified form of the N_2O-intermediate mechanism, select **transported-simple** in the **N2O Model** drop-down list. Here, the species N_2O is added to the list of pollutant species, and its mass fraction is solved via a transport equation.

The atomic O concentration will be calculated according to the thermal NO_x **[O] Model** that you have specified previously. If you have not selected the **Thermal NOx** pathway, then you will be given the option to specify an **[O] Model** for the N_2O pathway calculation. The same three options for the thermal NO_x **[O] Model** will be the available options.

If you hooked a user-defined function in the **Formation** tab, you can make a selection in the **UDF Rate** group box to specify the treatment of the user-defined NO_x rate:

- Select **Replace Fluent Rate** to replace the NO_x rate calculated by ANSYS Fluent using N_2O intermediates with the custom NO_x rate produced by your UDF.
- Select **Add to Fluent Rate** to add the custom NO_x rate produced by your UDF to the NO_x rate calculated by ANSYS Fluent using N_2O intermediates.

21.1.1.9. Setting Parameters for NOx Reburn

To enable NO_x reduction by reburning, click the **Reduction** tab in the NOx Model Dialog Box (p. 2250) and enable the **Reburn** option under **Methods**. In the expanded portion of the dialog box, as shown in Figure 21.3: The NOx Dialog Box Displaying the Reburn Reduction Method (p. 1164), click the **Reburn** tab under **Reduction Method Parameters**, where you can choose from the following options:

- To choose the instantaneous method, select **instantaneous [CH]** in the **Reburn Model** drop-down list.

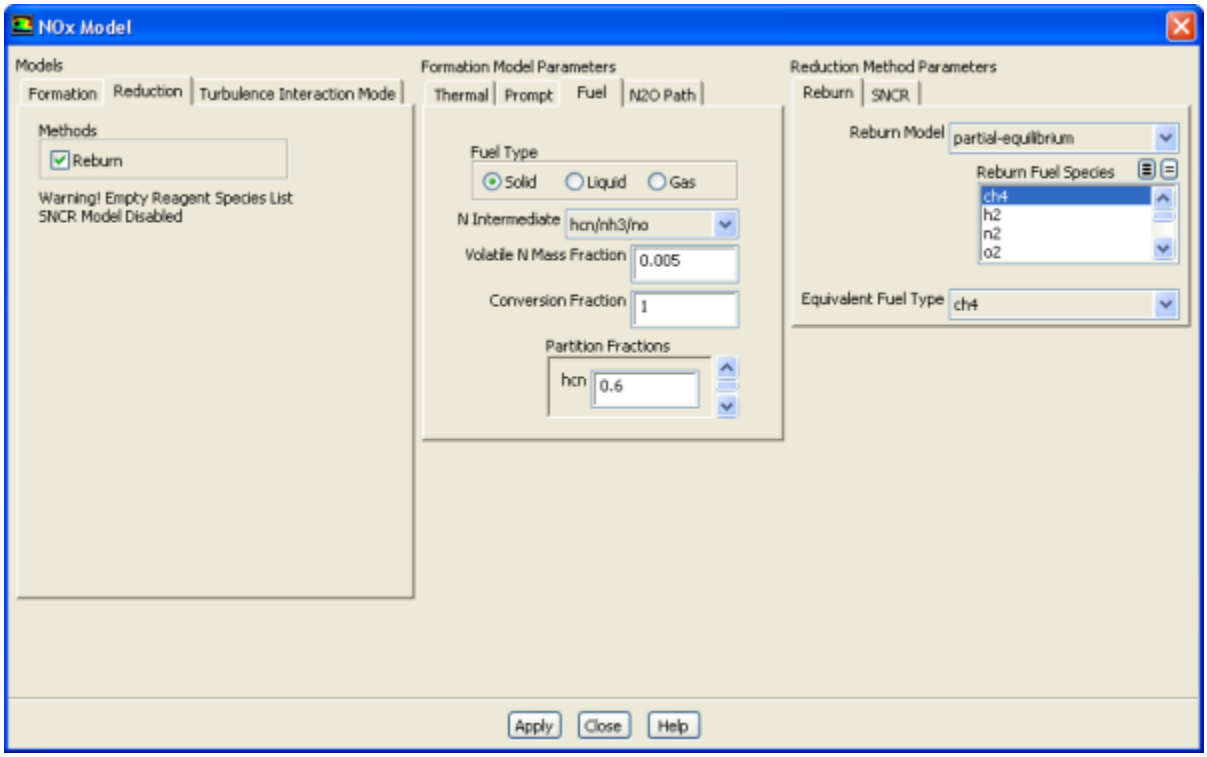
  Important

  When you use this method, you must be sure to include the species CH, CH_2, and CH_3 in your problem definition. See NOx Reduction by Reburning in the Theory Guide for details.

- To choose the partial equilibrium method, select **partial-equilibrium** in the **Reburn Model** drop-down list. You then must select the **Reburn Fuel Species** from the list of available species. ANSYS Fluent will allow you select up to five reburn fuel species. Specify the **Equivalent Fuel Type** (**ch4**, **ch3**, **ch2**, or **ch**). For example, if you choose methane as the reburn fuel, then the **Equivalent Fuel Type** would be **ch4**. If you choose a reburn fuel such as **hv_vol** (a volatile component of coal), then you must specify the most appropriate equivalent hydrocarbon fuel type so that the partial equilibrium model will be set up correctly.
- Due to coal volatiles behaving very differently, it is important to select the correct equivalent fuel type. You must first consider the volatile fuel composition, then check the C/H ratio to find the fuel that most closely matches CH, CH_2, CH_3, or CH_4 [60] (p. 2890). While the method for best determining the equivalent fuel is debatable, considering the C/H ratio of the fuel itself is a reasonable indicator.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.3: The NOx Dialog Box Displaying the Reburn Reduction Method



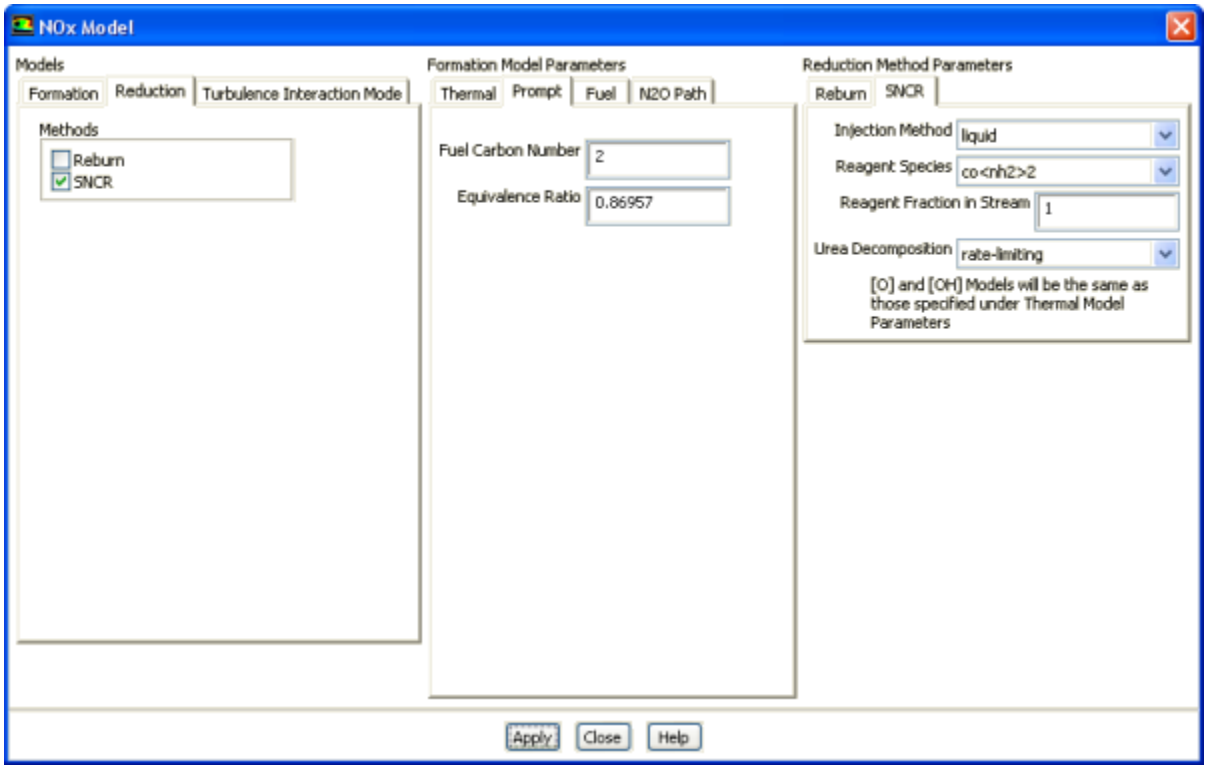
21.1.1.10. Setting SNCR Parameters

Prior to enabling reduction by SNCR, make sure that you have included in the species list **nh3** (for reduction by ammonia injection) and **co<nh2>2** (for reduction by urea injection). See NOx Reduction by SNCR in the Theory Guide for detailed information about SNCR theory.

To enable NO_x reduction by SNCR, click the **Reduction** tab in the NOx Model Dialog Box (p. 2250) and enable the **SNCR** option under **Methods**, as shown in Figure 21.4: The NOx Dialog Box Displaying the SNCR Reduction Method (p. 1165).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.4: The NOx Dialog Box Displaying the SNCR Reduction Method



Then click the **SNCR** tab under **Reduction Method Parameters**, where you can choose from the following options:

- To have ammonia or urea included as a gas-phase pollutant species from the injection locations, select **gaseous** in the **Injection Method** drop-down list.

  If you plan to select this option for NO_x postprocessing, then you must also include ammonia or urea as a gas-phase species. Additionally, you must specify the mass fraction of ammonia or urea at the respective inlet for the SNCR injection. You must include this set of inputs prior to the main ANSYS Fluent combustion calculation.

- To have ammonia included as a liquid-phase pollutant species from the injection locations, select **liquid** in the **Injection Method** drop-down list. If urea is injected as a liquid solution, then select **liquid** in the **Injection Method** drop-down list. Note that you must enable the DPM model with urea or ammonia included as a material.

  Note

  All particle types such as droplets, combusting, and multicomponent particles are compatible with the SNCR model.

  If you plan to select this option for NO_x postprocessing, then you must include NH_3 as both a gas-phase and liquid-phase species. Additionally, you must specify injection locations for liquid droplet ammonia particles and set gaseous ammonia as the evaporation species. You must include this set of inputs in conjunction with the main ANSYS Fluent combustion calculation.

  Since urea is a subliming solid, and usually is injected as a solution, mixed in water, you have to define solid properties for urea under the Create/Edit Materials Dialog Box (p. 2302). It is assumed that

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the water evaporates before urea begins its subliming process. The sublimation process is modeled similar to the single rate devolatilization model of coal. You will supply the value for the sublimation rate (s^{-1}). You must specify the water content while defining the injection properties.

- Specify the SNCR **Reagent Species** as **nh3** (ammonia) or **co<nh2>2** (urea) in the drop-down list.
- When using the non-premixed combustion model with a liquid-phase reagent injection, enter a value in the **Reagent Fraction in Stream** to specify the mass fraction of the reagent in the reagent stream. The remaining mass fraction is assumed to be water. If you enabled a secondary stream in your PDF calculation, by default the secondary stream will act as the reagent stream. You can assign the primary stream as the reagent stream by using the text command that follows (enter `0` in response to the `PDF Stream ID` prompt that follows the `Injection Method` prompt):

  ```
  define/models/nox-parameters/nox-chemistry
  ```

- If the **Reagent Species** selected is **co <nh2> 2**, then you will either accept the **rate-limiting** option for **Urea Decomposition**, or specify the **NH3 Conversion** value when selecting a **user-specified Urea Decomposition**.

  You will use the urea decomposition under the **SNCR** tab to define which of the two decomposition models is to be used. The first model (which is the default) is the rate-limiting decomposition model, as given in Table 14.3: Two-Step Urea Breakdown Process in the Theory Guide. ANSYS Fluent will then calculate the source terms according to the rates given in Table 14.3: Two-Step Urea Breakdown Process in the Theory Guide. The second model is for when you assume that the urea decomposes instantly into ammonia and $HNCO$ at a given proportion. In this case, you will specify the molar conversion fraction for ammonia, assuming that the rest of the urea is converted to $HNCO$. An example value is given above.

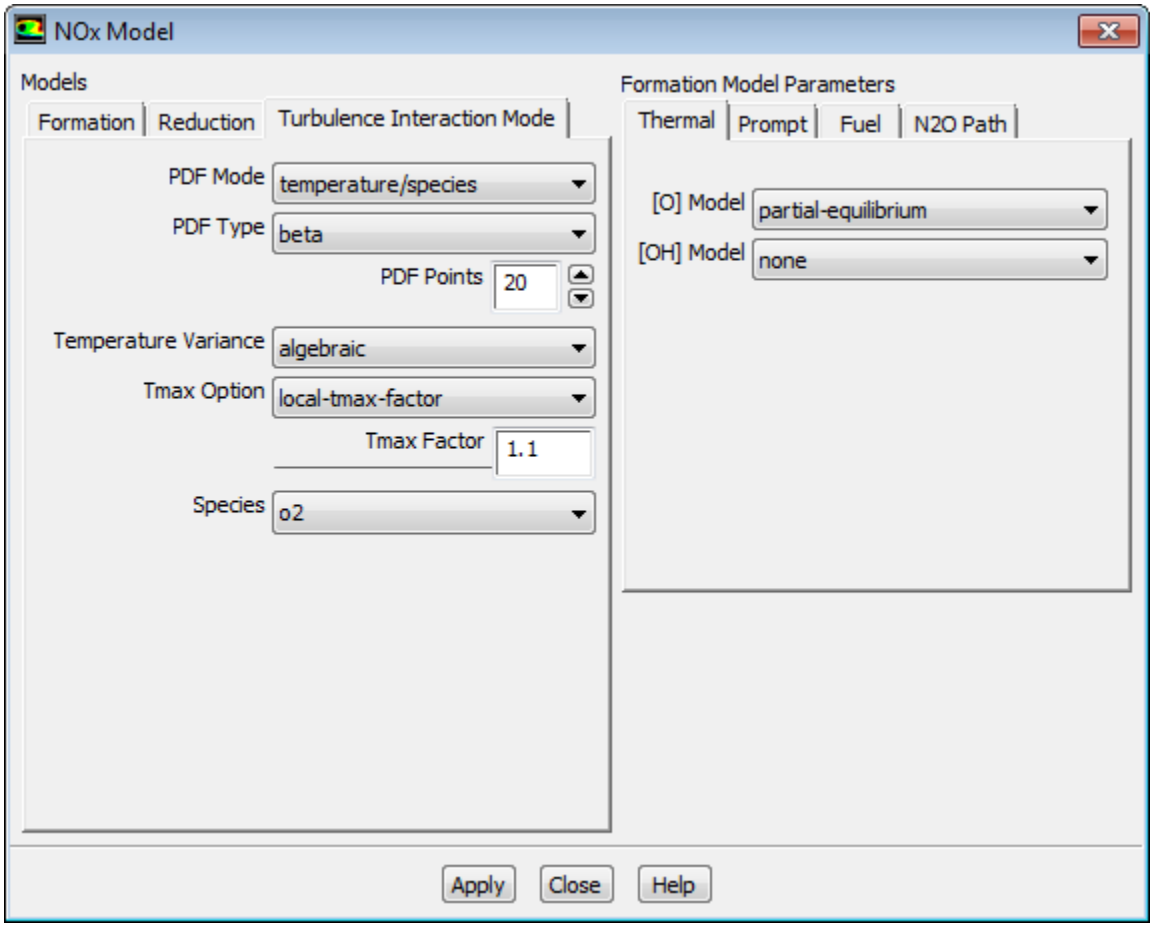
  The value for **user-specified** NH_3 conversion is the mole fraction of NH_3 in the mixture of NH_3 and $HNCO$ that is instantly created from the reagent injection. In this case, there is no urea source because all of reagent is assumed to convert to both NH_3 and $HNCO$, instantly.

21.1.1.11. Setting Turbulence Parameters

If you want to take into account turbulent fluctuations (as described in NOx Formation in Turbulent Flows in the Theory Guide) when you compute the specified NO_x formation (thermal, prompt, and/or fuel, with or without reburn), define the turbulence parameters in the **Turbulence Interaction Mode** tab.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.5: The NOx Model Dialog Box and the Turbulence Interaction Mode Tab



Select one of the options in the **PDF Mode** drop-down list in the **Turbulence Interaction Mode** tab:

- Select **temperature** to take into account fluctuations of temperature.
- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s).

Important

When modeling the formation of other pollutants along with NO_x, you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** group boxes of the NOx Model Dialog Box (p. 2250) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially pre-mixed combustion model to model the reacting system. If you use the **mixture fraction** option, the instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous NO_x rates are calculated at each cell. The PDF used for convoluting the instantaneous NO_x rates is the same as the one used to compute the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF for mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous NO_x rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

Note

When `mixture fraction` is selected as **PDF mode**, ANSYS Fluent calculates and tabulates the NO_x rates apriori for faster computations of NO_x rates. The NO_x rates are tabulated at the first NO_x iteration and a message

```
Performing Pollutant PDF integrations...
```

is displayed in the Fluent console.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** tab:

PDF Type
allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using Equation 14.108 in the Theory Guide. If you select **gaussian**, the PDF will be modeled using Equation 14.111 in the Theory Guide.

PDF Points
allows you to specify the number of points used to integrate the beta or Gaussian function in Equation 14.105 or Equation 14.106 in the Theory Guide on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (for example, 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance
allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see Equation 14.114 of the Theory Guide). You have the option of selecting **transported** to instead solve Equation 14.113 in the Theory Guide. Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option
provides various options for determining the maximum limit of the temperature used for the integration of the PDF (see Equation 8.43 in the *Fluent Theory Guide*) to calculate mean rates for turbulent fluctuations of NO_x:

- The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field.
- You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.
- You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you have selected a user-defined function in the **NOx Rate** drop-down list in the **Formation** tab, then you can select **user-defined** so that the temperature limit is specified by a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

Species

only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the NO_x formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation (Equation 14.114 in the Theory Guide).

21.1.1.12. Defining Boundary Conditions for the NOx Model

At flow inlet boundaries, you must specify the **Pollutant NO Mass Fraction**, and if necessary, the **Pollutant HCN Mass Fraction**, **Pollutant NH3 Mass Fraction**, and **Pollutant N2O Mass Fraction**.

Setup → **Boundary Conditions**

You can retain the default inlet values of zero for these quantities or you can enter nonzero numbers as appropriate for your combustion system.

21.1.2. Solution Strategies

To solve for NO_x products, perform the following steps:

- (optional) If the discrete phase model (DPM) is turned on (by enabling the **Interaction with Continuous Phase**) to run with the NO_x model, then set the **DPM Iteration Interval** to `0` such that no DPM iterations are performed as the NO_x case is being solved.
- In the Equations Dialog Box (p. 2511) of the Solution Controls Task Page (p. 2508), turn off the solution of all variables except species NO (and HCN, NH_3, or N_2O, based on the model selected).

  Solution → **Controls** → **Equations...**
- In the **Solution Controls** task page, set a suitable value for the NO (and HCN, NH_3, or N_2O, if appropriate) under-relaxation. A value of 1.0 is suggested, although lower values may be required for certain problems (that is, if convergence cannot be obtained, try a lower under-relaxation value).
- In the Residual Monitors Dialog Box (p. 2789), decrease the convergence criterion for NO (and HCN, NH_3, or N_2O, if appropriate) to 10^{-6}.

  Solution → **Monitors** → **Residuals** **Edit...**
- Perform calculations until convergence (that is, until the NO—and HCN, NH_3, or N_2O, if solved—species residuals are below 10^{-6}) to ensure that the NO and HCN or NH_3 concentration fields are no longer evolving.

  Solution → **Run Calculation**

21.1.3. Postprocessing

When you compute NO_x formation, the following additional variables will be available for postprocessing:

- **Mass fraction of Pollutant no**
- **Mass fraction of Pollutant hcn** (appropriate fuel NO_x model only)
- **Mass fraction of Pollutant nh3** (appropriate fuel NO_x model only)
- **Mass fraction of Pollutant n2o** (N_2O-intermediate model only)
- **Mass fraction of Pollutant urea** (SNCR urea injection)
- **Mass fraction of Pollutant hnco** (SNCR urea injection)
- **Mass fraction of Pollutant nco** (SNCR urea injection)
- **Mole fraction of Pollutant no**
- **Mole fraction of Pollutant hcn** (appropriate fuel NO_x model only)
- **Mole fraction of Pollutant nh3** (appropriate fuel NO_x model only)
- **Mole fraction of Pollutant n2o** (N_2O-intermediate model only)
- **Mole fraction of Pollutant urea** (SNCR urea injection)
- **Mole fraction of Pollutant hnco** (SNCR urea injection)
- **Mole fraction of Pollutant nco** (SNCR urea injection)
- **no Density**
- **hcn Density** (appropriate fuel NO_x model only)
- **nh3 Density** (appropriate fuel NO_x model only)
- **n2o Density** (N_2O-intermediate model only)
- **urea Density** (SNCR urea injection)
- **hnco Density** (SNCR urea injection)
- **nco Density** (SNCR urea injection)
- **Rate of no** (from the individual pathways)
- **Rate of hcn** (appropriate fuel NO_x model only)
- **Rate of nh3** (appropriate fuel NO_x model only)
- **Rate of n2o** (N_2O-intermediate model only)
- **Rate of urea** (SNCR urea injection)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Rate of hnco** (SNCR urea injection)
- **Rate of nco** (SNCR urea injection)

These variables are contained in the **NOx...** category of the variable selection drop-down list that appears in postprocessing dialog boxes. Additional NO rates from individual pathways, **Thermal**, **Prompt**, **Fuel**, **N2O Path**, and **SNCR** can be plotted.

21.2. SOx Formation

The following sections describe how to use the SO_x model in ANSYS Fluent. For information about the theory behind the SO_x models in ANSYS Fluent, see SOx Formation in the Theory Guide.

21.2.1. Using the SOx Model
21.2.2. Solution Strategies
21.2.3. Postprocessing

21.2.1. Using the SOx Model

When the sulfur content in the fuel is low, SO_x concentrations that are generated in combustion generally have minimal influence on the predicted flow field, temperature, and major combustion product concentrations. The most efficient way to use the SO_x model is as a postprocessor to the main combustion calculation. However, if the sulfur content is high, then SO_x formation should be coupled with the gas phase combustion process rather than treating it as a postprocessing step.

The procedure for enabling and setting up the model for a decoupled solution is as follows:

1. Calculate your combustion problem using ANSYS Fluent.

   Important

   The premixed combustion model and the Flamelet generated manifold model are not compatible with the SO_x model.

2. Enable the SO_x model, define the fuel streams, and set the appropriate parameters, as described in this section.

   Setup → **Models** → **Species** → **SOx** **Edit...**

3. Define the boundary conditions for SO_2 and H_2S (and SO_3, SH, or SO if necessary) at flow inlets.

   Setup → **Boundary Conditions**

4. In the Equations Dialog Box (p. 2511), turn off the solution of all variables except species SO_2 and H_2S (and SO_3, SH, or SO, based on your selections).

   Solution → **Controls** → **Equations...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Perform calculations until convergence (that is, until the SO_2 and H_2S—and SO_3, SH, or SO, if solved—species residuals are below 10^{-6}) to ensure that the SO_2 and H_2S concentration fields are no longer evolving.

   Solution → **Run Calculation**

6. Review the mass fractions of SO_2 and H_2S (and SO_3, SH, or SO) by generating graphical plots or alphanumeric reports in the usual way.

7. Save a new set of case and data files, if desired.

   File → **Write** → **Case & Data...**

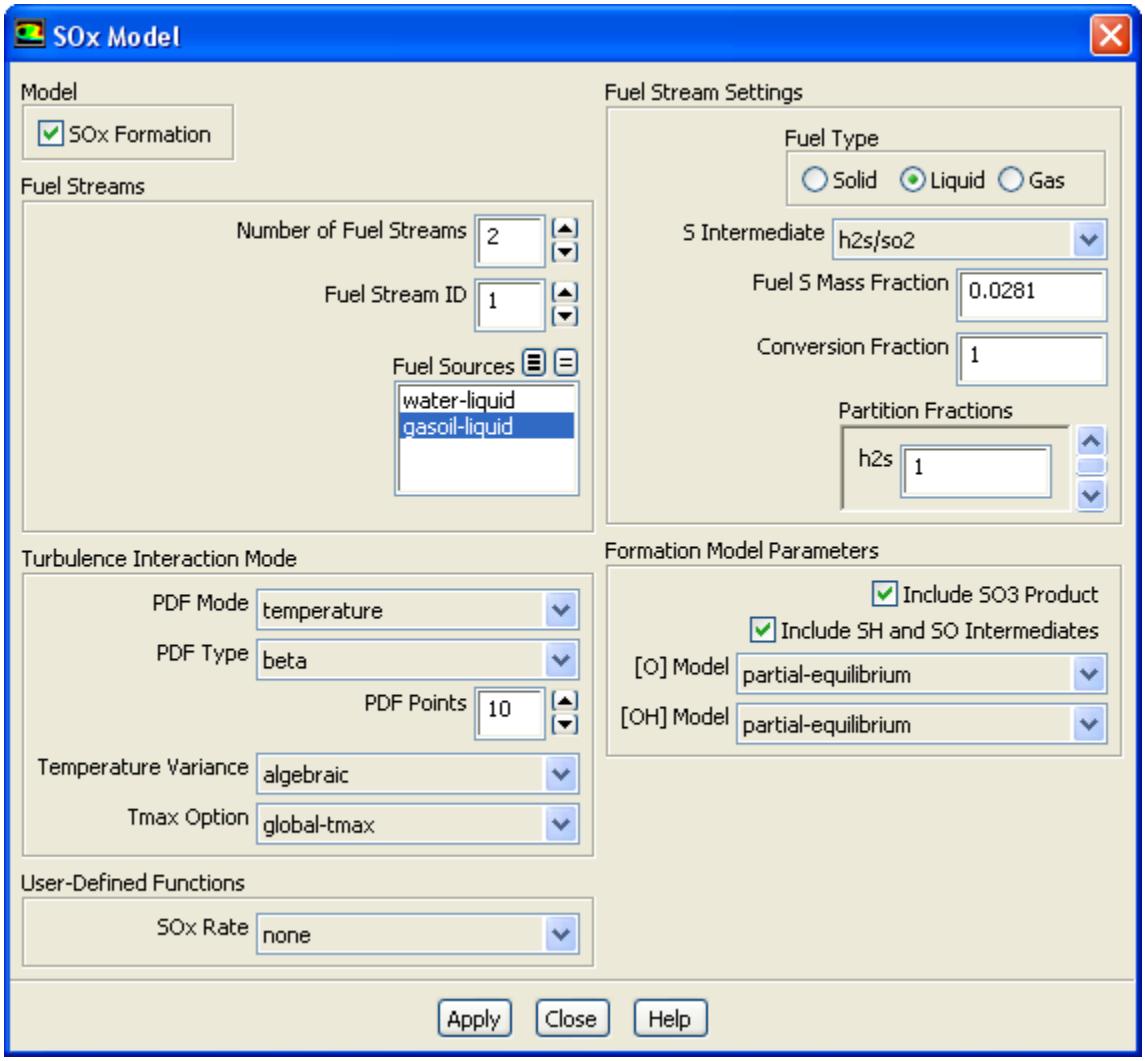
21.2.1.1. Enabling the SOx Model

To model SO_x formation, enable the **SOx Formation** option in the SOx Model Dialog Box (p. 2258) (Figure 21.6: The SOx Model Dialog Box (p. 1173)).

Setup → **Models** → **Species** → **SOx** **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.6: The SOx Model Dialog Box



21.2.1.2. Defining the Fuel Streams

When modeling fuel SO_x formation, ANSYS Fluent allows you to define up to three separate fuel streams, and to select the fuel S sources for each fuel stream.

You can define multiple fuel streams to include in your model with the following configurations:

- Solid and liquid fuels (combusting particle and droplet) both contributing to fuel SO_x.
- Two or three solid fuels with different S-content and SO_2 /H_2S production models (two or three combusting particles), for example coal blends, coal-biomass cofiring, and so on.
- Two or three liquid fuels with different S-content and SO_2 /H_2S production models (two or three droplet or multicomponent particles).
- Gas and solid (or droplet) fuel both contributing to fuel SO_x.

  In addition, you can model one solid fuel contributing to SO_x in the presence of another reacting solid particle not containing any S, by specifying the active S fuel source for SO_x formation. For this configuration, you will not need to define multiple fuel streams in your model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can define multiple fuel streams when you are modeling SO_x formation, as shown in the following steps:

1. Specify the **Number of Fuel Streams** in the **Fuel Streams** group box. You are allowed up to three separate fuel streams.

2. Define the first fuel stream.

   a. Select the fuel stream to be defined by using the arrow keys of the **Fuel Stream ID** field.

   b. Select the **Fuel Type** in the **Fuel Stream Settings** group box.

   c. If your **Fuel Type** is **Liquid** or **Solid**, select the S sources from the **Fuel Sources** list.

      - If the **Fuel Type** is **Solid** and you have defined multiple injections with different combusting particle materials in your reacting flow calculation, the available combusting particle materials will be listed in the **Fuel Sources** list. Select one or more materials from the list to be included as fuel sources in the **SOx** calculation. Your selection will be used to determine the char burnout rate S_c and volatile release rate S_{vol} in Equation 14.124 and Equation 14.125 in the Theory Guide. Make sure to deselect all combusting particle materials that do not contribute to SO_x.

      - If the **Fuel Type** is **Liquid** and you have defined multiple injections with different droplet or multicomponent particle materials in your reacting flow calculation, the available materials will be listed in the **Fuel Sources** list. Select one or more materials from the list to be included as fuel sources in the **SOx** calculation. Your selection will be used to determine the fuel release rate S_{fuel} in Equation 14.123 in the Theory Guide. Make sure to deselect all droplet and multicomponent materials that do not contribute to SO_x.

   d. If the **Fuel Type** in your model is **Gas**, select one or more materials from the **Fuel Species** list. You cannot select more than 5 fuel species for each fuel stream, and the total number of fuel species selected for all the fuel streams combined cannot exceed 10. Your selection will be used to determine the mean limiting reaction rate $\mathcal{R}_{cf}$ in Equation 14.122 in the Theory Guide.

   e. Specify the parameters for this particular fuel stream in the **Fuel Stream Settings** group box. See Defining the SOx Fuel Stream Settings (p. 1175) for details.

3. Repeat steps 2.(a)–2.(e) for each additional fuel stream.

Important

Important considerations should be made when reading case and data files set up in a version of ANSYS Fluent 14.5 or earlier:

- When reading a case and data file with multiple injection materials that was set up in a version of ANSYS Fluent previous to and including 14.5, ANSYS Fluent will initialize the injection material specific fuel S sources for the fuel SO_x model. ANSYS Fluent will perform a DPM iteration when the flow iterations are initiated.

- When reading a case file that was set up in a version older than ANSYS Fluent 14.5 with multiple fuel streams defined for the **SOx** model, you must review the setup and select the S sources from the **Fuel Sources** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

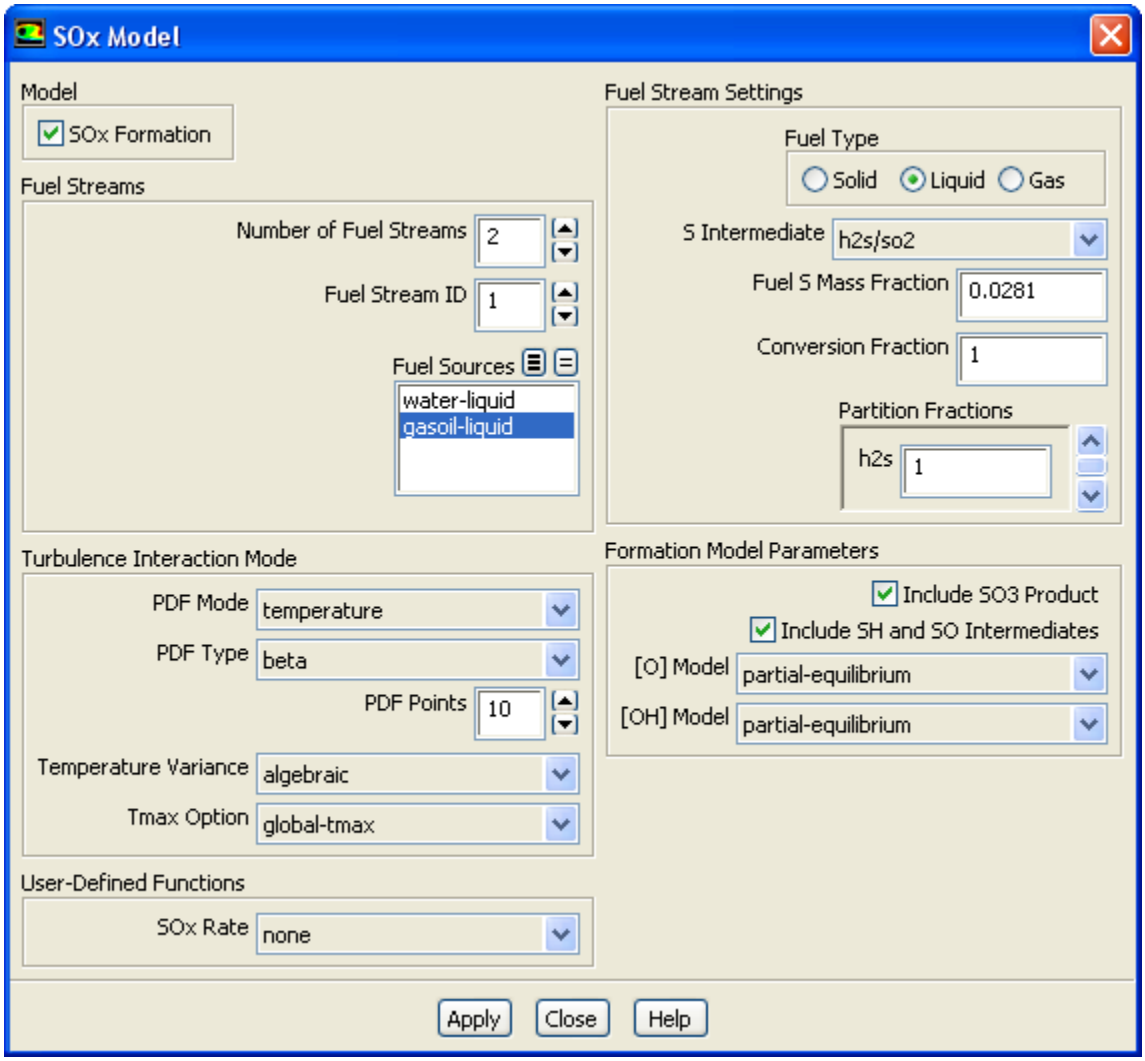
21.2.1.3. Defining the SOx Fuel Stream Settings

When using the SO_x model, you must set the parameters in the **Fuel Stream Settings** group box for each fuel stream specified in the **Fuel Stream ID** field.

To begin, specify the fuel type in the following manner:

- To calculate SO_x formation from a solid fuel, select **Solid** under **Fuel Type**.
- To calculate SO_x formation from a liquid fuel, select **Liquid** under **Fuel Type**.
- To calculate SO_x formation from a gaseous fuel, select **Gas** under **Fuel Type**.

Figure 21.7: The SOx Model Dialog Box Displaying Liquid Fuel Parameters



Note that you can use only one of the fuel types for a given fuel stream. The **Gas** option is available only when the **Species Transport** model is enabled (see Enabling Species Transport and Reactions and Choosing the Mixture Material (p. 960)).

21.2.1.3.1. Setting SOx Parameters for Gaseous and Liquid Fuel Types

If you have selected **Gas** or **Liquid** as the **Fuel Type**, you must specify the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the intermediate species (**h2s**, **so2**, or **h2s/so2**) in the **S Intermediate** drop-down list.
- Set the correct mass fraction of sulfur in the fuel (kg sulfur per kg fuel) in the **Fuel S Mass Fraction** field.
- Specify the overall fraction of the fuel S, by mass, that will be converted to the intermediate species and/or product SO_2 in the **Conversion Fraction** field. Therefore, any remaining S will not contribute to SO_x formation. This is based on the assumption that the remaining volatile S will convert to gas phase sulfur. The **Conversion Fraction** for the **S Intermediate** has a default value of 1.
- If you selected **h2s/so2** as the intermediate, you must set the fraction of the converted fuel S, by mass, that will become **h2s** under **Partition Fractions**. The fraction of fuel S that will become SO_2 will be calculated by the remainder.

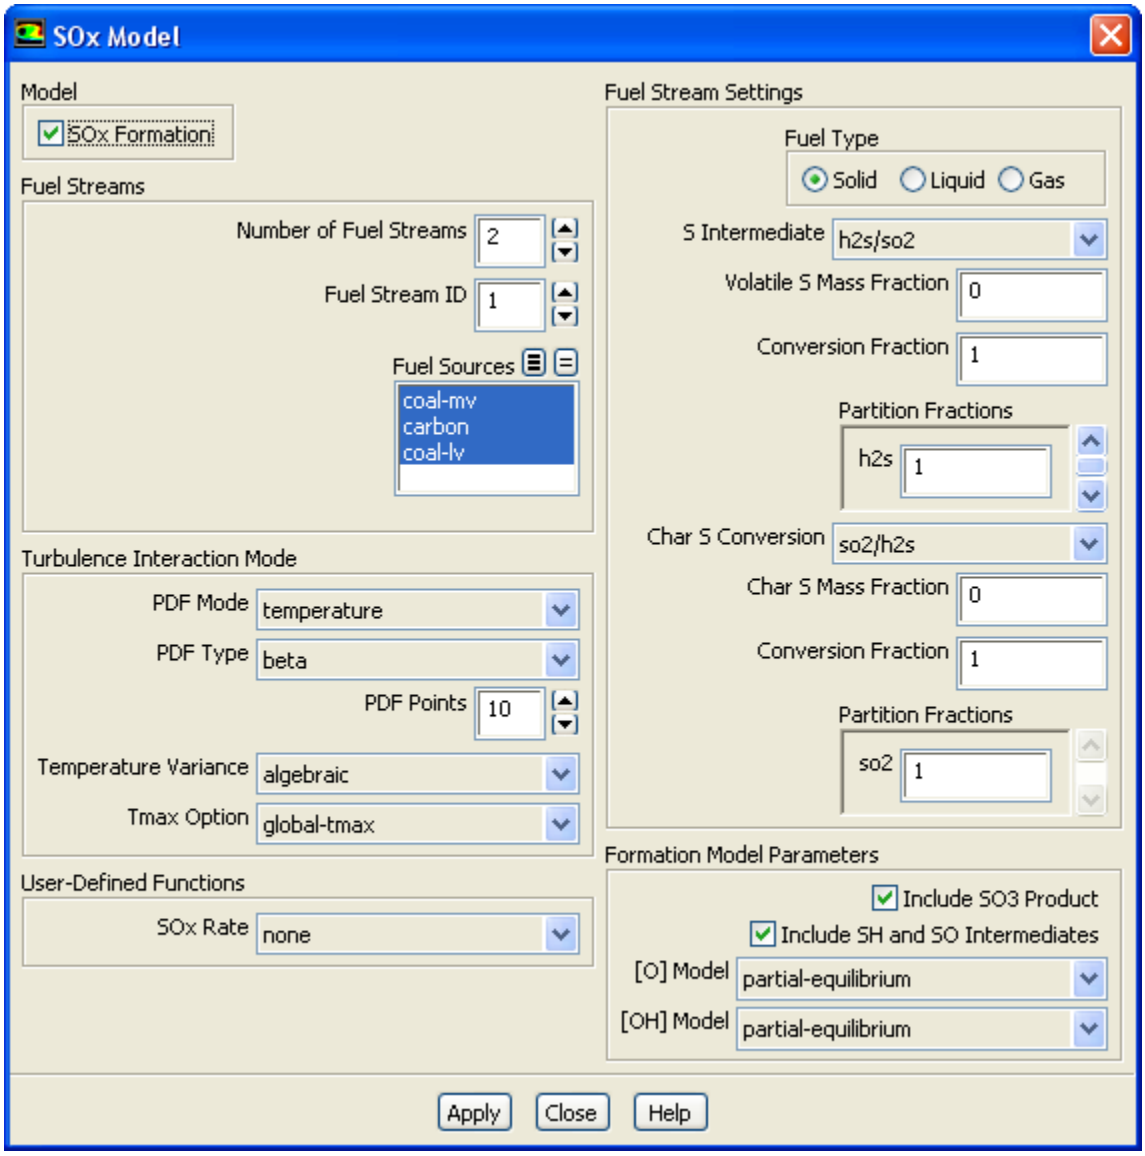
  Note that setting a partition fraction of 0 for H_2S is equivalent to assuming that all fuel S is converted to the final product SO_2.

21.2.1.3.2. Setting SOx Parameters for a Solid Fuel

For solid fuel, several inputs are required for the SO_x model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.8: The SOx Model Dialog Box Displaying Solid Fuel Parameters



- Select the intermediate species (**h2s**, **so2**, or **h2s/so2**) in the **S Intermediate** drop-down list.
- Specify the mass fraction of sulfur in the volatiles in the **Volatile S Mass Fraction** field.
- Specify the overall fraction of the volatile S, by mass, that will be converted to the intermediate species and/or product SO_2 in the **Conversion Fraction** field.
- If you selected **h2s/so2** as the volatile S intermediate, you must specify the fraction of the converted volatile S, by mass, that will become **h2s** under **Partition Fractions**. The fraction of volatile S that will become SO_2 will be calculated by the remainder.
- Select the char S conversion path from the **Char S Conversion** drop-down list as **so2**, **h2s**, or **so2/h2s**.
- Specify the mass fraction of sulfur in the char in the **Char S Mass Fraction** field.
- Specify the overall fraction of the char S, by mass, that will be converted to the intermediate species and/or product SO_2 in the **Conversion Fraction** field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you selected **so2/h2s** from the **Char S Conversion** drop-down list, you must specify the fraction of the converted char S, by mass, that will become SO_2 under **Partition Fractions**. The fraction of char S that will become H_2S will be calculated by the remainder.

The following equations are used to determine the mass fraction of sulfur in the volatiles and char:

$$\dot{m}_{S_{v/c}} = \dot{m}_{v/c} * mf_{S_{v/c}} \tag{21.8}$$

where

$\dot{m}_{S_{v/c}}$ = rate of release of fuel sulfur in kg/s

$\dot{m}_{v/c}$ = rate of release of volatiles (v) or char (c) in kg/s

$mf_{S_{v/c}}$ = mass fraction of sulfur in volatiles or char

Let

TS_{fuel} = total sulfur mass fraction in daf coal (that is, from daf ultimate analysis)

S_{split} = char sulfur as a fraction of total sulfur

F_{vol} = mass fraction of volatiles in daf coal

F_{char} = mass fraction of char in daf coal

Then the following should hold:

$$F_{vol} + F_{char} = 1 \tag{21.9}$$

$$\frac{F_{char} * mf_{S_c}}{TS_{fuel}} = S_{split} \tag{21.10}$$

$$F_{vol} * mf_{S_v} + F_{char} * mf_{S_c} = TS_{fuel} \tag{21.11}$$

$$mf_{S_v} = \left(1 - S_{split}\right) * \frac{TS_{fuel}}{F_{vol}} \tag{21.12}$$

$$mf_{S_c} = S_{split} * \frac{TS_{fuel}}{F_{char}} \tag{21.13}$$

21.2.1.4. Defining the SOx Formation Model Parameters

You can set the SO_x formation model parameters that apply to all of the fuel streams in the **Formation Model Parameters** group box:

- You have the option of including SO_3 as a product, and including SH and SO as intermediates by enabling the **Include SO3 Product** and the **Include SH and SO Intermediates** options, respectively. See Reaction Mechanisms for Sulfur Oxidation in the Theory Guide for further information.

- Specify the method by which O and OH will be calculated. The SO_x routines employ three methods for reduction calculations of SO_x:

  – You can select **equilibrium**, **partial-equilibrium**, or **instantaneous** in the **[O] Model** drop-down list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– You can select **none**, **partial-equilibrium**, or **instantaneous** in the **[OH] Model** drop-down list.

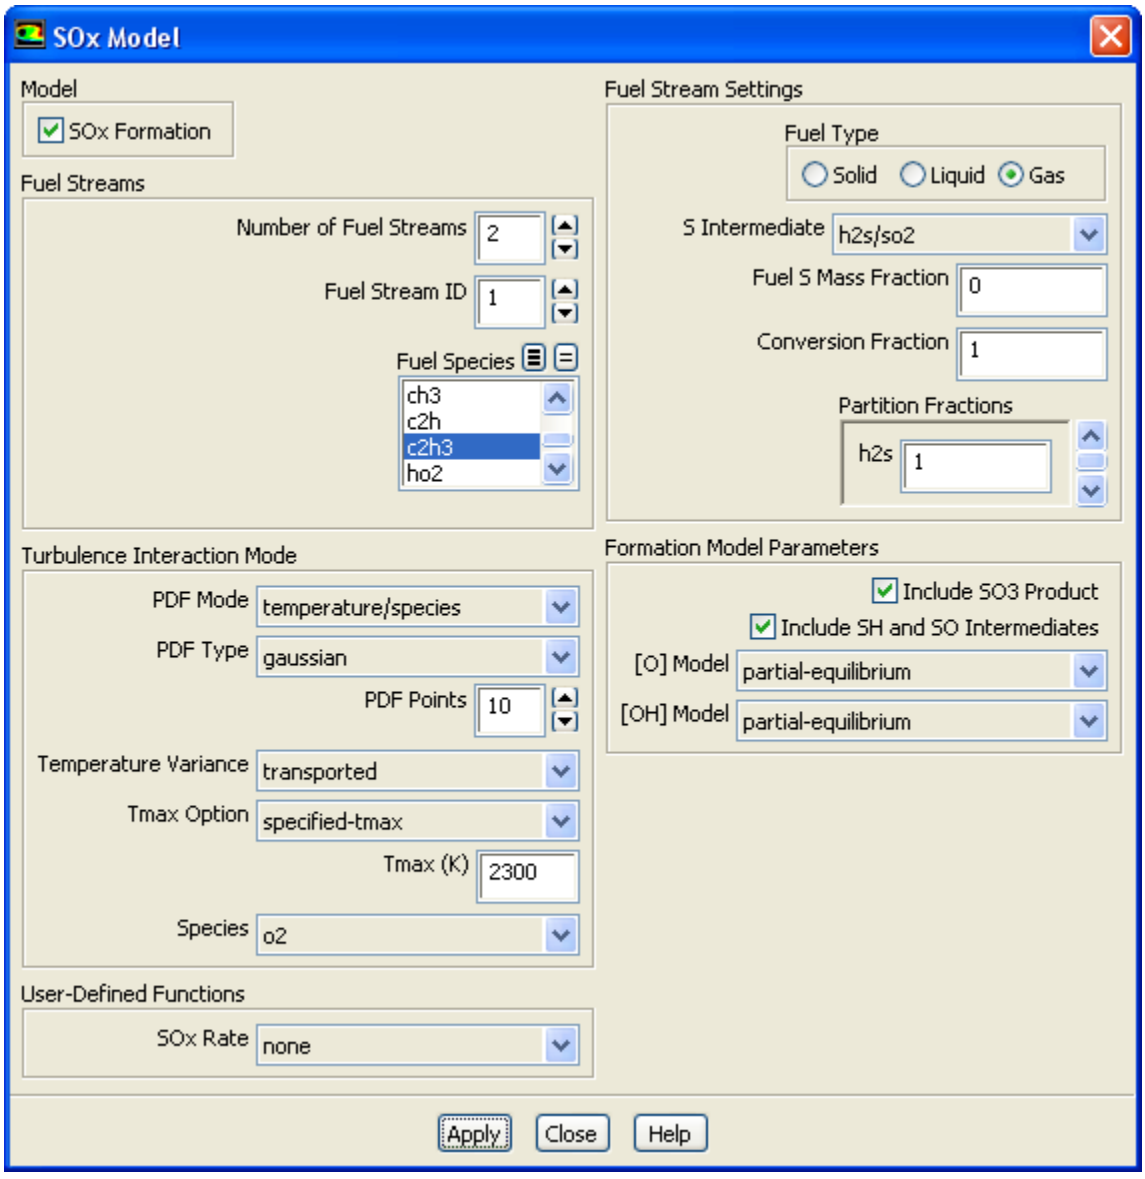
Important

To use the predicted O and/or OH concentration, select **instantaneous** in the **[O] Model** or **[OH] Model** drop-down list.

21.2.1.5. Setting Turbulence Parameters

If you want to take into account turbulent fluctuations when you compute the specified SO_2 formation, define the turbulence parameters in the **Turbulence Interaction Mode** group box.

Figure 21.9: The SOx Model Dialog Box for a Gas Fuel Type with Turbulence



Select one of the options in the **PDF Mode** drop-down list:

- Select **temperature** to take into account fluctuations of temperature.

- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s).

Important

When modeling the formation of other pollutants along with SO_x, you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** tab of the NOx Model Dialog Box (p. 2250) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially premixed combustion model to model the reacting system. If you use the **mixture fraction** option, the instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous SO_x rates are calculated at each cell. The PDF used for convoluting the instantaneous SO_x rates is the same as the one used to compute the mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF for mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous SO_x rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** group box:

PDF Type

allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using Equation 14.108 in the Theory Guide. If you select **gaussian**, the PDF will be modeled using Equation 14.111 in the Theory Guide.

PDF Points

allows you to specify the number of points used to integrate the beta or Gaussian function in Equation 14.105 or Equation 14.106 in the Theory Guide on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (for example, 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance

allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see Equation 14.114 in the Theory Guide). You have the option of selecting **transported** to instead solve Equation 14.113 in the Theory Guide. Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option

provides various options for determining the maximum limit of the temperature used for the integration of the PDF (see Equation 8.43 in the *Fluent Theory Guide*) to calculate mean rates for turbulent fluctuations of SO_x:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field.
- You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**.
- You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**.
- If you have selected a user-defined function from the **SOx Rate** drop-down menu in the **User-Defined Functions** group box, then you can select **user-defined** so that the limit is specified by a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

Species

only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the SO_x formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation (Equation 14.114 in the Theory Guide).

21.2.1.6. Specifying a User-Defined Function for the SOx Rate

You can choose to specify a user-defined function for the rate of SO_x production. By default, the rate returned from the user-defined function is added to the rate returned from the standard SO_x production options. You also have the option of replacing ANSYS Fluent's SO_x rate calculations with your own user-defined SO_x rate.

In addition to or instead of using the UDF to specify the SO_x rate, you can use it to specify custom values for the maximum limit (T_{max}) that is used for the integration of the temperature PDF (when temperature is accounted for in the turbulence interaction modeling).

To use a UDF to add a rate to ANSYS Fluent's SO_x rate calculations, you must compile and load the desired function, and then select it from the **SOx Rate** drop-down list in the **User-Defined Functions** group box. After you have selected the UDF, you have the following options:

- You can specify that your custom rate is added to the ANSYS Fluent SO_x rate calculations, by retaining the default selection of **Add to the Fluent Rate** in the **UDF Rate** group box.
- You can replace the ANSYS Fluent SO_x rate calculations with your custom rate, by selecting **Replace Fluent Rate** in the **UDF Rate** group box.
- You can specify custom values for T_{max}, by selecting **user-defined** from the **Tmax Option** drop-down list in the **Turbulence Interaction Mode** group box.

See the Fluent Customization Manual for details about user-defined functions.

21.2.1.7. Defining Boundary Conditions for the SOx Model

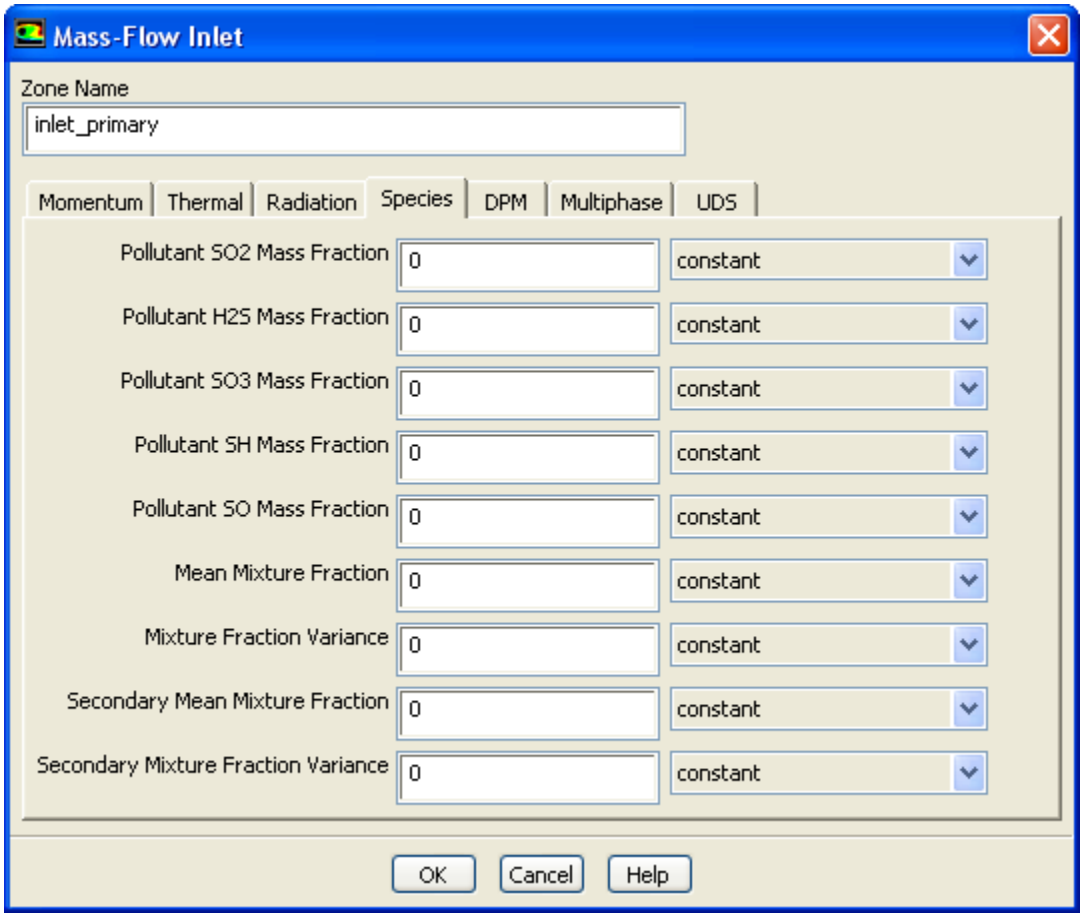
At flow inlet boundaries, you must specify the **Pollutant SO Mass Fraction**, and if necessary, the **Pollutant SH Mass Fraction**, **Pollutant H2S Mass Fraction**, **Pollutant SO3 Mass Fraction**, and **Pollutant SO2 Mass Fraction** in the **Species** tab, as demonstrated in Figure 21.10: The Mass-Flow Inlet Dialog Box and the **Species** Tab (p. 1182).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Boundary Conditions

You can retain the default inlet values of zero for these quantities or you can enter nonzero numbers as appropriate for your combustion system.

Figure 21.10: The Mass-Flow Inlet Dialog Box and theSpecies Tab



21.2.2. Solution Strategies

To solve for SO_x products:

- (optional) If the discrete phase model (DPM) is turned on (by enabling the **Interaction with Continuous Phase**) to run with the SO_x model, then set the **DPM Iteration Interval** to `0` such that no DPM iterations are performed as the SO_x case is being solved.
- In the Equations Dialog Box (p. 2511) of the Solution Controls Task Page (p. 2508), turn off the solution of all variables except **Pollutant so2** and **Pollutanth2s** (and **Pollutant so3**, **Pollutant sh**, and **Pollutant so**, if applicable).

  Solution → Controls → Equations...
- In the Solution Controls Task Page (p. 2508), set suitable values for the pollutant SO_2 and H_2S (and SO_3, SH, and SO, if applicable) under-relaxation factors. A value of 1.0 is suggested, although lower values may be required for certain problems. That is, if convergence cannot be obtained, try a lower under-relaxation value.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → **Controls**

- Under **Spatial Discretization** in the Solution Methods Task Page (p. 2504), select the desired scheme for each of the pollutants, SO_2 and H_2S (and SO_3, SH, and SO, if applicable)

Solution → **Methods**

- In the Residual Monitors Dialog Box (p. 2789), decrease the convergence criterion for the pollutants SO_2 and H_2S (and SO_3, SH, and SO, if applicable) to 10^{-6}.

Solution → **Monitors** → **Residuals** **Edit...**

- Perform calculations until convergence (that is, until the SO_2 and H_2S—and SO_3, SH, and SO—pollutant residuals are below 10^{-6}) to ensure that the SO_2 and H_2S (and SO_3, SH, and SO) concentration fields are no longer evolving.

Solution → **Run Calculation**

- Review the mass fractions of pollutants, SO_2 and H_2S (and SO_3, SH, and SO), by generating graphical plots or alphanumeric reports as described in Postprocessing (p. 1183).

21.2.3. Postprocessing

When you compute SO_x formation, the following additional variables will be available for postprocessing. They are contained in the **SOx...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

- **Mass fraction of pollutant so2**
- **Mass fraction of pollutant h2s**
- **Mass fraction of pollutant so3**
- **Mass fraction of pollutant sh**
- **Mass fraction of pollutant so**
- **Mole fraction of pollutant so2**
- **Mole fraction of pollutant h2s**
- **Mole fraction of pollutant so3**
- **Mole fraction of pollutant sh**
- **Mole fraction of pollutant so**
- **so2 Density**
- **h2s Density**
- **so3 Density**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **sh Density**
- **so Density**
- **Rate of so2**
- **Rate of h2s**
- **Rate of so3**
- **Rate of sh**
- **Rate of so**

21.3. Soot Formation

This section contains information about using the soot formation models in ANSYS Fluent. For information about the theory behind the soot models in ANSYS Fluent, see Soot Formation in the Theory Guide.

21.3.1. Using the Soot Models

21.3.1. Using the Soot Models

When the mass fraction of soot is relatively large (for example, 10%) or if your problem involves the effect of radiation, the soot formation should be computed as part of the main combustion solution and not through postprocessing (as is done for the NO_x and SO_x models). The procedure for setting up and solving a soot formation model is outlined below, and described in detail on the pages that follow. Remember that only the steps that are pertinent to soot modeling are shown here. For information about inputs related to other models that you are using in conjunction with the soot formation model, see the appropriate sections for those models.

1. Set up your combustion problem using ANSYS Fluent as usual. Note the following limitations:
   - None of the soot models are compatible with premixed combustion.
   - The one-step and two-step soot formation models are only available for turbulent flows.
2. Enable the desired soot formation model and set the related parameters, as described in this section.

   Setup → **Models** → **Species** → **Soot** **Edit...**
3. Define the boundary conditions for soot (and nuclei, if you are not using the one-step model) at flow inlets.

   Setup → **Boundary Conditions**
4. In the Solution Controls Task Page (p. 2508), set a suitable value for the soot (and nuclei, if you are not using the one-step model) under-relaxation factor(s). The default value is 0.9. If convergence cannot be obtained with this value, try a lower under-relaxation value.

   Solution → **Controls**
5. Perform calculations until convergence (that is, until the soot / nuclei residual is below 10^{-6}) to ensure that the soot (and nuclei) field is no longer evolving.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → **Run Calculation**

Note that when **Soot-Radiation Interaction** is enabled in the **Soot Model** dialog box, soot equations (soot, nuclei, and tar species, if available) must be solved together with the combustion solution to obtain correct radiation coupling. Therefore, when **Soot-Radiation Interaction** is enabled, the soot equations are not available for pollutant postprocessing, but will be solved together with the combustion solution. However, if other pollutants are to be solved (while soot/radiation interaction is enabled), those pollutant equations can be postprocessed.

6. Review the mass fraction of soot (and nuclei) by generating graphical plots or alphanumeric reports in the usual way.

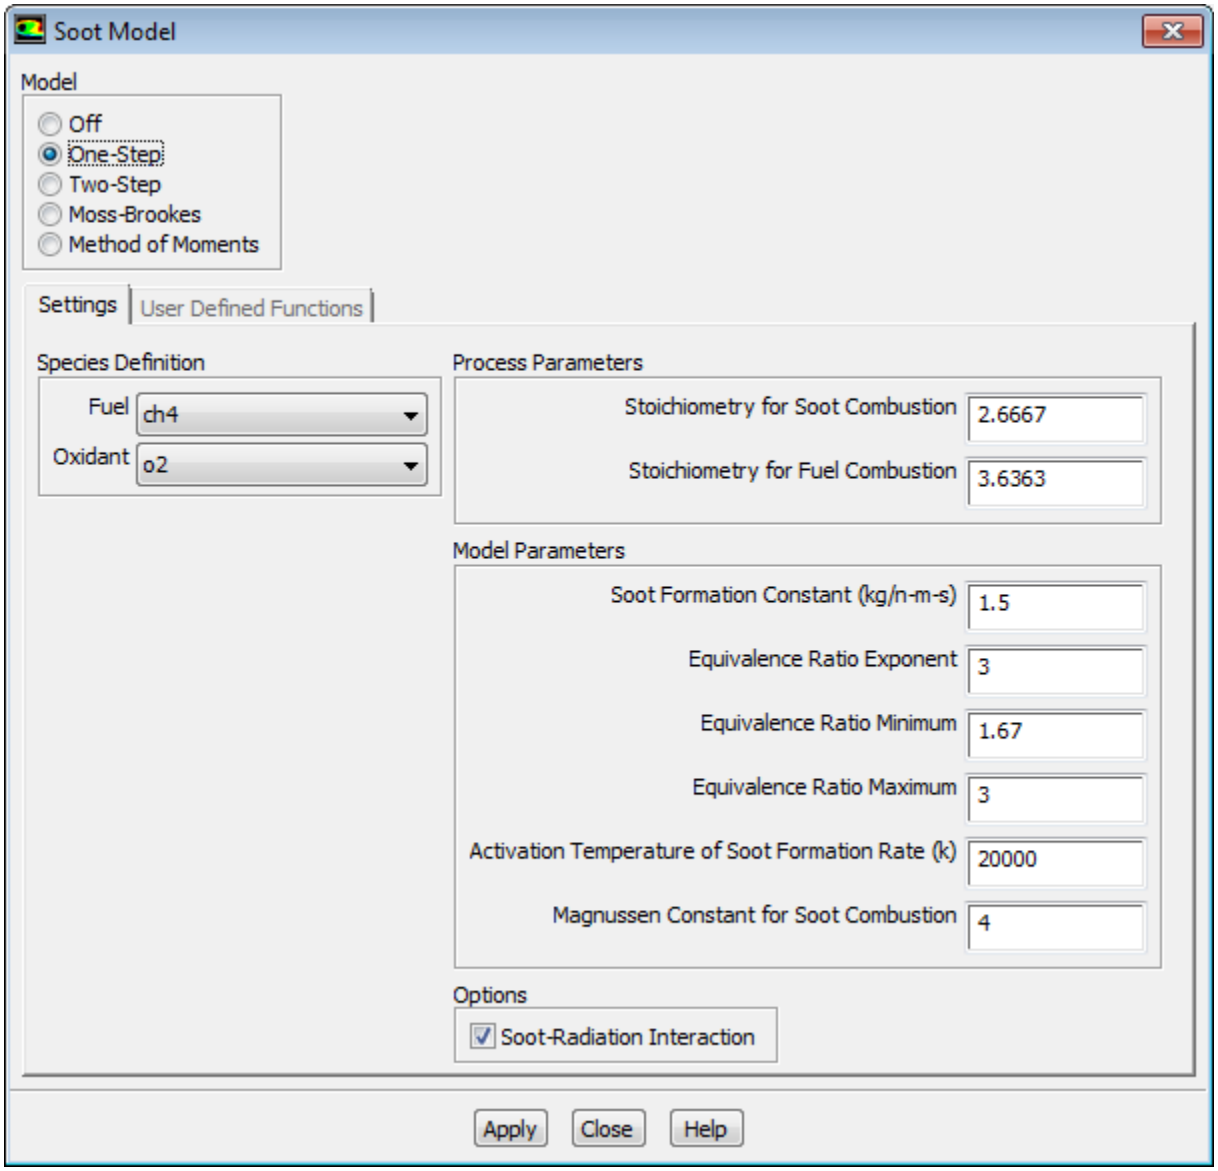
7. Save a new set of case and data files, if desired.

21.3.1.1. Setting Up the One-Step Model

You can enable and set up the one-step soot formation model by using the Soot Model Dialog Box (p. 2262) (Figure 21.11: The Soot Model Dialog Box for the One-Step Model (p. 1186)).

Setup → **Models** → **Species** → **Soot** **Edit...**

Figure 21.11: The Soot Model Dialog Box for the One-Step Model



Under **Model**, select **One-Step**. The dialog box will expand to show the appropriate inputs.

Next, you must tell ANSYS Fluent which chemical species in your model should be used as the fuel and oxidizer. Under **Species Definition**, select the fuel in the **Fuel** drop-down list and the oxidizer in the **Oxidant** drop-down list. If you are using the non-premixed model for the combustion calculation and your fuel stream consists of a mixture of components, you should choose the most appropriate species as the **Fuel** species for the soot formation model. Similarly, the most significant oxidizing component (for example, O_2) should be selected as the **Oxidant**.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see The Effect of Soot on the Absorption Coefficient in the Theory Guide.

You must next define the **Process Parameters**, by specifying the stoichiometry of the fuel and soot combustion for the one-step model:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Stoichiometry for Soot Combustion
is the mass stoichiometry, ν_{soot}, in Equation 14.131 in the Theory Guide, which computes the soot combustion rate. The default value supplied by ANSYS Fluent (2.6667) assumes that the soot is pure carbon and that the oxidizer is O_2.

Stoichiometry for Fuel Combustion
is the mass stoichiometry, ν_{fuel}, in Equation 14.131 in the Theory Guide, which computes the soot combustion rate. The default value supplied by ANSYS Fluent (3.6363) is for combustion of propane ($C_3 H_8$) by oxygen (O_2).

You must then set the **Modeling Parameters** that are used in Equation 14.128, Equation 14.130, and Equation 14.131 in the Theory Guide:

Soot Formation Constant
is the parameter C_s in Equation 14.128 in the Theory Guide.

Equivalence Ratio Exponent
is the exponent r in Equation 14.128 in the Theory Guide.

Equivalence Ratio Minimum
and **Equivalence Ratio Maximum** are the minimum and maximum values of the fuel equivalence ratio ϕ in Equation 14.128 in the Theory Guide. This equation will be solved only if **Equivalence Ratio Minimum** $<\phi<$ **Equivalence Ratio Maximum**; if ϕ is outside of this range, there is no soot formation.

Activation Temperature of Soot Formation Rate
is the term E / R in Equation 14.128 in the Theory Guide.

Magnussen Constant for Soot Combustion
is the constant A used in the rate expressions governing the soot combustion rate (Equation 14.130 and Equation 14.131 in the Theory Guide).

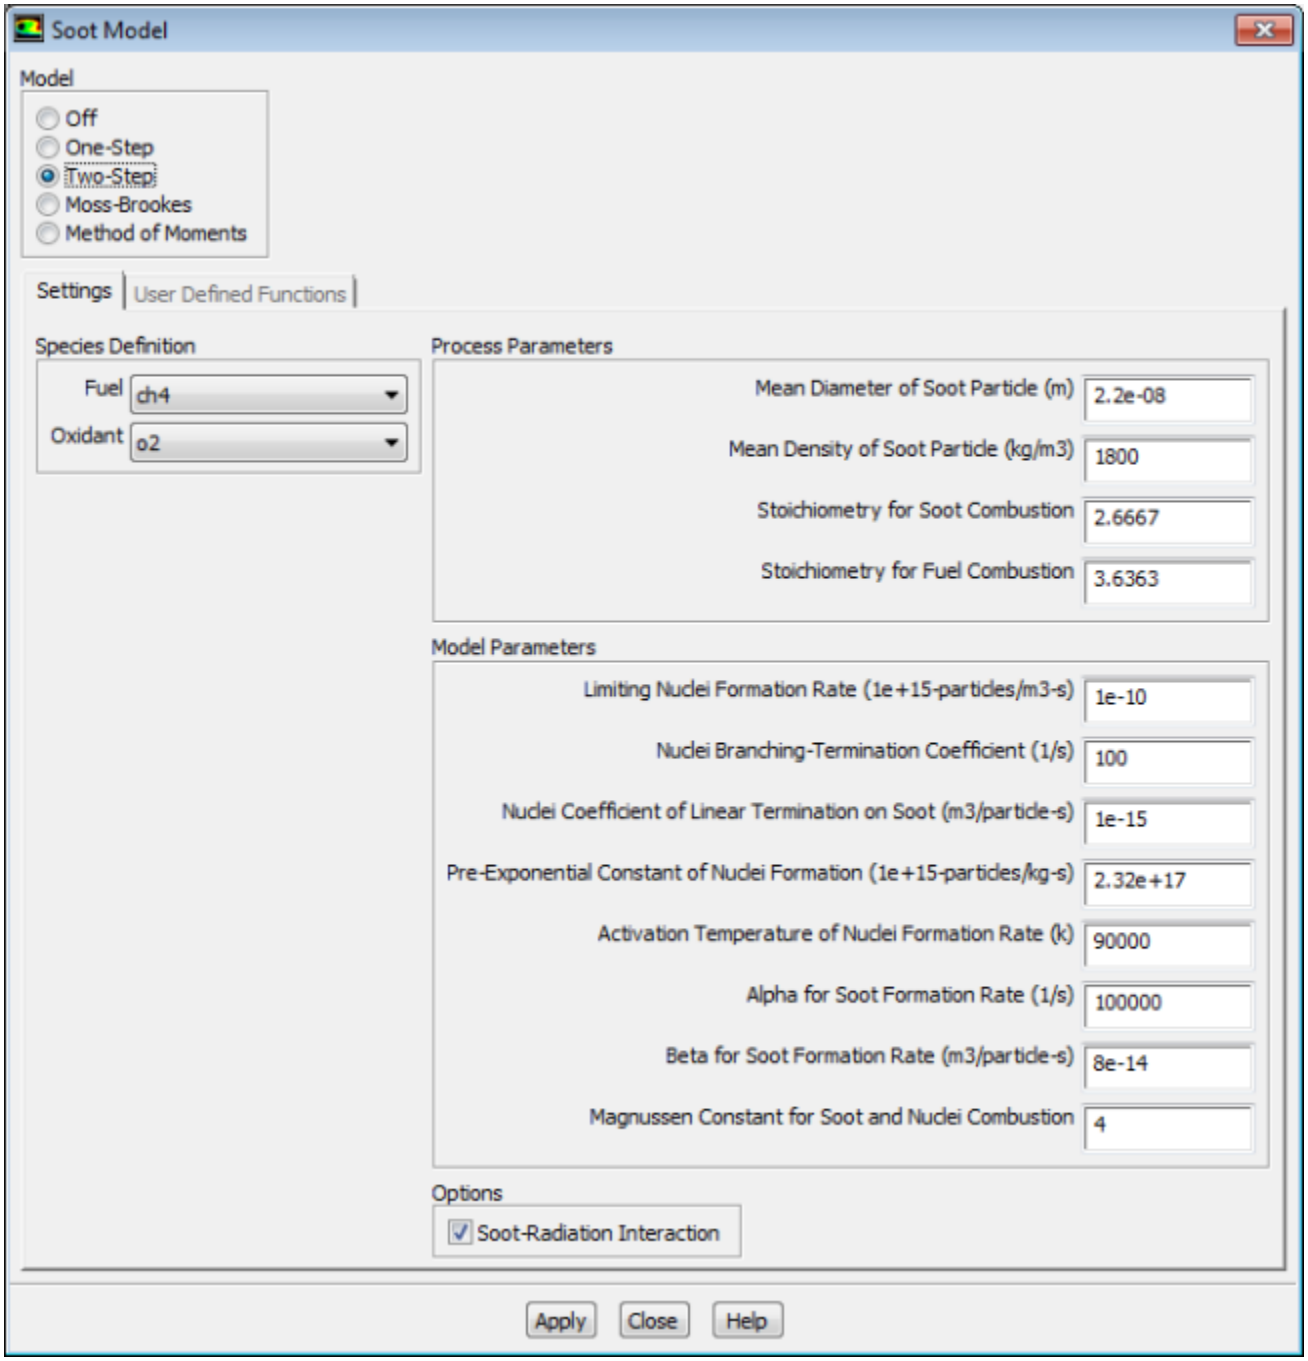
Note that the default values for these parameters are for propane fuel [21] (p. 2888), [126] (p. 2893), and are considered to be valid for a wide range of hydrocarbon fuels.

21.3.1.2. Setting Up the Two-Step Model

You can enable and set up the two-step soot formation model by using the Soot Model Dialog Box (p. 2262) (Figure 21.12: The Soot Model Dialog Box for the Two-Step Model (p. 1188)).

Setup → Models → Species → Soot → Edit...

Figure 21.12: The Soot Model Dialog Box for the Two-Step Model



Under **Model**, select **Two-Step**. The dialog box will expand to show the appropriate inputs.

Important

Note that the two-step Tesner model should only be used when the eddy-dissipation model is used to define the turbulence-chemistry interaction.

Next, you must tell ANSYS Fluent which chemical species in your model should be used as the fuel and oxidizer. Under **Species Definition**, select the fuel in the **Fuel** drop-down list and the oxidizer in the **Oxidant** drop-down list. If you are using the non-premixed model for the combustion calculation and your fuel stream consists of a mixture of components, you should choose the most appropriate species

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

as the **Fuel** species for the soot formation model. Similarly, the most significant oxidizing component (for example, O_2) should be selected as the **Oxidant**.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see The Effect of Soot on the Absorption Coefficient in the Theory Guide.

You must next define the **Process Parameters**, by specifying the stoichiometry of the fuel and soot combustion, as well as the average size and density of the soot particles, for the two-step model:

Mean Diameter of Soot Particle

and **Mean Density of Soot Particle** are the assumed average diameter and average density of the soot particles in the combustion system, used to compute the soot particle mass, m_p, in Equation 14.134 in the Theory Guide for the two-step model. Note that the default values for soot density and diameter are taken from [64] (p. 2890).

Stoichiometry for Soot Combustion

is the mass stoichiometry, ν_{soot}, in Equation 14.131 in the Theory Guide, which computes the soot combustion rate. The default value supplied by ANSYS Fluent (2.6667) assumes that the soot is pure carbon and that the oxidizer is O_2.

Stoichiometry for Fuel Combustion

is the mass stoichiometry, ν_{fuel}, in Equation 14.131 in the Theory Guide, which computes the soot combustion rate. The default value supplied by ANSYS Fluent (3.6363) is for combustion of propane ($C_3 H_8$) by oxygen (O_2).

You must then set the **Modeling Parameters** that are used in Equation 14.130, Equation 14.131, Equation 14.134, Equation 14.136, and Equation 14.137 in the Theory Guide:

Limiting Nuclei Formation Rate

is the limiting value of the kinetic nuclei formation rate, η_0 in Equation 14.137 in the Theory Guide. Below this limiting value, the branching and termination term, $(f-g)$ in Equation 14.136 in the Theory Guide, is not included.

Nuclei Branching-Termination Coefficient

is the term $\left(f-g\right)$ in Equation 14.136 in the Theory Guide.

Nuclei Coefficient of Linear Termination on Soot

is the term g_0 in Equation 14.136 in the Theory Guide.

Pre-Exponential Constant of Nuclei Formation

is the pre-exponential term a_0 in the kinetic nuclei formation term, Equation 14.137 in the Theory Guide.

Activation Temperature of Nuclei Formation Rate

is the term E/R in the kinetic nuclei formation term, Equation 14.137 in the Theory Guide.

Alpha for Soot Formation Rate

is α, the constant in the soot formation rate equation, Equation 14.134 in the Theory Guide.

Beta for Soot Formation Rate

is β, the constant in the soot formation rate equation, Equation 14.134 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Magnussen Constant for Soot and Nuclei Combustion
is the constant A used in the rate expressions governing the soot combustion rate (Equation 14.130 and Equation 14.131 in the Theory Guide).

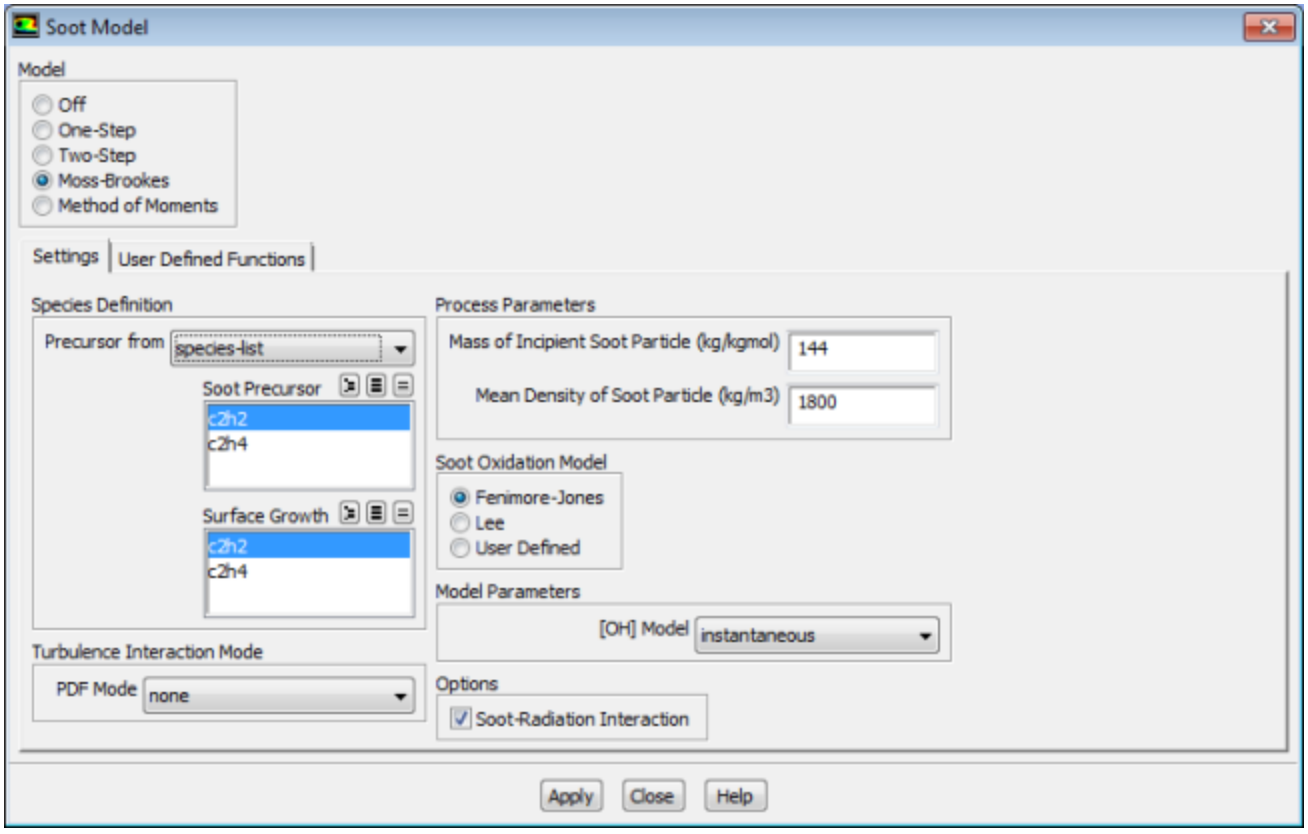
The default values for the two-step model are the same as in Magnussen and Hjertager [64] (p. 2890) (for an acetylene flame), except for a_0, which is assumed to have the original value from Tesner et al. [122] (p. 2893). If your model involves propane fuel rather that acetylene, it is recommended that you change the value of α to 3.5×10^8 [5] (p. 2887). For best results, you should modify both of these parameters, using empirically determined inputs for your specific combustion system.

21.3.1.3. Setting Up the Moss-Brookes Model and the Hall Extension

You can enable and set up the Moss-Brookes and Moss-Brookes-Hall soot formation models by using the Soot Model Dialog Box (p. 2262) (Figure 21.13: The Soot Model Dialog Box for the Moss-Brookes Model (p. 1190)).

Setup → Models → Species → Soot Edit...

Figure 21.13: The Soot Model Dialog Box for the Moss-Brookes Model



Under **Model**, select **Moss-Brookes** or **Moss-Brookes-Hall**. The dialog box will expand to show the appropriate inputs. Note the following about these models:

- The **Moss-Brookes** model was originally proposed for soot prediction in methane flames. However, it can be equally applicable to higher hydrocarbon species by appropriately modifying the soot precursor and participating surface growth species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The **Moss-Brookes-Hall** model is applicable for higher hydrocarbon fuels (for example, kerosene) and will only be available when C_2H_2, C_6H_6, C_6H_5, and H_2 are present in the gas phase species list.

You must next define the precursor species in the **Species Definition** group box. When suitable precursor species are present in the species list, you can select **species-list** from the **Precursor from** drop-down list, and then select the **Soot Precursor** species and the **Surface Growth** species from the selection lists. Note that for the **Moss-Brookes** model, you can select acetylene (**c2h2**), ethylene (**c2h4**), and/or benzene (**c6h6**) for the **Soot Precursor**; if neither are present or if you would like to specify a different precursor correlation, then curve fitting will be used to determine the precursor and surface growth species mass fractions (see Species Definition for the Moss-Brookes Model with a User-Defined Precursor Correlation (p. 1194) for further details regarding curve fitting).

Next, specify how turbulent fluctuations will be accounted for in the soot formation calculations, by defining the turbulence parameters in the **Turbulence Interaction Mode** group box.

Select one of the options in the **PDF Mode** drop-down list:

- Select **none** to ignore turbulence and use laminar soot rate calculations.
- Select **temperature** to take into account fluctuations of temperature.
- Select **temperature/species** to take into account fluctuations of temperature and mass fraction of the species selected in the **Species** drop-down list (which appears when you select this option).
- (non-premixed and partially premixed combustion calculations only) Select **mixture fraction** to take into account fluctuation in the mixture fraction(s). This is the recommended approach, as it generally yields the best results and accuracy.

Important

When modeling the formation of other pollutants along with soot, you should compare the selections made in the **PDF Mode** drop-down lists in the **Turbulence Interaction Mode** tab of the NOx Model Dialog Box (p. 2250) and the **Turbulence Interaction Mode** group boxes of the **SOx Model** and **Soot Model** dialog boxes. If **mixture fraction** is selected in any of these dialog boxes, then it must be selected in all of the others as well.

The **mixture fraction** option is available only if you are using either the non-premixed or partially premixed combustion model to model the reacting system. If you use the **mixture fraction** option, the instantaneous temperatures and species concentrations are taken from the PDF look-up table as a function of mixture fraction and enthalpy and the instantaneous soot production rates are calculated at each cell. The PDF used for convoluting the instantaneous soot rates is the same as the one used to compute the mean flow-field properties. For example, for single-mixture fraction models the beta PDF is used, and for two-mixture fraction models, the beta or the double delta PDF can be used. The PDF in terms of mixture fraction is calculated from the values of mean mixture fraction and variance at each cell, and the instantaneous soot rates are convoluted with the mixture fraction PDF to yield the mean rates in turbulent flow.

Note

When `mixture fraction` is selected as **PDF mode**, ANSYS Fluent calculates and tabulates the soot rates apriori for faster computations of soot rates. The soot rates are tabulated at the first soot iteration and a message

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Performing Pollutant PDF integrations...
```

is displayed in the Fluent console.

If you selected **temperature** or **temperature/species** for the **PDF Mode**, you should define the following parameters in the **Turbulence Interaction Mode** group box:

PDF Type
allows you to specify the shape of the PDF, which is then integrated to obtain mean rates for the temperature and (if you selected **temperature/species** for the **PDF Mode**) the species. If you select **beta**, the PDF will be modeled using Equation 14.108 in the Theory Guide. If you select **gaussian**, the PDF will be modeled using Equation 14.111 in the Theory Guide.

PDF Points
allows you to specify the number of points used to integrate the beta or Gaussian function in Equation 14.105 or Equation 14.106 in the Theory Guide on a histogram basis. The default value of 10 is a minimum value. It is recommended that you run the calculation with this minimum value to convergence, and then keep increasing the value (for example, 20–25) until the pollutants of interest stop changing. Increasing this value may improve accuracy, but will also increase the computation time.

Temperature Variance
allows you to specify the form of transport equation that is solved to calculate the temperature variance. The default selection is **algebraic**, which is an approximate form of the transport equation (see Equation 14.114 of the Theory Guide). You have the option of selecting **transported** to instead solve Equation 14.113 in the Theory Guide. Though the **transported** form is more exact, it is also more expensive computationally.

Tmax Option
provides various options for determining the maximum limit of the temperature used for the integration of the PDF (see Equation 8.43 in the *Fluent Theory Guide*) to calculate mean rates for turbulent fluctuations of soot. The default selection is **global-tmax**, which sets the limit as the maximum temperature in the flow field. You can select **local-tmax** if you would rather obtain cell-based maximum temperature limits by multiplying the local cell mean temperature by the value entered in **Tmax Factor**. You can select **specified-tmax** to set the limit for each cell to be the value entered in **Tmax**. Finally, if you have compiled a user-defined function for the soot rate and loaded the library into ANSYS Fluent, then you can select **user-defined** so that the limit is specified by a user-defined function.

Species
only appears if you have selected **temperature/species** for the **PDF Mode**. Your selection in this drop-down menu determines which species' mass fraction is included in the soot formation calculations.

Important

Note that the species variance will always be calculated using the algebraic form of the transport equation (Equation 14.114 in the Theory Guide).

Under **Process Parameters**, you must enter information about the mass and mean density of the soot particles:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mass of Incipient Soot Particles
is M_P in Equation 14.142 and Equation 14.144 in the Theory Guide. Note that this value was assumed to be 144 kg/kmol (12 carbon atoms) in the work of Brookes and Moss, whereas the Hall extension model assumed it to be 1200 kg/kmol (100 carbon atoms).

Mean Density of Soot Particle
is ρ_{soot} in Equation 14.141 in the Theory Guide and ρ in Equation 14.144 in the Theory Guide. Note that this value was assumed to be 1800 kg/m^3 in the work of Brookes and Moss [18] (p. 2887), whereas Hall et al. [40] (p. 2889) assumed it to be 2000 kg/m^3.

Next, you must select the **Soot Oxidation Model**. Your choices include the **Fenimore-Jones** model, as originally used in Brookes and Moss' work, or the **Lee** extended model. The **Lee** model will model soot oxidation due to hydroxyl radicals as in the **Fenimore-Jones** model, as well as the oxidation due to molecular oxygen.

You must then set the **Modeling Parameters**:

[OH] Model
allows you to specify the method by which the OH radical concentration is calculated. The recommended selection from the drop-down list is **instantaneous**, although this option is only available when OH is available in the species list and is calculated by the combustion model. The other option is the **partial-equilibrium** model, which necessitates the availability of $[\mathrm{O}]$ atom concentration within the field.

[O] Model
must be defined when you have selected **partial-equilibrium** for the **[OH] Model**, and specifies the method by which the O radical concentration is calculated. The options include **equilibrium**, **partial-equilibrium**, and **instantaneous**.

Note that in ANSYS Fluent, the oxidation rate scaling parameter (C_{oxid} in Equation 14.142 in the Theory Guide) is set to unity. If you would like to change the value of this parameter, you can use the `define/models/soot-parameters` text command. A lower value will reduce the amount of soot oxidation.

If you want to include the effects of soot formation on the radiation absorption coefficient, enable **Soot-Radiation Interaction** in the **Options** group box. For more details, see The Effect of Soot on the Absorption Coefficient in the Theory Guide.

21.3.1.3.1. Specifying a User-Defined Function for the Soot Oxidation Rate

You can choose to specify a user-defined function for the soot oxidation rate. The compiled UDF hook is available from the **User Defined Oxidation Rate** drop-down list of the **Soot Model** dialog box. See `DEFINE_SOOT_OXIDATION_RATE` in the *Fluent Customization Manual* for details about user-defined functions.

21.3.1.3.2. Specifying a User-Defined Function for the Soot Precursor Concentration

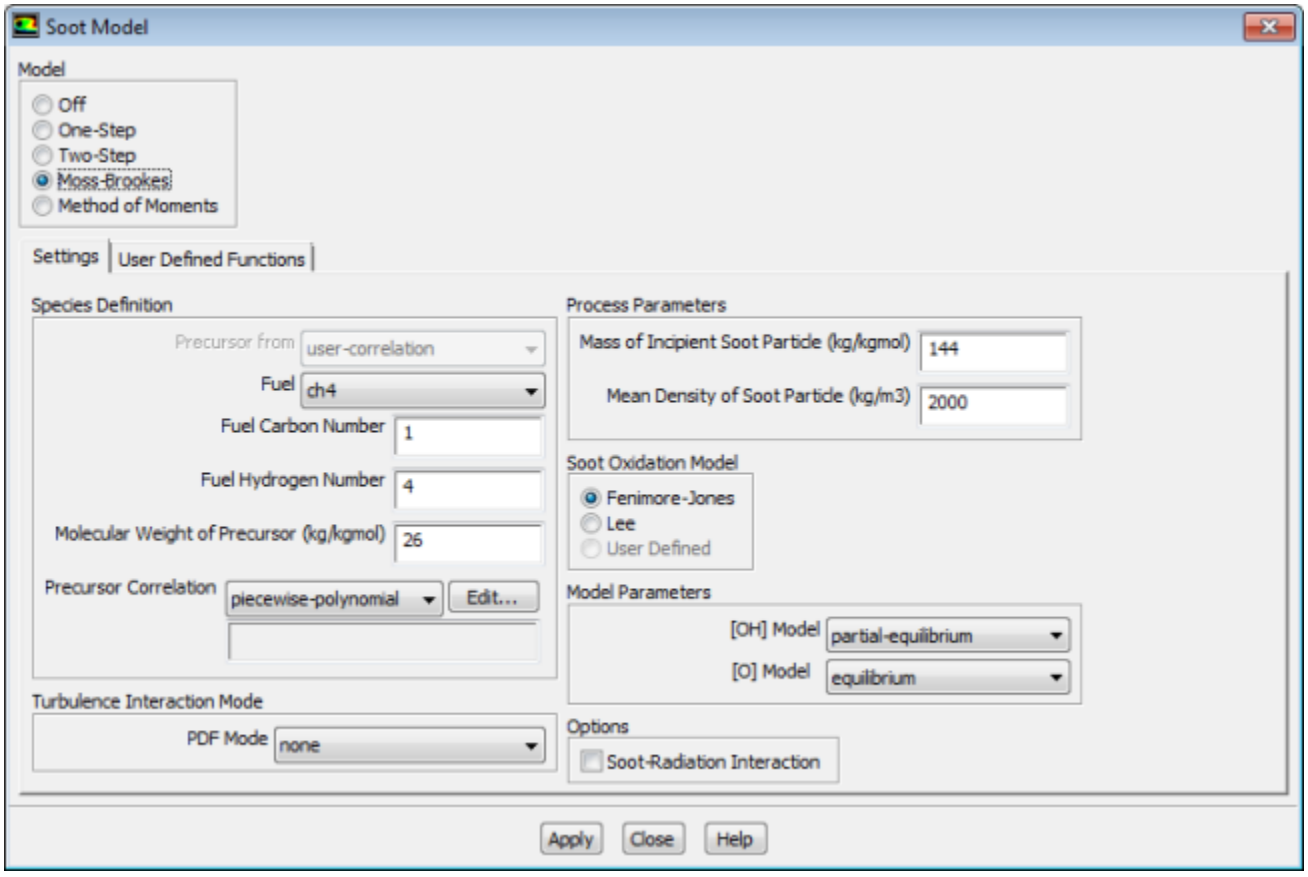
You can choose to specify a user-defined function for the soot oxidation rate. The compiled UDF hook is available from the **User Defined Precursor** drop-down list in the **Species Definition** group box of the **Soot Model** dialog box. See `DEFINE_SOOT_PRECURSOR` in the *Fluent Customization Manual* for details about user-defined functions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

21.3.1.3.3. Species Definition for the Moss-Brookes Model with a User-Defined Precursor Correlation

ANSYS Fluent accepts the following as possible precursor species for the Moss-Brookes model: C_2H_2, C_6H_6, and C_2H_4. If none of these species are present in the species list (as is often the case when using the eddy-dissipation model) or if you would prefer to specify a different precursor correlation, your setup for the Moss-Brookes model will be different than noted previously. Under such circumstances, you should select **user-correlation** from the **Precursor from** drop-down list in the **Species Definition** group box (note that this is only option possible when the appropriate species are not present). The Soot Model Dialog Box (p. 2262) will then be as shown in Figure 21.14: The Soot Model Dialog Box for the Moss-Brookes Model with a User-Defined Precursor Correlation (p. 1194). The parameters you set in the **Species Definition** group box allow ANSYS Fluent to calculate a mixture fraction based on the mass fractions of the oxidant and the carbon/hydrogen contributed by a designated fuel species. The precursor species mass fraction will then be computed as a function (which you will also define) of this mixture fraction.

Figure 21.14: The Soot Model Dialog Box for the Moss-Brookes Model with a User-Defined Precursor Correlation



In the **Species Definition** group box, you will first select a **Fuel** species and enter the related **Fuel Carbon Number** and **Fuel Hydrogen Number** for use in the mixture fraction calculation. Next, enter the **Molecular Weight of Precursor** (the default value is for acetylene). Then make a selection in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Precursor Correlation drop-down list to indicate how the precursor mass fraction will be related to the mixture fraction. A **piecewise-polynomial** profile is defined by default.

Important

Note that the default values for the **piecewise-polynomial** profile are only valid for a methane diffusion flame simulation, in which both the air and fuel initial temperatures are set to 290 K, and acetylene is assumed as the soot precursor.

If you decide not to use the default values for **Precursor Correlation**, you must define the correlation between the precursor mass fraction and the mixture fraction. This correlation should be based on a laminar flamelet profile that you have generated: if possible, you should generate the profile using the **Species Model** dialog box (as described in Setting Up the Steady and Unsteady Diffusion Flamelet Models (p. 1036)), being sure to select **Steady Flamelet** in the **Chemistry** tab; if there is no mechanism, you can generate the profile using the equilibrium chemistry model (see Setting Up the Equilibrium Chemistry Model (p. 1031) for details); you may also use a third-party software package of your choosing. You should then apply a curve-fitting technique to your generated profile, to obtain either a constant value or a piecewise-polynomial function.

In a piecewise-polynomial function, the laminar flamelet profile is divided into a number of mixture fraction ranges. In each range, the precursor species mass fraction Y_{prec} is defined using the following equation:

$$Y_{prec} = \sum_{i=1}^{i=NC} C_i f^{i-1} \tag{21.14}$$

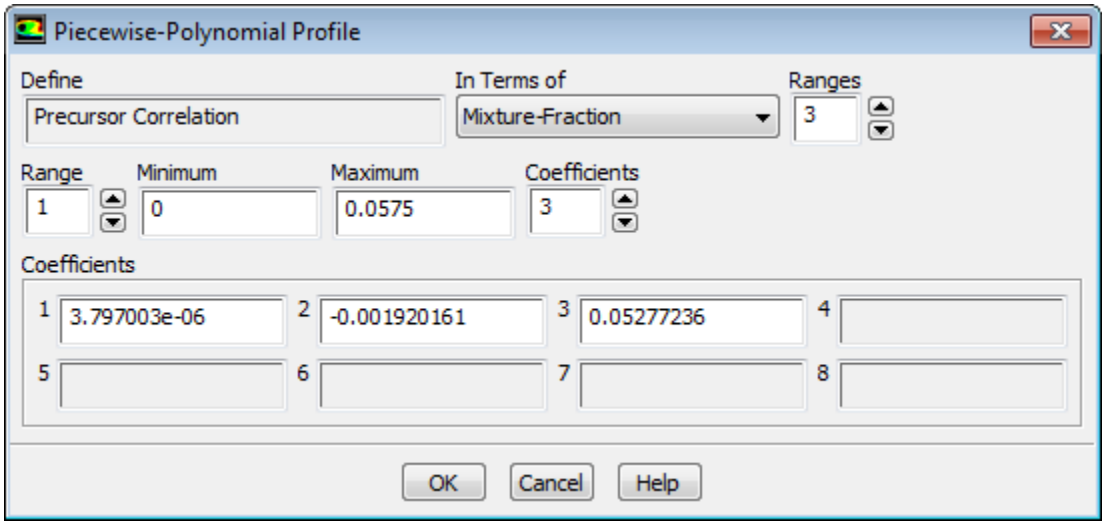
where NC is the number of coefficients C, and f is the mixture fraction. The following piecewise-polynomial function corresponds to the default settings in ANSYS Fluent:

$$Y_{prec} = \begin{cases} \text{for } 0 \le f < 0.0575\text{:} \\ 3.797003\times10^{-6} - 1.920161\times10^{-3} f \\ +5.277237\times10^{-2} f^2 \\ \text{for } 0.0575 \le f < 0.128\text{:} \\ 1.051312 - 71.34743 f + 1964.038 f^2 - 28182.59 f^3 \\ +223543.4 f^4 - 932192 f^5 + 1599627 f^6 \\ \text{for } 0.128 \le f < 1\text{:} \\ 7.988928\times10^{-3} - 8.440912\times10^{-3} f \\ +4.273195\times10^{-4} f^2 \end{cases} \tag{21.15}$$

To define a piecewise-polynomial profile to relate the precursor mass fraction to the mixture fraction, select **piecewise-polynomial** from the **Precursor Correlation** drop-down list and click the **Edit...** button. The Piecewise-Polynomial Profile Dialog Box (p. 2319) (Figure 21.15: The Piecewise-Polynomial Profile Dialog Box (p. 1196)) will open.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.15: The Piecewise-Polynomial Profile Dialog Box



Then perform the following steps in the **Piecewise-Polynomial Profile** dialog box:

1. Enter the number of **Ranges**. For the example shown in Equation 21.15 (p. 1195), three ranges of mixture fraction are defined, which is the maximum allowed.

2. For the first range (**Range** = 1), enter the **Minimum** and **Maximum** mixture fraction values, and the number of **Coefficients**. (Up to eight coefficients are available.) The number of coefficients defines the order of the polynomial. An input of 1 defines a polynomial of order 0, and the mass fraction will be constant and equal to the single coefficient. An input of 2 defines a polynomial of order 1, and the mass fraction will vary linearly with mixture fraction, and so on.

3. Define the values for the coefficients in the **Coefficients** group box. The dialog box in Figure 21.15: The Piecewise-Polynomial Profile Dialog Box (p. 1196) shows the inputs for the first range of Equation 21.15 (p. 1195).

4. Increase the value of **Range** and enter the **Minimum** and **Maximum** mixture fractions, number of **Coefficients**, and the values for the **Coefficients** for the next range. Repeat if there is a third range.

Important

Note when defining the ranges, you must start with the lowest mixture fraction range, and then proceed in order to the highest range. The solver will *not* sort them for you.

To define a constant profile to relate the precursor mass fraction to the mixture fraction, select **constant** from the **Precursor Correlation** drop-down list and enter a value in the accompanying text entry box.

21.3.1.4. Setting Up the Method of Moments Soot Model

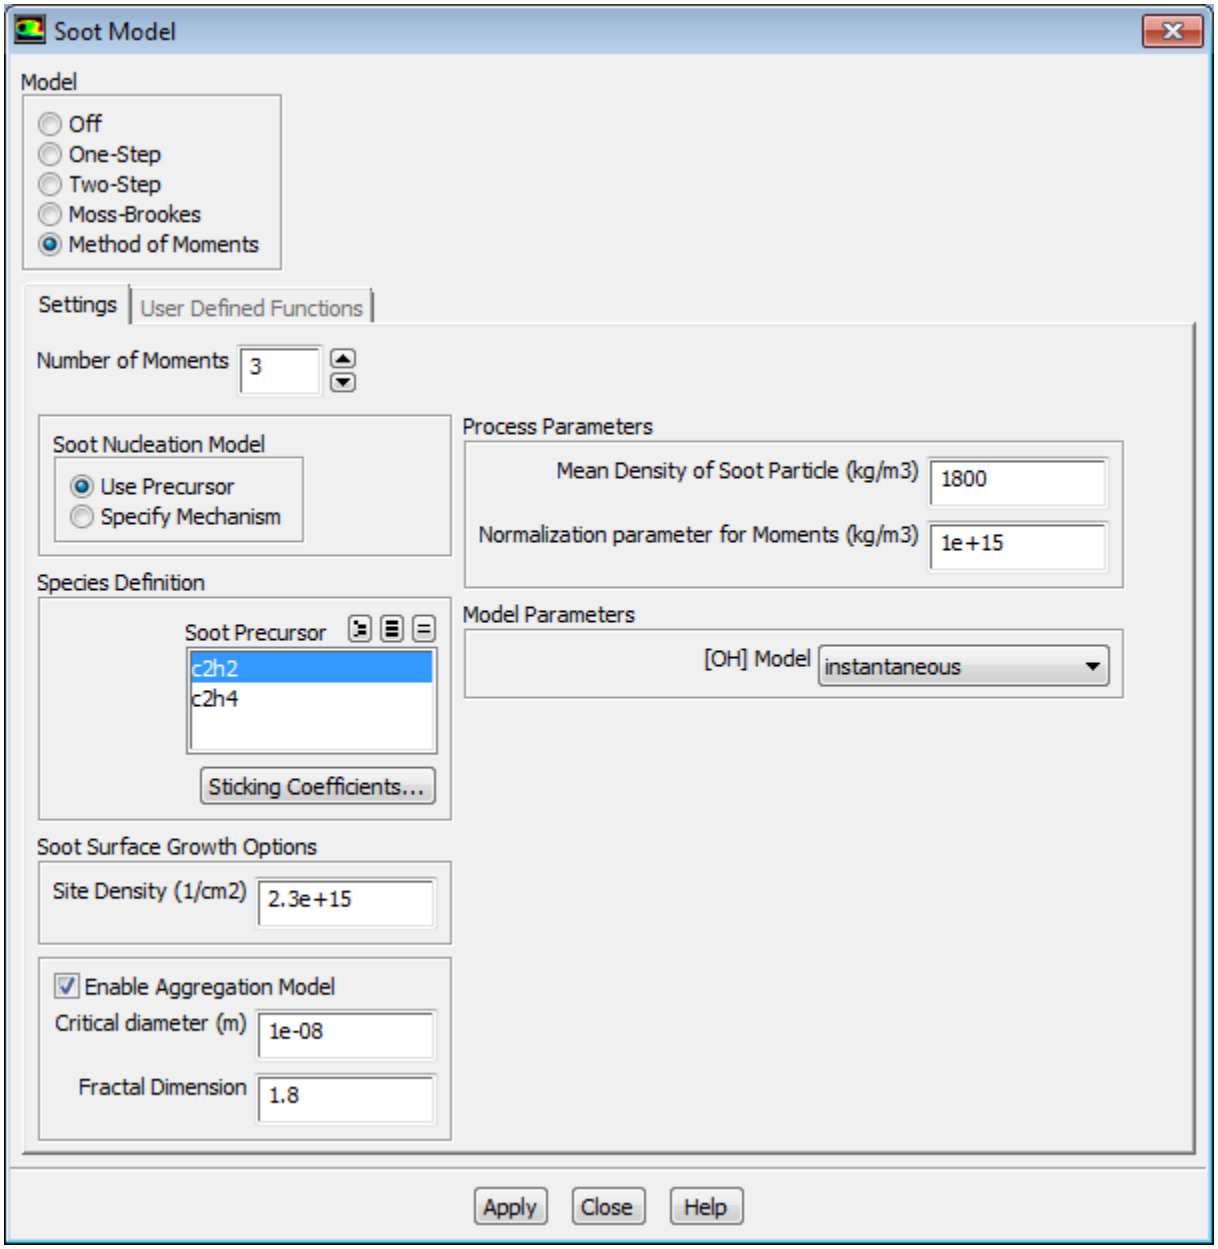
You can enable and set up the Method of Moments model by using the **Soot Model** dialog box (Figure 21.16: The Soot Model Dialog Box for the Method of Moments Model (p. 1197)).

Setup → Models → Species → Soot → Edit...

1. In the **Soot Model** dialog box under **Model**, select **Method of Moments**. The dialog box will expand to show the appropriate inputs.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.16: The Soot Model Dialog Box for the Method of Moments Model



2. Specify **Number Of Moments**.

   ANSYS Fluent will solve an equal number of moment transport equations. The default value of 3 moments works reasonably well for a wide range of applications. However, you can specify up to 6 moments to achieve higher accuracy.

3. From the **Soot Nucleation Model** group box, select one of the following options:

   - **Use Precursor** (default): Enables you to define the precursor species for your soot prediction simulation.
   - **Specify Mechanism**: Enables you to provide the nucleation rate and specify nucleation as a reaction between soot precursors. Using this option, you can achieve more accurate results where the nucleation rate data is available.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. (if **Use Precursor** is selected for the soot nucleation model) Under the **Species Definition** group box, define precursor species.

   a. In the **Soot Precursor** group list (which is populated with all precursors available in your analysis), select one or more precursors.

      The soot precursor species must be a hydrocarbon species. ANSYS Fluent uses kinetic theory to calculate the nucleation rates considering coagulation between precursor species.

   b. Click **Sticking Coefficients...** to specify the sticking coefficient for each precursor in the **Sticking Coefficients** dialog box that will open.

      Figure 21.17: Sticking Coefficients for Soot Precursors

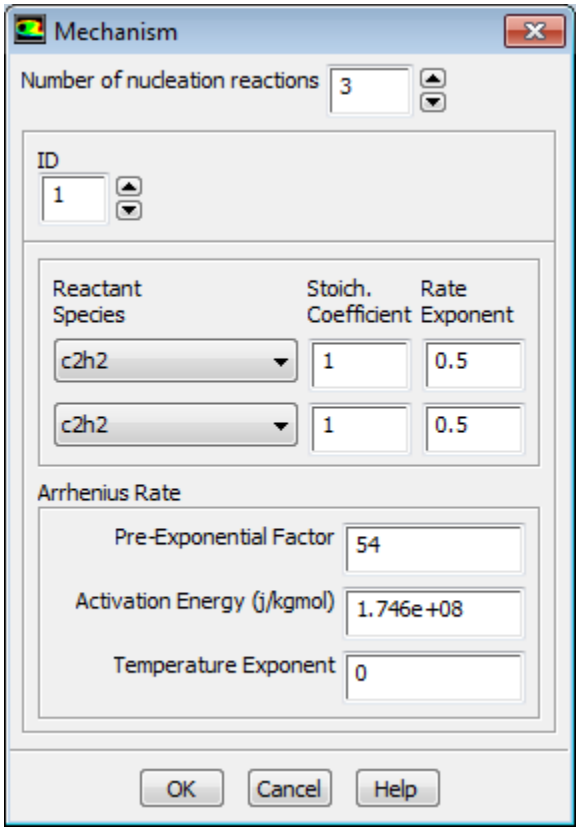
      You must specify the sticking coefficient for each precursor because the nucleation rates calculated based on kinetic theory of collision of two soot precursors are generally very large, causing numerical errors.

> **Important**
>
> The default value for a sticking coefficient is calculated base on precursor molecular weight. In general, you can use smaller values for sticking coefficients for smaller precursors. For guidelines on specifying the sticking coefficients for precursor species, see Nucleation in the *Fluent Theory Guide*.

5. (if **Specify Mechanism** is selected for the soot nucleation model) Click **Set Nucleation Mechanism...** and enter the reaction rates inputs in the **Mechanism** dialog box that will open.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 21.18: Settings for the Nucleation Mechanism



a. Specify **Number of nucleation reactions**.

The nucleation reactions can be single or multi-step.

b. For each reaction, specify the following:

- Reactant species and corresponding stoichiometric coefficient and rate exponent
- The **Arhenius Rate** parameters (**Pre-Exponential Factor**, **Activation Energy**, and **Temperature Exponent**)

Note

The inputs in the **Mechanism** dialog box are required only for reactant species as the main product of specified nucleation reaction is always assumed to be a soot nuclei, and all other products are not considered in calculations of soot nucleation rates.

---

6. If you want to account for soot aggregate formation, select **Enable Aggregation Model**

In addition to the moment transport equations, ANSYS Fluent will solve an equal number of the particle moment transport equations.

Once you have enabled the aggregation model, you can specify the following parameters:

Critical diameter: A value of the soot particle diameter above which the coagulation regime is switched from coalescent coagulation to aggregate coagulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fractal Dimension: A parameter that describes the fractal structure of the aggregate. Values between 1.7 and 2.0 work reasonably good for the aggregate coagulation.

Note

When the **Enable Aggregation Model** option is enabled, the Method of Moments model tends to over-predict the production of soot. This is due, in part, to the linear interpolation of the particle moments. This aspect of the over-prediction can be overcome by employing quadratic interpolation of the particle moments. Another reason for the over-prediction of soot is due to how ANSYS Fluent currently ignores the depletion of acetylene during the soot calculations. Acetylene is consumed during the surface growth of soot, and since ANSYS Fluent generates the flamelets before the solution, the flamelets have no knowledge of the soot process, thereby producing a higher surface growth of soot, and eventually higher soot yields.

For information about the aggregation model, see Soot Aggregation in the *Fluent Theory Guide*.

7. Under **Soot Surface Growth Options**, specify **Soot Density**.

   The growth of soot due to surface reactions and depletion due to oxidation reactions are modeled using HACA mechanism (see Surface Growth and Oxidation in the separate Theory Guide). For reaction rates and reaction steps, ANSYS Fluent uses default values and requires no user inputs except for the soot site density.

   Note

   You can specify and/or edit the reaction rates of surface reactions using the `define/models/soot-parameters` text command.

   Important

   The soot site density is always provided in units of number of sites per cm^2 irrespective of the unit system selected in ANSYS Fluent.

   ---

8. Under **Process Parameters**, specify **Mean Density of Soot Particle** and **Normalization Parameter for Moments**.

   The normalization parameter is used to minimize numerical errors when solving the normalized soot moment transport equations. The default value for this parameter is sufficient, and you may not need to change it.

9. Specify the **Modeling Parameters**:

   - **[OH] Model**: Specifies the method by which the [OH] radical concentration is calculated. For **OH Model**, the following options are available:

     – `instantaneous` (recommended where possible)

       This option is only available when OH is present in the species list and participate in the combustion simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - `partial-equilibrium`

    This option necessitates the availability of [O] atom concentration within the field.

- **[O] Model** (available only if `instantaneous` is not selected for **OH Model**): Specifies the method by which the [O] radical concentration is calculated. The following options are available:

  - `equilibrium`
  - `partial-equilibrium`
  - `instantaneous`

21.3.1.5. Defining Boundary Conditions for the Soot Model

At flow inlet boundaries, you must specify the **Soot Mass Fraction** and (when not using the one-step model) the **Nuclei** mass concentration. These correspond to Y_{soot} in Equation 14.126 and Equation 14.140 and b^*_{nuc} in Equation 14.132 and Equation 14.140 in the Theory Guide, respectively.

Setup → **Boundary Conditions**

You can retain the default inlet values of zero for both quantities or you can enter nonzero numbers as appropriate for your combustion system.

21.3.1.6. Reporting Soot Quantities

ANSYS Fluent provides additional reporting options when your model includes soot formation. You can generate graphical plots or alphanumeric reports of the following items:

- **Mass fraction of Soot**
- **Mole fraction of Soot**
- **Soot Density**
- **Soot Volume fraction**
- **Rate of Soot**
- **Normalized Concentration of Nuclei** (unavailable for one-step model)
- **Rate of Nuclei** (unavailable for one-step model)
- **Rate of Soot Mass Nucleation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Surface Growth** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Oxidation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Nucleation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Rate of Coagulation** (Moss-Brookes and Moss-Brookes-Hall models only)
- **Soot Surface Area** (Method of Moments model only)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Soot Mean Diameter** (Method of Moments model only)
- **Normalized soot moments** (Method of Moments model only)
- **Normalized Soot Aggregation Moments** (Method of Moments model with Aggregation only)
- **Average Number of Particles in Soot Aggregate** (Method of Moments model with Aggregation only)
- **Primary Particle Diameter** (Method of Moments model with Aggregation only)

These parameters are contained in the **Soot...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

21.4. Using the Decoupled Detailed Chemistry Model

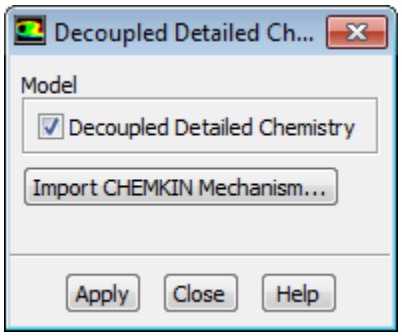
The decoupled detailed chemistry pollutant model is used to postprocess slowly-forming, trace pollutant species on a steady-state flow field using detailed chemical kinetic mechanisms. For theoretical information, refer to Decoupled Detailed Chemistry Model. The recommended procedure is as follows:

1. Calculate your steady combustion problem using the Species Transport, Non-Premixed, Partially-Premixed, or PDF Transport models in ANSYS Fluent. It is recommended that you save your case and data file, as it may be difficult to revert to the original settings after you set up the decoupled detailed chemistry pollutant model.

2. Enable the **Decoupled Detailed Chemistry** option in the **Decoupled Detailed Chemistry** dialog box. To access this dialog box, make sure that either the non-premixed or partially premixed model is selected, or that reactions are enabled if the species transport or PDF transport models are used.

   Setup → Models → Species → Decoupled Detailed Chemistry → Edit...

   Figure 21.19: The Decoupled Detailed Chemistry Dialog Box

3. Click **Import CHEMKIN Mechanism...** to import your detailed chemistry mechanism in CHEMKIN format. The **CHEMKIN Mechanism Import** dialog box (described in Importing a Volumetric Kinetic Mechanism in CHEMKIN Format (p. 967)) will open, where you will browse to the file. After the CHEMKIN mechanism is imported, the **Decoupled Detailed Chemistry** dialog box will expand to include the species.

   The species in the initial detailed chemical kinetic mechanism used to obtain the steady-state solution appear in the **Original Species** list. The species in the detailed chemistry mechanism you have imported appear in the **Pollutant Species** list. Note that if the species is present in both mechanisms, it will be listed only under **Original Species** and will not be available as a pollutant species.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select the **Pollutant Species** and click **Apply**. The pollutant species are typically slowly forming (far from chemical equilibrium), and occur at miniscule mass fractions. ANSYS Fluent will create a mixture material called **pollutant-mixture** and enable the **Species Transport** model with the **Stiff Chemistry Solver**. All species in the imported mechanism that were not in the original combustion model and are not pollutant species will be calculated by chemical equilibrium at the cell temperature. The solution of all transport equations, except the selected pollutant species, are disabled.

   Note

   Species that are not identified as pollutants and do not participate in the reactions amongst the pollutant species are eliminated. Similarly, reactions in the imported CHEMKIN mechanism, which do not include any pollutant species are also eliminated.

5. Click **Integration Parameters...** to open the **Integration Parameters** dialog box. Set the **ISAT Parameters**, such as the **ISAT Error Tolerance** and **Max. Storage**. An **ISAT Error Tolerance** of 1e-5 is recommended, and **Max. Storage** should be set to a large fraction of the free RAM memory available. To learn more about setting integration parameters, refer to Using ISAT (p. 1128).

6. Define the boundary conditions for all pollutants at flow inlets (these are usually zero).

   Setup → Boundary Conditions

7. Iterate until convergence.

   Solution → Run Calculation

8. Review the mass fractions of pollutants by generating graphical plots or alphanumeric reports in the usual way.

9. Save a new set of case and data files, if desired.

   File → Write → Case & Data...

Chapter 22: Predicting Aerodynamically Generated Noise

This chapter provides an overview of ANSYS Fluent's approaches to computing aerodynamically generated sound, the model setup, and the procedure for computing sound. For more information about the underlying theory behind aerodynamically generated sound, see Aerodynamically Generated Noise in the Theory Guide.

22.1. Overview
22.2. Using the Ffowcs-Williams and Hawkings Acoustics Model
22.3. Using the Broadband Noise Source Models

22.1. Overview

Considering the breadth of the discipline and the challenges encountered in aerodynamically generated noise, it is not surprising that a number of computational approaches have been proposed over the years whose sophistication, applicability, and cost widely vary.

ANSYS Fluent offers three approaches to computing aerodynamically generated noise; a direct method, an integral method based on acoustic analogy and a method that utilizes broadband noise source models.

For additional information, see the following sections:

22.1.1. Direct Method
22.1.2. Integral Method Based on Acoustic Analogy
22.1.3. Broadband Noise Source Models

22.1.1. Direct Method

In this method, both generation and propagation of sound waves are directly computed by solving the appropriate fluid dynamics equations. Prediction of sound waves always requires time-accurate solutions to the governing equations. Furthermore, in most practical applications of the direct method, one has to employ governing equations that are capable of modeling viscous and turbulence effects, such as unsteady Navier-Stokes equations (that is, DNS), RANS equations, and filtered equations used in LES and hybrid RANS-LES models.

The direct method is therefore computationally difficult and expensive inasmuch as it requires highly accurate numerics, very fine computational meshes all the way to receivers, and acoustically nonreflecting boundary conditions. The computational cost becomes prohibitive when sound is to be predicted in the far field (for example, hundreds of chord-lengths in the case of an airfoil). The direct method becomes feasible when receivers are in the near field (for example, cabin noise). In many such situations involving near-field sound, sounds (or pseudo-sounds for that matter) are predominantly due to local hydrodynamic pressure, which can be predicted with a reasonable cost and accuracy.

Since sound propagation is directly resolved in this method, you would normally solve the compressible form of the governing equations (for example, compressible RANS equations, compressible form of filtered equations for LES). Only in situations where the flow is low subsonic and the receivers in the near field sense primarily local hydrodynamic pressure fluctuations (that is, pseudo sound) can incom-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

pressible flow formulations be used. But this incompressible treatment will also not allow you to simulate resonance and feedback phenomena.

22.1.2. Integral Method Based on Acoustic Analogy

For predictions of mid- to far-field noise, the methods based on Lighthill's acoustic analogy [58] (p. 2890) offer viable alternatives to the direct method. In this approach, the near-field flow obtained from appropriate governing equations such as unsteady RANS equations, DES, SAS, SDES, SBES, or LES are used to predict the sound with the aid of analytically derived integral solutions to wave equations. The acoustic analogy essentially decouples the propagation of sound from its generation, allowing one to separate the flow solution process from the acoustics analysis.

ANSYS Fluent offers a method based on the Ffowcs-Williams and Hawkings (FW-H) formulation [30] (p. 2888). The FW-H formulation adopts the most general form of Lighthill's acoustic analogy, and is capable of predicting sound generated by equivalent acoustic sources such as monopoles, dipoles, and quadrupoles. ANSYS Fluent adopts a time-domain integral formulation wherein time histories of sound pressure, or acoustic signals, at prescribed receiver locations are directly computed by evaluating a few surface integrals.

Time-accurate solutions of the flow-field variables, such as pressure, velocity components, and density on source (emission) surfaces, are required to evaluate the surface integrals. Time-accurate solutions can be obtained from unsteady Reynolds-averaged Navier-Stokes (URANS) equations, large eddy simulation (LES), or hybrid RANS-LES models as appropriate for the flow at hand and the features that you want to capture (for example, vortex shedding). The source surfaces can be placed not only on impermeable walls, but also on interior (permeable) surfaces, which enables you to account for the contributions from the quadrupoles enclosed by the source surfaces. Both broadband and tonal noise can be predicted depending on the nature of the flow (noise source) being considered, turbulence model employed, and the time scale of the flow resolved in the flow calculation.

The FW-H acoustics model in ANSYS Fluent allows you to select multiple source surfaces and receivers. It also permits you either to save the source data for a future use, or to carry out an "on the fly" acoustic calculation simultaneously as the transient flow calculation proceeds, or both. Sound pressure signals therefore obtained can be processed using the fast Fourier transform (FFT) and associated postprocessing capabilities to compute and plot such acoustic quantities as the overall sound pressure level (SPL) and power spectra.

One important limitation of ANSYS Fluent's FW-H model is that it is applicable only to predicting the propagation of sound toward *free space*. Therefore, while the model can be legitimately used to predict far-field noise due to external aerodynamic flows, such as the flows around ground vehicles and aircraft, it cannot be used for predicting the noise propagation inside ducts or wall-enclosed space.

22.1.3. Broadband Noise Source Models

In many practical applications involving turbulent flows, noise does not have any distinct tones, and the sound energy is continuously distributed over a broad range of frequencies. In those situations involving *broadband noise*, statistical turbulence quantities readily computable from RANS equations can be utilized, in conjunction with semi-empirical correlations and Lighthill's acoustic analogy, to shed some light on the source of broadband noise.

ANSYS Fluent offers several such *source models* that enable you to quantify the local contribution (per unit surface area or volume) to the total acoustic power generated by the flow. They include the following:

- Proudman's formula

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- jet noise source model
- boundary layer noise source model
- source terms in the linearized Euler equations
- source terms in Lilley's equation

Considering that one would ultimately want to come up with some measures to mitigate the noise generated by the flow in question, the source models can be employed to extract useful diagnostics on the noise source to determine which portion of the flow is primarily responsible for the noise generation. Note, however, that these source models do not predict the sound at receivers.

Unlike the direct method and the FW-H integral method, the broadband noise source models do not require transient solutions to any governing fluid dynamics equations. All the source models need is what typical RANS models would provide, such as the mean velocity field, turbulent kinetic energy (k) and the dissipation rate (ε). Therefore, the use of broadband noise source models requires the least computational resources.

22.2. Using the Ffowcs-Williams and Hawkings Acoustics Model

The procedure for computing sound using the FW-H acoustics model in ANSYS Fluent consists largely of two steps. In the first step, a time-accurate flow solution is generated from which time histories of the relevant variables (for example, pressure, velocity, and density) on the selected source surfaces are obtained. In the second step, sound pressure signals at the user-specified receiver locations are computed using the source data collected during the first step.

Important

Note that you can also use the FW-H model for a steady-state simulation in the case where your model has a single moving reference frame. Here, the thickness and loading noise due to the motion of the noise sources is computed using the FW-H integrals (see Equation 15.5 and Equation 15.6 in the Theory Guide), except that the term involving the time derivative of surface pressure (contribution to $\dot{L}_r$ in Equation 15.6 in the Theory Guide) is set to zero.

In computing sound pressure using the FW-H integral solution, ANSYS Fluent uses a so-called "forward-time projection" to account for the time delay between the emission time (the time at which the sound is emitted from the source) and the reception time (the time at which the sound arrives at the receiver location). The forward-time projection approach enables you to compute sound at the same time "on the fly" as the transient flow solution progresses, without having to save the source data.

In this section, the procedure for setting up and using the FW-H acoustics model is outlined first, followed by detailed descriptions of each of the steps involved. Remember that only the steps that are pertinent to acoustics modeling are discussed here. For information about the inputs related to other models that you are using in conjunction with the FW-H acoustics model, see the appropriate sections for those models.

The general procedure for carrying out an FW-H acoustics calculation in ANSYS Fluent is as follows:

1. Calculate a converged flow solution. For a transient case, run the transient solution until you obtain a "statistically steady-state" solution as described below.
2. Enable the FW-H acoustics model and set the associated model parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Acoustics Edit...

3. Specify the source surface(s) and choose the options associated with acquisition and saving of the source data. For a steady-state case, specify the rotating surface zone(s) as the source surface(s).

4. Specify the receiver location(s).

5. Continue the transient solution for a sufficiently long period of time and save the source data (transient cases only).

   Solution → Run Calculation

6. Compute and save the sound pressure signals.

   Solution → Run Calculation → Acoustic Signals...

7. Postprocess the sound pressure signals.

   Results → Plots → FFT Edit...

Important

Before you start the acoustics calculation for a transient case, an ANSYS Fluent transient solution should have been run to a point where the transient flow field has become "statistically steady". In practice, this means that the unsteady flow field under consideration, including all the major flow variables, has become fully developed in such a way that its statistics do not change with time. Monitoring the major flow variables at selected points in the domain is helpful for determining if this condition has been met.

As discussed earlier, URANS, LES, and hybrid RANS-LES models are all legitimate candidates for transient flow calculations. For stationary source surfaces, the frequency of the aerodynamically generated sound heard at the receivers is largely determined by the time scale or frequency of the underlying flow. Therefore, one way to determine the time-step size for the transient computation is to make it small enough to resolve the smallest characteristic time scale of the flow at hand that can be reproduced by the mesh and turbulence adopted in your model.

Once you have obtained a statistically stationary flow-field solution, you are ready to acquire the source data.

For additional information, see the following sections:

22.2.1. Enabling the FW-H Acoustics Model
22.2.2. Specifying Source Surfaces
22.2.3. Specifying Acoustic Receivers
22.2.4. Specifying the Time Step
22.2.5. Postprocessing the FW-H Acoustics Model Data
22.2.6. FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra

22.2.1. Enabling the FW-H Acoustics Model

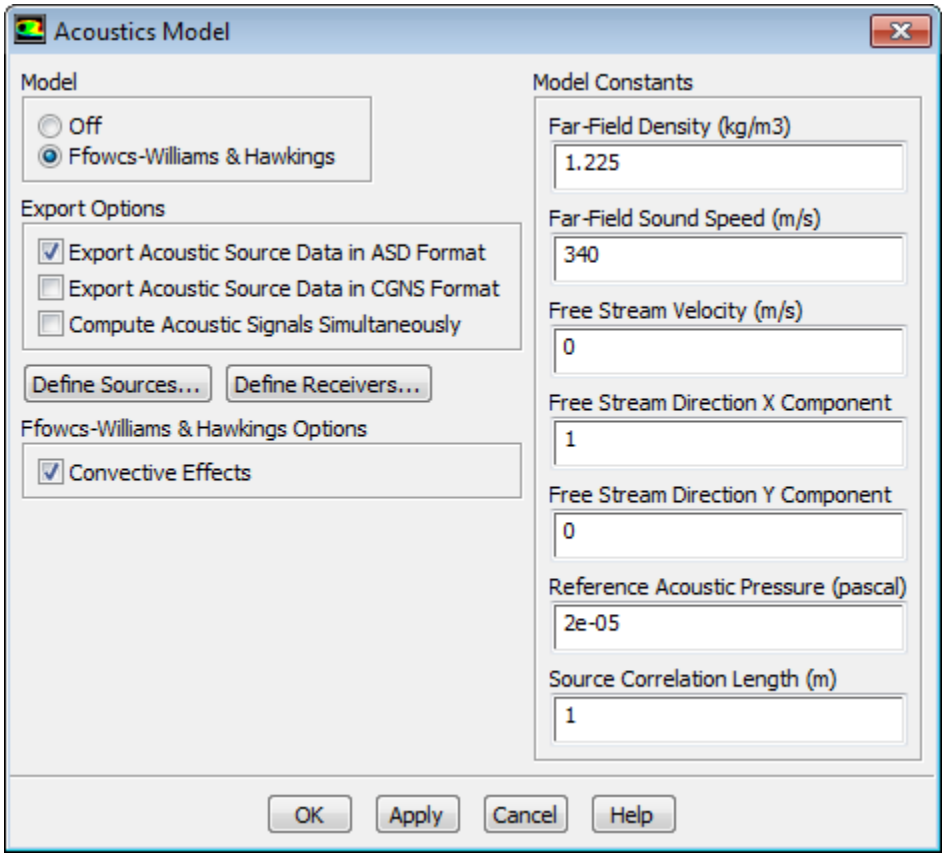
To enable the FW-H acoustics model, select **Ffowcs-Williams & Hawkings** in the **Acoustics Model** dialog box (Figure 22.1: The Acoustics Model Dialog Box (p. 1209)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Acoustics Edit...

When you select **Ffowcs-Williams & Hawkings**, the dialog box will expand to show the relevant fields for user inputs.

Figure 22.1: The Acoustics Model Dialog Box



22.2.1.1. Setting Model Constants

Under **Model Constants** in the **Acoustics Model** dialog box, specify the relevant acoustic parameters and constants used by the model.

Far-Field Density

(for example, ρ_0 in Equation 15.1 in the Theory Guide) is the far-field fluid density.

Far-Field Sound Speed

(for example, a_0 in Equation 15.1) is the sound speed in the far field (= $\sqrt{\gamma R T_0}$).

Free Stream Velocity and Free Stream Direction
are required when the convective effects are taken into account. They become available in the interface when **Convective Effects** is enabled.

> **Important**
>
> The use of **Convective Effects** with the proper **Free Stream Velocity** and **Free Stream Direction** is strongly recommended for all cases dealing with external flows around bodies.

Reference Acoustic Pressure
(for example, p_{ref} in Equation 31.41 (p. 1880)) is used to calculate the sound pressure level in dB (see Using the FFT Utility (p. 1875)). The default reference acoustic pressure is 2×10^{-5} Pa.

Number of Time Steps Per Revolution
is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of equivalent time steps that it will take for the rotating zone to complete one revolution.

Number of Revolutions
is available only for steady-state cases that have a single moving reference frame. Here you will specify the number of revolutions that will be simulated in the model.

Source Correlation Length
is required when sound is to be computed using a 2D flow result. The FW-H integrals will be evaluated over this length in the depth-wise direction using the identical source data (see Figure 22.2: The Acoustics Model Dialog Box for a 2D Steady-State Case with a Single Moving Reference Frame (p. 1212)).

The default values are appropriate for sound propagating in air at atmospheric pressure and temperature.

22.2.1.2. Computing Sound "on the Fly"

The FW-H acoustics model in ANSYS Fluent allows you to perform simultaneous calculation of the sound pressure signals at the prescribed receivers without having to write the source data to files, which can save a significant amount of disk space on your machine. To enable this "on-the-fly" calculation of sound, enable the **Compute Acoustic Signals Simultaneously** option in the **Acoustics Model** dialog box.

> **Important**
>
> Because the noise computation takes a negligible percentage of memory and computational time compared to a transient flow calculation, this option can be used by itself or along with the process of source data file export and sound calculation. For the latter, computing signals "on the fly" allows you to see when the signals have become statistically steady so you can know when to stop the simulation.

When the **Compute Acoustic Signals Simultaneously** option is enabled, the ANSYS Fluent console window will print a message at the end of each time step indicating that the sound pressure signals have been computed (for example, `Computing sound signals at x receiver locations...`, where `x` is the number of receivers you specified). Enabling this option instructs ANSYS

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Fluent to compute sound pressure signals at the end of each time step, which will slightly increase the computation time.

Important

Note that this option is available only when the FW-H acoustics model has been enabled. See below for details about exporting source data without enabling the FW-H model.

22.2.1.3. Writing Source Data Files

Although the "on-the-fly" capability is a convenient feature, you will want to save the source data as well, because the acquisition of source data during a transient flow-field calculation is the most time-consuming part of acoustics computations, and you most likely will not want to discard it. By saving the source data, you can always reuse it to compute the sound pressure signals at new or additional receiver locations.

To save the source data to files, enable either the **Export Acoustic Source Data in ASD Format** or the **Export Acoustic Source Data in CGNS Format** option, or both. After you have made your selection, the relevant source data at all face elements of the selected source surfaces will be written into the files you specify. The source data vary depending on the solver option you have chosen and whether the source surface is a wall or not. Table 22.1: Source Data Saved in Source Data Files (p. 1212) shows the flow variables saved as the source data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.2: The Acoustics Model Dialog Box for a 2D Steady-State Case with a Single Moving Reference Frame

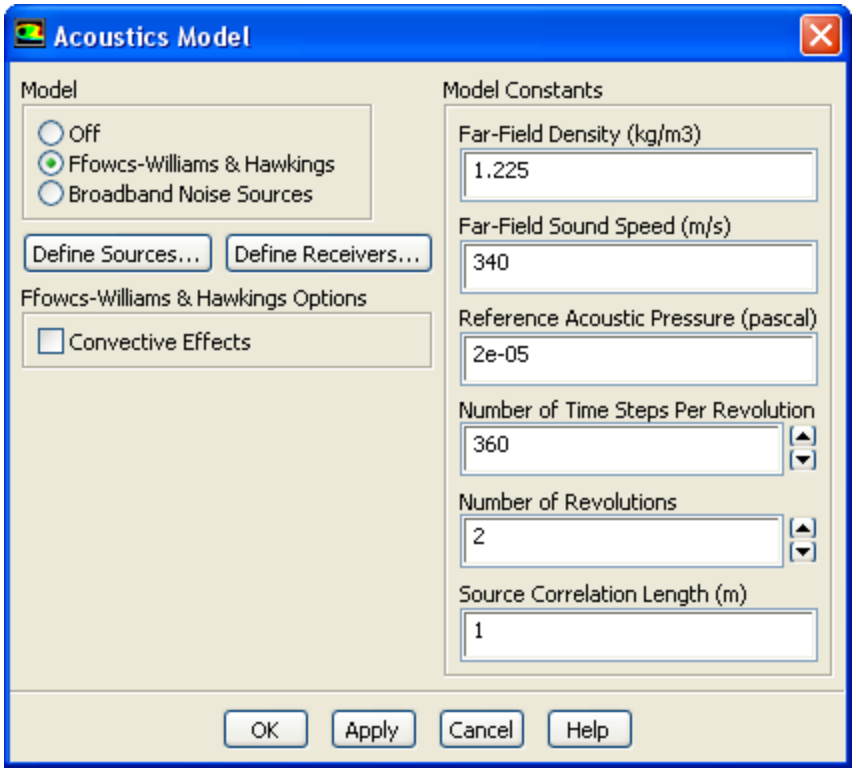


Table 22.1: Source Data Saved in Source Data Files

Solver Option	Source Surface	Source Data
incompressible	walls	p
incompressible	permeable surfaces	p,u,v,w
compressible	walls	p
compressible	permeable surfaces	ρ,p,u,v,w

See Specifying Source Surfaces (p. 1214) for details on how to specify parameters for exporting source data.

22.2.1.3.1. Exporting Source Data Without Enabling the FW-H Model: Using the ANSYS Fluent ASD Format

You can export sound source data for use with SYSNOISE without having to enable the Ffowcs-Williams and Hawkings (FW-H) model. You still must specify source surfaces (see Specifying Source Surfaces (p. 1214)), as `.index` and `.asd` files are required by SYSNOISE. In addition, you can choose fluid zones as emission sources if you want to export quadrupole sources. To enable the selection of fluid zones as sources, use the

`define` → `models` → `acoustics` → `export-volumetric-sources?`

text command and change the selection to `yes`.

SYSNOISE also requires centroid data for source zones that are being exported.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For fan noise calculations, once you have specified the source zones in the **Acoustic Sources** dialog box and you have selected **Export Acoustic Source Data in ASD Format** from the **Acoustics Model** dialog box, you can export geometry in cylindrical coordinates by using the

`define` → `models` → `acoustics` → `cylindrical-export?`

text command and changing the selection to `yes`. By default, ANSYS Fluent exports source zones for SYSNOISE in Cartesian coordinates.

You can then export the centroid data to a data file using the following text command:

`define` → `models` → `acoustics` → `write-centroid-info`

Since you will not be using the FW-H model to compute signals, you will not need to specify any acoustic model parameters or receiver locations. Also, you will not be able to enable the **Compute Acoustic Signals Simultaneously** option in the **Acoustics Model** dialog box, and **Acoustic Signals...** will not be available in the **Run Calculation** task page and in the menu for the **Run Calculation** tree item.

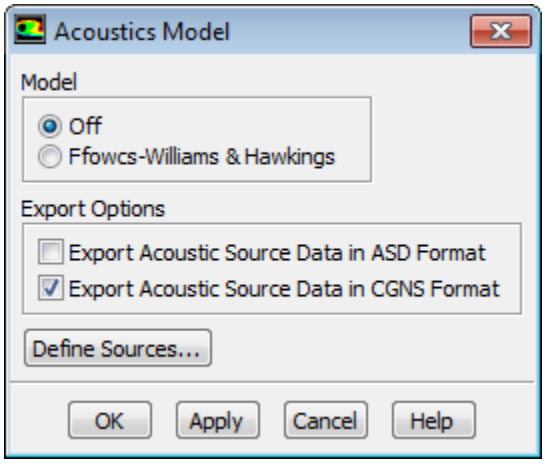
22.2.1.3.2. Exporting Source Data Without Enabling the FW-H Model: Using the CGNS Format

The sound source data for non-permeable surfaces can be exported in the CGNS file format (for Virtual Lab) without having to enable the Ffowcs-Williams and Hawkings (FW-H) model. Enable the **Export Acoustic Source Data in CGNS Format** option in the **Acoustics Model** dialog box (Figure 22.3: The Acoustics Model Dialog Box for Exporting in CGNS Format (p. 1213)). Specify the source surfaces in the **Acoustics Sources** dialog box (see Specifying Source Surfaces (p. 1214)) where, by default, the **Number of Time Steps per File** is set to `1`.

Note

ANSYS Fluent does not support exporting acoustic source data in CGNS format for polyhedral meshes.

Figure 22.3: The Acoustics Model Dialog Box for Exporting in CGNS Format



Virtual Lab requires a mesh data file (named `<prefix>_mesh.cgns`) and a solution data file (named `<prefix>_<timestep>.cgns`). The string `<prefix>` is a generic name, which you will specify in the **Source Data Root File Name** in the **Acoustics Sources** dialog box. There is one single solution

data file (`.cgns`) per time level exported, which contains the static pressure at the wall-face centroid location. The `.cgns` files will be stored in a directory, which you specify (named `<directory_name>/<prefix>`) in the **Source Data Root File Name**.

In addition, you can export quadrupole sources data by choosing fluid zones as emission sources. To enable the selection of fluid zones as sources, use the text command:

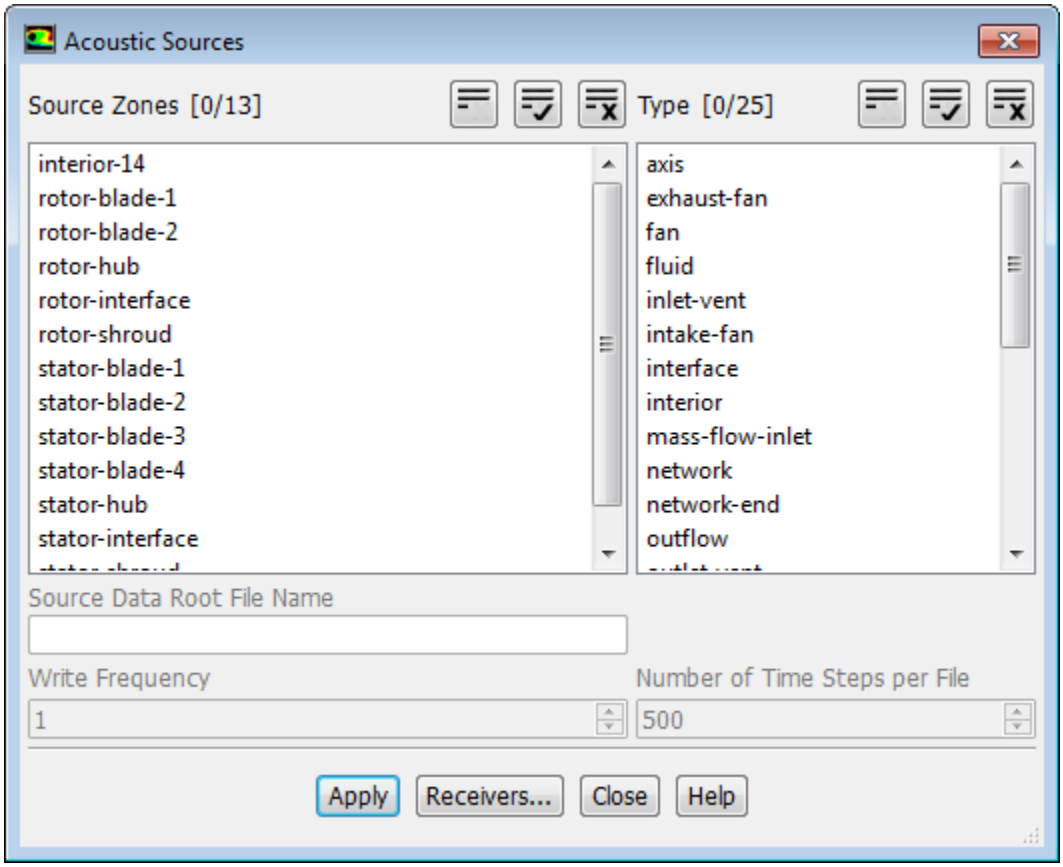
`define` → `models` → `acoustics` → `export-volumetric-sources-cgns?`

When asked if you would like to `Export volumetric sources?` enter `yes`. Note that Virtual Lab requires volumetric mesh data file (`<prefix>_Q_mesh.cgns`) and quadrupole solution data files (`<prefix>_Q_<timestep>.cgns`). The `.cgns` file will be stored in a similar way to that of dipole data export, in the directory specified by you in the **Source Data Root File Name** text entry box.

22.2.2. Specifying Source Surfaces

In the **Acoustics Model** dialog box, click the **Define Sources...** button to open the **Acoustic Sources** dialog box (Figure 22.4: The Acoustics Model Dialog Box (p. 1214)). Here you will specify the source surface(s) to be used in the acoustics calculation and the inputs associated with saving source data to files.

Figure 22.4: The Acoustics Model Dialog Box



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Under **Source Zones**, you can select multiple emission (source) surfaces and the surface **Type** that you can select is *not* limited to a **wall**. You can also choose **interior** surfaces and sliding interfaces (both stationary and rotating) as source surfaces.

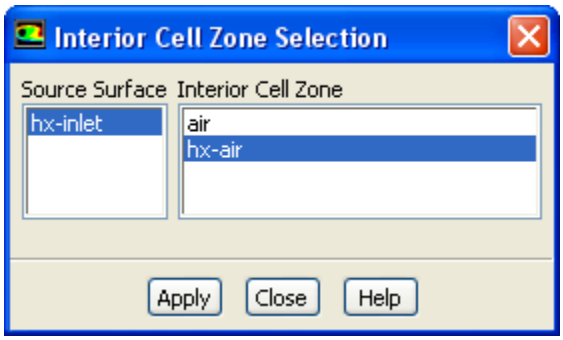
Important

The ability to choose multiple source surfaces is useful for investigating the contributions from individual source surfaces. The results based on the use of multiple source surfaces are valid as long as there are negligible acoustic interactions among the surfaces. Therefore, some caution should be taken when selecting multiple source surfaces.

In cases where multiple source surfaces are selected, no source surface may enclose any of the other source surfaces. Otherwise, the sound pressure calculated based on the source surfaces will not be accurate, as the contribution from the enclosed (inner) source surfaces is over predicted, since the FW-H model is unable to account for the shading of the sound from the inner source surfaces by the enclosure surface.

If you specify any interior surfaces as source surfaces, the interior surface must be generated in advance (for example, in GAMBIT) in such a way that the two cell zones adjacent to the surface have different cell zone IDs. Furthermore, you must correctly specify which of the two zones is occupied by the quadrupole sources (interior cell zone). This will allow ANSYS Fluent to determine the direction in which the sound will propagate. When you first attempt to select a legitimate interior surface (that is, an interior surface having two different cell zones on both sides) as a source surface, the Interior Cell Zone Selection Dialog Box (p. 2294) (Figure 22.5: The Interior Cell Zone Selection Dialog Box (p. 1215)) will appear. You must then select the interior cell zones from the two zones listed under the **Interior Cell Zone**. Figure 22.6: An Interior Source Surface (p. 1216) shows an example of an interior source surface.

Figure 22.5: The Interior Cell Zone Selection Dialog Box



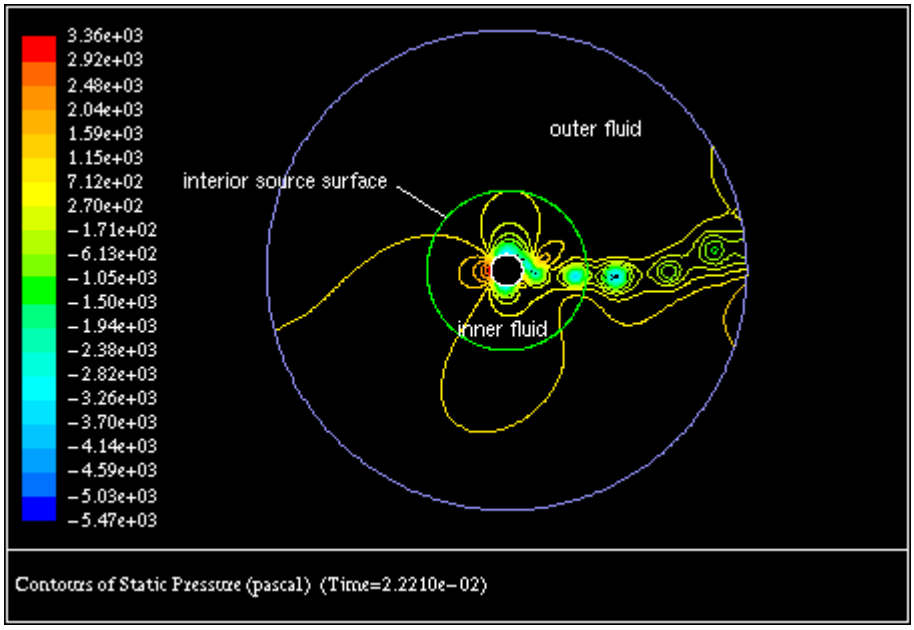
Like general interior surfaces, if the source surfaces selected are sliding interfaces, a dialog box similar to Figure 22.5: The Interior Cell Zone Selection Dialog Box (p. 1215) will appear that will show the two adjacent cell zones and you will be asked to specify the zone that has the sound sources.

Important

When a permeable surface (either interior or sliding interface) is chosen as the source surface, other wall surfaces inside the volume enclosed by the permeable surface that generate sound should not be chosen for the acoustics calculation. For example, when running an "on-the-fly" calculation, if both these surfaces are selected, the sound pressure will be counted twice.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.6: An Interior Source Surface



22.2.2.1. Saving Source Data

To save the source data, you have to specify the **Source Data Root File Name**, **Write Frequency** (in number of time steps), and **Number of Time Steps per File** in the **Acoustic Sources** dialog box.

The **Source Data Root File Name** is used to give the names of the source data files (for example, `acoustic_examplexxxx.asd`, where `xxxx` is the global time-step index of the transient solution) and an index file (for example, `acoustic_example.index`) that will store the information associated with the source data. The **Write Frequency** allows you to control how often the source data will be written. This will enable you to save disk space if the time-step size used in the transient flow simulation is smaller than necessary to resolve the sound frequency you are attempting to predict. In most situations, however, you will want to save the source data at every time step and use the default value of `1`.

Since acoustics calculations usually generate thousands of time steps of source data, you may want to split the data into several files. Specifying the **Number of Time Steps per File** allows you to write the source data into separate files for different simulation intervals, the duration of which (in terms of the number of transient flow time steps) is specified by you. For example, if you specify 100 for this parameter, each file will contain source data for an interval length of 100 time steps regardless of the write frequency.

You will find this feature useful if you want to use a selected number of source data files to compute the sound pressure rather than using all the data. For example, you may want to exclude an initial portion of the source data from your acoustics calculation because you may realize later that the flow field has not fully attained a statistically steady state.

After you click **Apply**, ANSYS Fluent will create the index file (for example, `acoustics_example.index`), which contains information about the source data.

Important

If you choose to save source data, keep in mind that the source data can use up a considerable amount of disk space, especially if the mesh being used has a large number of face elements

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

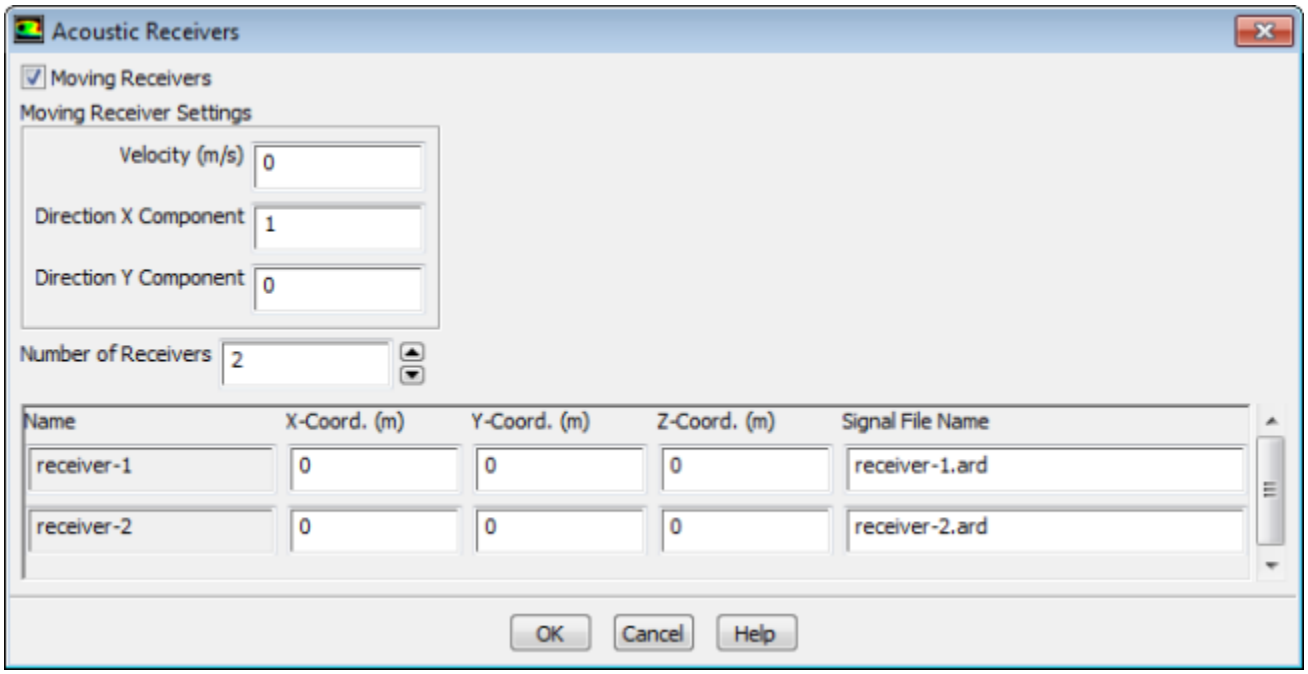
on the source surfaces you selected. ANSYS Fluent will print out the disk space requirement per time step at the time of source surface selection if the **Export Acoustic Source Data in ASD Format** option is enabled in the **Acoustics Model** dialog box.

At this point, if you have chosen to perform your acoustics calculation in two steps, (that is, saving the source data first, and computing the sound at a later time), you can go ahead and instruct ANSYS Fluent to perform a suitable number of time steps, and the source data will be saved to the disk. If you chose to perform an "on-the-fly" acoustic calculation, then you must specify receiver locations (see Specifying Acoustic Receivers (p. 1217)) before you run the unsteady ANSYS Fluent solution any further.

22.2.3. Specifying Acoustic Receivers

In the **Acoustics Model** dialog box, click the **Define Receivers...** button to open the **Acoustic Receivers** dialog box (Figure 22.7: The Acoustic Receivers Dialog Box (p. 1217)).

Figure 22.7: The Acoustic Receivers Dialog Box



Important

Note that you can also open the **Acoustic Receivers** dialog box by clicking the **Receivers...** button in the **Acoustic Sources** or the **Acoustic Signals** dialog box.

If required, you can enable **Moving Receivers** to specify the receiver motion. In this case, the defined **Velocity** magnitude and **Direction** apply to all receivers. The receiver locations, defined below, are then interpreted as the starting locations at the time that sound emission originates. The origination of sound emission is determined as follows:

- For "on the Fly" use of the FW-H model (see Computing Sound "on the Fly" (p. 1210)) the sound emission time is counted from the physical time of activation of the **Compute Acoustic Signals Simultaneously** option (see Figure 22.1: The Acoustics Model Dialog Box (p. 1209)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- When the FW-H model reads the previously written acoustic source data (see Reading Unsteady Acoustic Source Data (p. 1220)), the sound emission time starts from the physical time associated with the first selected source data file.

Important

When using moving receivers, note that if you start from a different source data file, this results in different receiver locations due to the different emission time origin associated with the different source data file.

Increase the **Number of Receivers** to the total number of receivers for which you want to compute sound, and enter the coordinates for each receiver in the **X-Coord.**, **Y-Coord.**, and **Z-Coord.** fields. Note that because ANSYS Fluent's acoustics model is ideally suited for far-field noise prediction, the receiver locations you define should be at a reasonable distance from the sources of sound (that is, the selected source surfaces). The receiver locations can also fall outside of the computational domain.

For each receiver, you can specify a file name in the **Signal File Name** field. These files will be used to store the sound pressure signals at the corresponding receivers. By default, the files will be named `receiver-1.ard`, `receiver-2.ard`, and so on.

Once the receiver locations have been defined, the setup for your acoustic calculation is complete.

22.2.4. Specifying the Time Step

When using an implicit-in-time solution algorithm (dual-time stepping), and depending on the physical time step size and the most important time scales in the flow, you can write the acoustic source data at every time step. You can also coarsen it in time by a given frequency factor. The highest possible frequency the acoustic analysis can generate is based on the time step size of the collected acoustic source data.

When using the **Density-Based** explicit solver, with the **Explicit Transient Formulation** selected in the **Solution Methods** task page, the physical time step must be computed by the solver, based on the CFL condition (Courant number). Due to the possibly large fluctuations of the physical time step, an adapting time-stepping procedure can be used when the FW-H acoustics model is enabled. This allows you to use a user-specified time interval for sampling the acoustic data. In turn, the solver adapts its time step, when necessary, without violating the CFL conditions to make sure that data is available at the desired time interval (hence, avoiding data interpolations).

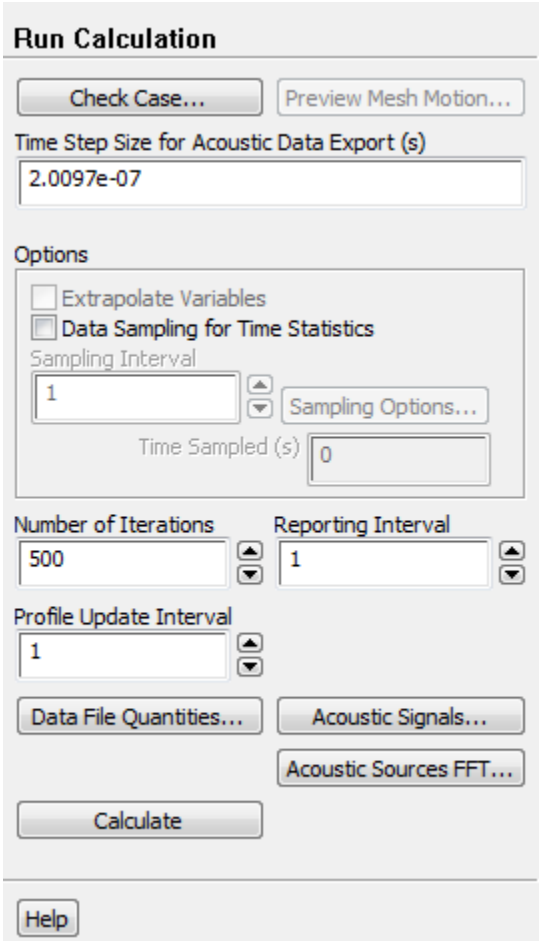
In the **Run Calculation** task page (Figure 22.8: The Run Calculation Task Page (p. 1219)), enter the **Time Step Size for Acoustic Data Export** to specify the time interval for acoustic data sampling. The value of this constant time step size determines the highest frequency that the acoustic analysis reproduces.

You can refer to Performing Time-Dependent Calculations (p. 1608) for more information about the **Run Calculation** task page.

Solution → **Run Calculation**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.8: The Run Calculation Task Page



You can now proceed to instruct ANSYS Fluent to perform a transient calculation for a suitable number of time steps. When the calculation is finished, you will have either the source data saved on files (if you chose to save it to a file or files), or the sound pressure signals (if you chose to perform an acoustic calculation "on the fly"), or both (if you chose to save the source data to files *and* if you chose to perform the acoustic calculation "on the fly").

If you chose to save the source data to files, the ANSYS Fluent console window will print a message at the end of each time step indicating that source data have been written (or appended to) a file (for example, `acoustic_example240.asd`).

22.2.5. Postprocessing the FW-H Acoustics Model Data

At this point, you will have either the source data saved to files or the sound pressure signals computed, or both. You can process these data to compute and plot various acoustic quantities using ANSYS Fluent's FFT capabilities. See Fast Fourier Transform (FFT) Postprocessing (p. 1873) for more information.

22.2.5.1. Writing Acoustic Signals

If you chose to perform the acoustic calculation "on the fly", you must write the sound pressure data to files. To do so, select **Write Acoustic Signals** under **Options** in the **Acoustic Signals** dialog box (Figure 22.9: The Acoustic Signals Dialog Box (p. 1220)) and then click **Write**. The computed acoustic pressure will be saved from internal buffer memory into a separate file for each receiver you defined in the **Acoustic Receivers** dialog box (for example, `receiver-1.ard`).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

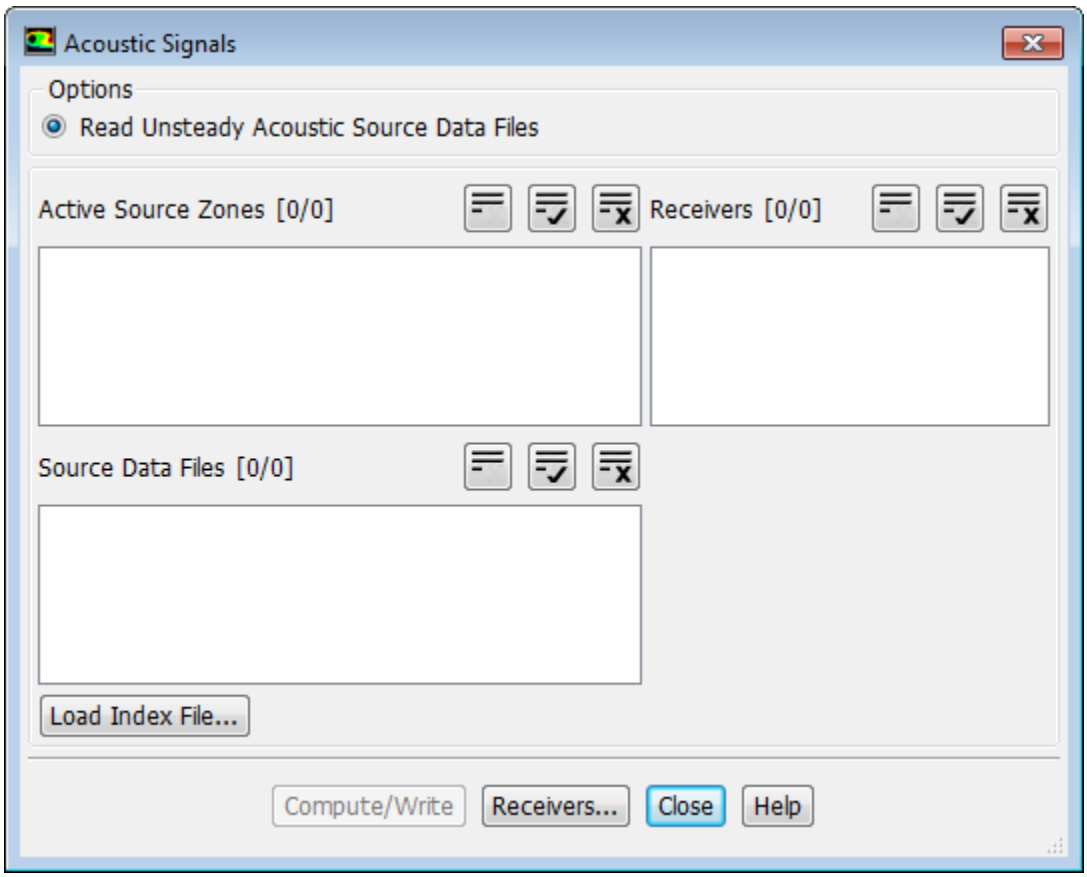
Solution → **Run Calculation** → **Acoustic Signals...**

22.2.5.2. Reading Unsteady Acoustic Source Data

Computing the sound pressure signals using the source data saved to files is done in the **Acoustic Signals** dialog box (Figure 22.9: The Acoustic Signals Dialog Box (p. 1220))

Solution → **Run Calculation** → **Acoustic Signals...**

Figure 22.9: The Acoustic Signals Dialog Box



To compute the sound data, use the following procedure:

1. In the **Acoustic Signals** dialog box, select **Read Unsteady Acoustic Source Data Files** under **Options**.
2. Click **Load Index File...** and select the index file for your computation in the **Select File** dialog box. The file will have the name you entered in the **Source Data Root File Name** field in the **Acoustic Sources** dialog box, followed by the `.index` suffix (for example, `acoustic_example.index`).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the **Source Data Files** list, select the source data files that you want to use to compute sound. Source data files will all contain the specified root file name followed by the suffix `.asd`.

   Important

   You can use any number of source data files. However, note that you should select only consecutive files.

4. In the **Active Source Zones** list, select the source zones you want to include to compute sound. See Specifying Source Surfaces (p. 1214) for details about proper source surface selection.

5. In the **Receivers** list, select the receivers for which you want to compute and save sound.

   Optionally, you can click the **Receivers...** button to open the **Acoustic Receivers** dialog box and define additional receivers.

6. Click the **Compute/Write** button to compute and save the sound pressure data. One file will be saved for each receiver you previously specified in the **Acoustic Receivers** dialog box (for example, `receiver-1.ard`).

   Important

   If you enabled both the **Export Acoustic Source Data in ASD Format** and **Compute Acoustic Signals Simultaneously** options in the **Acoustics Model** dialog box, you must first select the **Write Acoustic Signals** option in the **Acoustic Signals** dialog box after the flow simulation has been completed. If you select the **Read Unsteady Acoustic Source Data Files** before writing out the "on-the-fly" data in such a case, the data will be flushed out of the internal buffer memory. To avoid such a loss of data, you should save the ANSYS Fluent case and data files whenever you begin to do an acoustic computation in the **Acoustic Signals** dialog box. The sound pressure data calculated "on the fly" will then be saved into the `.dat` file. Finally, after the "on-the-fly" data is saved, make sure to change the file names of the receivers before doing a sound pressure calculation with the **Read Unsteady Acoustic Source Data Files** option enabled, to avoid overwriting the "on-the-fly" signal files.

   Important

   Note that you can compute and write sound pressure signals only when the FW-H acoustics model has been enabled. See Exporting Source Data Without Enabling the FW-H Model: Using the ANSYS Fluent ASD Format (p. 1212) for details about exporting source data (for example, for SYSNOISE) without enabling the FW-H model.

22.2.5.2.1. Pruning the Signal Data Automatically

Before the computed sound pressure data at each receiver is saved, it is by default automatically pruned. Pruning of the receiver data means clipping the tails of the signal where incomplete source information is available.

The acoustic source data is tabulated from time τ_0 to τ_n. Without auto-pruning, the receiver register begins receiving the earliest sound pressure signal at

$$t_0 = \tau_0 + \frac{r_{min}}{a_0} \tag{22.1}$$

where r_{min} is the shortest distance between the source surfaces and the receiver. However, the receiver will not receive the sound pressure signal from the farthest point on the source surfaces (r_{max}) until the receiver time becomes

$$t_1 = \tau_0 + \frac{r_{max}}{a_0} \tag{22.2}$$

From time t_0 to t_1, the sound accumulated on the receiver register does not include the contribution from the entire source surface area, and therefore the sound pressure data received during that time is not complete. The same thing occurs during the period from

$$t_m = \tau_m + \frac{r_{min}}{a_0} \tag{22.3}$$

to

$$t_n = \tau_n + \frac{r_{max}}{a_0} \tag{22.4}$$

Therefore, pruning means clipping the signal on the incomplete ends, from t_0 to t_1 and t_m to t_n. Auto-pruning can be disabled using the `define` → `models` → `acoustics` → `auto-prune` text command. Although auto-pruning can be disabled, it is expected that you will use only the complete sound pressure data.

22.2.5.3. Reporting the Static Pressure Time Derivative

The RMS value of the static pressure time derivative ($\partial p / \partial t$) is available for postprocessing only on wall surfaces, which are at the same time sources of sound, when the FW-H acoustics model is used.

You can select **Surface dpdt RMS** in the **Acoustics...** category only when you specify at least one wall surface, which is also marked as an acoustic source, in the relevant postprocessing dialog boxes.

22.2.5.4. Using the FFT Capabilities for Sound Pressure Signals

Once the sound pressure signals are computed and saved in files, the sound data is ready to be analyzed using ANSYS Fluent's FFT tools. In the **Fourier Transform** dialog box (Figure 31.89: The Fourier Transform Dialog Box (p. 1876)), click **Load Input File...** and select the appropriate `.ard` file. If the receiver data is still in ANSYS Fluent's memory, then it can directly be processed using the **Process Receiver** option. See Fast Fourier Transform (FFT) Postprocessing (p. 1873) for more information on ANSYS Fluent's FFT capabilities.

Results → **Plots** → **FFT** **Edit...**

22.2.6. FFT of Acoustic Sources: Band Analysis and Export of Surface Pressure Spectra

During a transient flow simulation, the time histories of the instant surface pressure values can be written into the binary acoustic source data (ASD) files. This operation is performed for all mesh cell faces of those surface zones that are selected as acoustic sources. The primary purpose of the ASD files is to supply input data for the Ffowcs-Williams and Hawkings acoustic solver (see Reading Unsteady Acoustic Source Data (p. 1220)). Additionally, these files can be used to visualize the spectral properties of the stored flow pressure signals. The supported spectral properties are the complex amplitudes for

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the individual Fourier modes, and the surface pressure level (SPL) values for the frequency bands, in decibels. Both the constant width and the proportional width bands (octaves and 1/3 octaves) can be specified.

Note

Despite the use of the common acronym "SPL", the calculated values characterize the transient flow pressure on a surface, and not the acoustic pressure; that is, in this context, the acronym refers to the "Surface Pressure Level" (as mentioned previously) and not the "Sound Pressure Level".

In addition to the visualization capabilities, with ANSYS Fluent you can also use the ASD files to export the computed spectrum fields of the flow pressure as CGNS files. The primary purpose of such files is to allow you to use the surface spectrum fields as distributed excitation forces when performing a harmonic response analysis with ANSYS Mechanical. The ability to import CGNS files is available in ANSYS Mechanical to match this export feature in Fluent; for details, see **FLUREAD** in the separate Mechanical APDL *Command Reference*. Using the acoustic wave equation solver of ANSYS Mechanical, it is possible to perform frequency domain simulations for applications such as the vehicle cabin noise caused by external turbulent flow.

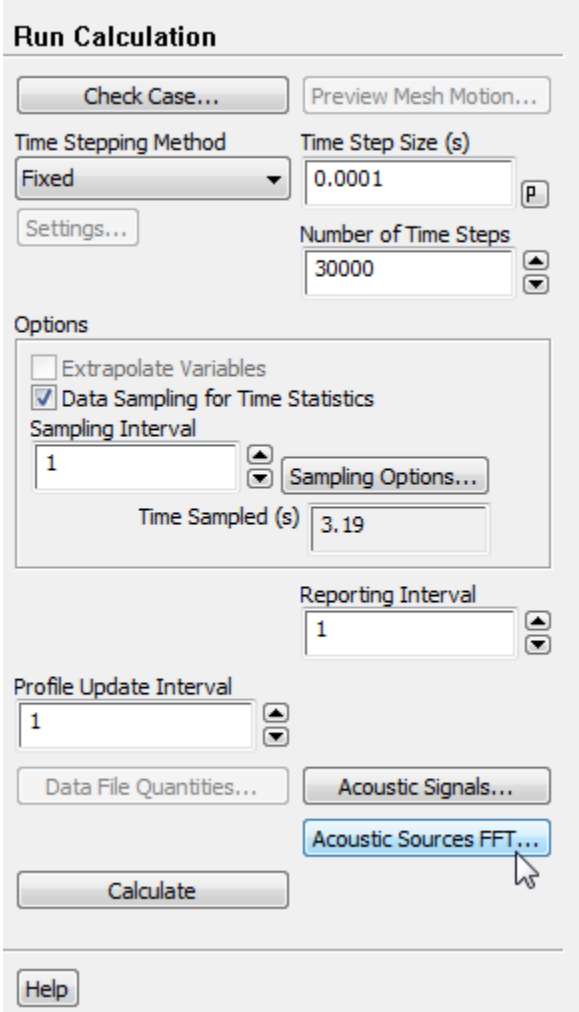
22.2.6.1. Using the FFT of Acoustic Sources

The **Acoustic Sources FFT…** button is available in the **Run Calculation** task page (as shown in Figure 22.10: The Run Calculation Task Page with the Acoustic Sources FFT… Button (p. 1224)) under the following conditions:

- The simulation is set up as a three-dimensional transient case.
- The **Export Acoustic Source Data in ASD Format** option is enabled in the **Acoustics Model** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.10: The Run Calculation Task Page with the Acoustic Sources FFT... Button



Clicking the **Acoustic Sources FFT...** button opens the **Acoustic Sources FFT** dialog box, which has four tabs (each of which is shown in the figures that follow):

- **Read ASD Files**
- **Compute FFT Fields**
- **FFT Surface Variables**
- **Write CGNS Files**

The first two tabs are obligatory, because the actions performed there prepare the Fourier spectra for the actions that follow, including creation of the surface variables to visualize (performed in the third tab) and/or CGNS export (performed in the fourth tab).

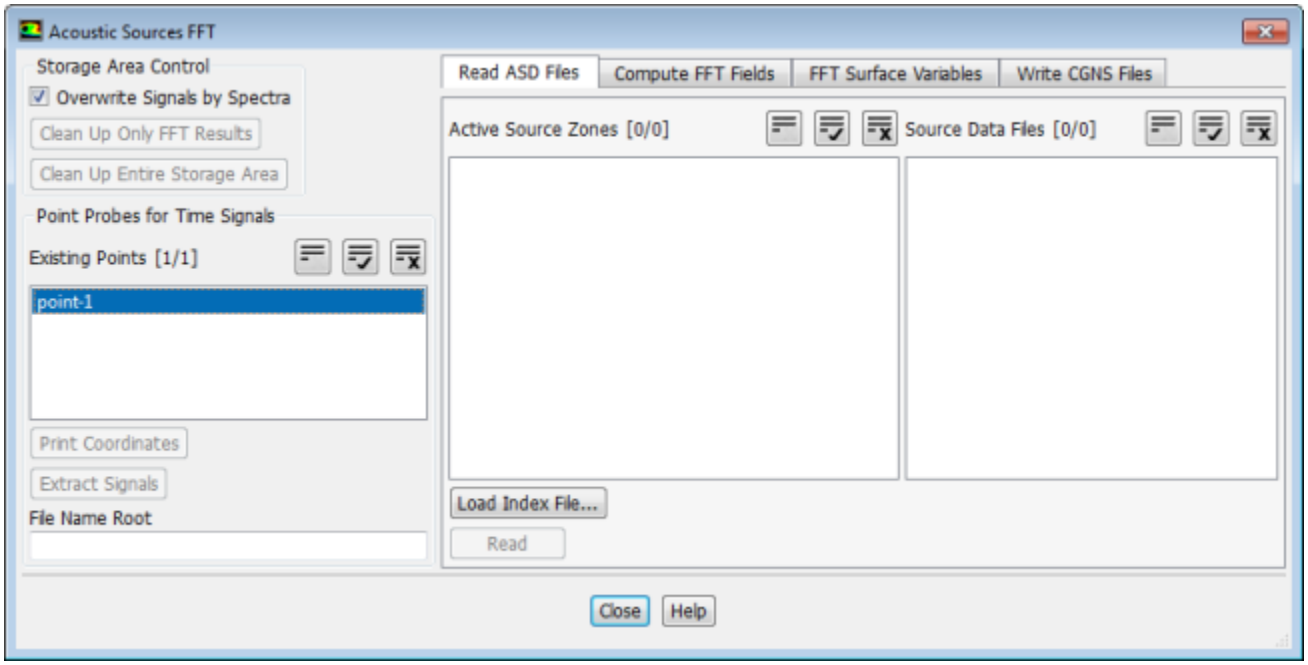
Postprocessing begins in the **Read ASD Files** tab. The **Active Source Zones** selection list shows all of the face zones for which transient export to ASD files has been performed (see Figure 22.11: The Read ASD Files Tab of the Acoustic Source FFT Dialog Box (p. 1225)). The **Source Data Files** selection list shows all of the available ASD files. Note that you can update this information by clicking the **Load Index File...** button and specifying the name of the index file to be read; the index file was created during the ASD files export, and is an ASCII file containing a list of the source zones and a list of the ASD file names. Select in the selection lists the desired face zones as well as the desired ASD files from which

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

you want to read, and click the **Read** button. The console displays information about the data, such as the following example:

```
Overall 10000 timesteps have been read
from 3.0001 s to 4 s
Time step is 0.0001 s
```

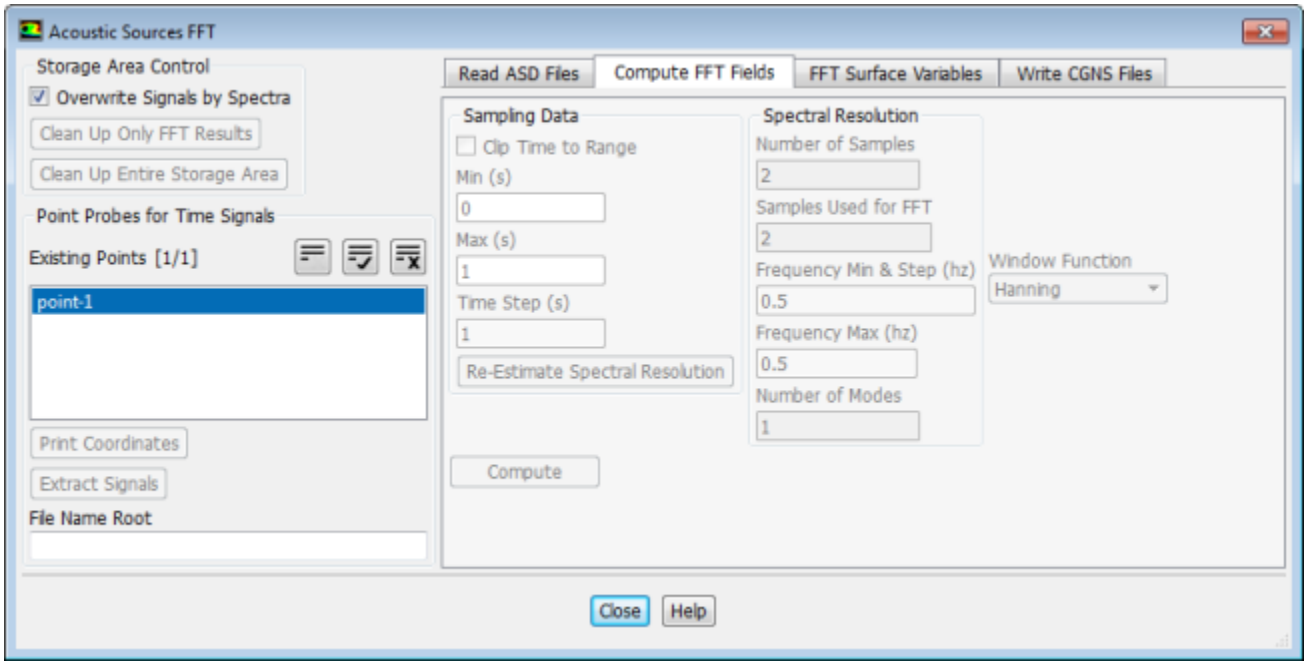
Figure 22.11: The Read ASD Files Tab of the Acoustic Source FFT Dialog Box



Having read the pressure histories, open the **Compute FFT Fields** tab (Figure 22.12: The Compute FFT Fields Tab of the Acoustic Source FFT Dialog Box (p. 1226)). The values shown in the **Spectral Resolution** group box provide information about the statistical properties, which depend on the sampling rate (that is, the simulation time step) and the signal length (that is, the simulation time). These values will change if you enable the **Clip Time to Range** option in the **Sampling Data** group box, reduce the time range for the signals by changing the **Min** and/or **Max** fields, and click the **Re-Estimate Spectral Resolution** button. The **Window Function** selection list allows you to specify a window function using the same choices that are available for plotting the single signal FFT in the **Plot/Modify Input Signal** dialog box. The default settings use the full signals and the Hanning window function. The FFT calculation begins when you click the **Compute** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.12: The Compute FFT Fields Tab of the Acoustic Source FFT Dialog Box



The fields of the pressure histories and the computed fields of the Fourier spectra are stored in a large memory array, referred to here as the "storage area". This memory is allocated by Fluent dynamically when you read the pressure signals from the ASD files. If you read data for all face zones available in the ASD files, and if they are the wall zones, then the size of the allocated storage area is equal to the total size of the ASD files being read. Since the same or a slightly smaller amount of data is produced by the FFT algorithm, the same storage area can be re-used to store the Fourier spectra without allocating additional memory. Alternatively, the pressure histories can be left intact in memory, and for their spectra the storage area is correspondingly increased.

These two modes of memory allocation are controlled by the **Overwrite Signals by Spectra** option in the **Storage Area Control** group box. When the **Overwrite Signals by Spectra** option is enabled, the Fourier spectra displace in memory the original time signals, which are not kept after the FFT has been computed. Therefore, if you want to re-compute the FFT using the **Clip Time to Range** tool or a different **Window Function** (which are both in the **Compute FFT Fields** tab), you have to first de-allocate the storage area by clicking the **Clean Up Entire Storage Area** button, and then re-read the pressure histories from the ASD files. When the **Overwrite Signals by Spectra** option is disabled, you can re-compute the FFT without re-reading the pressure histories, as many times as you want. To do this, click the **Clean Up Only FFT Results** button, and proceed with computing spectra from the available pressure histories. De-allocation of the storage area (which can be very large) is recommended when you are done using the **Acoustic Sources FFT** dialog box and plan to either proceed to other postprocessing work or continue your transient simulation without re-starting Fluent.

When the pressure histories are read and kept in the storage area, you can create point probes within the surface zones that have been read and extract the single pressure time signals at these probes. The extracted signals and their spectra may help to analyze the transient flow properties. For example, by creating an XY plot of a signal, you can figure out the need for clipping of the sampling time; by creating an XY plot of its spectrum, you can detect the presence of the tonal noise components.

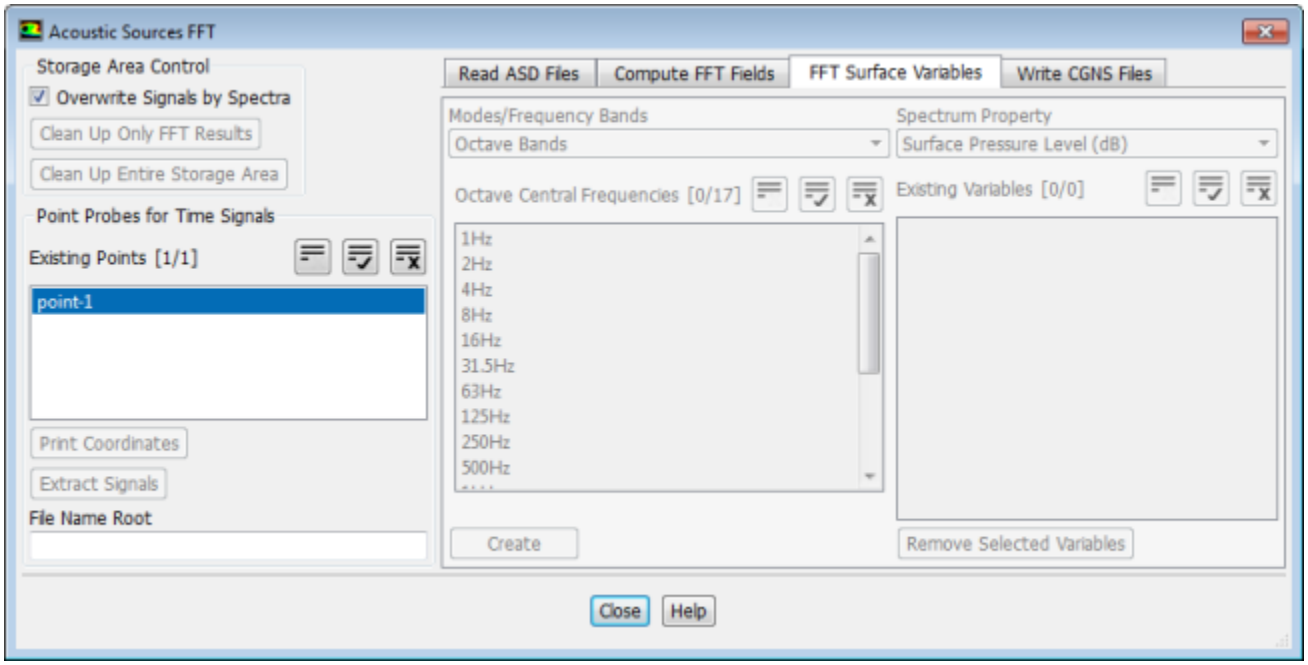
To create a point probe, open the Point Surface Dialog Box (p. 2780) by clicking **Create** and selecting **Point...** in the **Setting Up Domain** ribbon tab (**Surface** group box), and create a point surface by any available method (for example, by specifying the coordinates). The point probe will be created at the face center that is nearest to the point surface on the read surface zones. The created point probes are

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

then listed under the point surface names in the **Existing Points** selection list, which is located in the **Point Probes for Time Signals** group box. You can print the coordinates of the point probes to the Fluent console by selecting the desired probes and clicking the **Print Coordinates** button. Clicking the **Extract Signals** button outputs the pressure histories for the selected probes in the ASCII files; these files can then be analyzed using the Fourier Transform Dialog Box (p. 2602) (available from the Plots Task Page (p. 2593)) by selecting **Process File Data** and then reading the exported ASCII file using the **Load Input File...** button. The exported files names are by default the point probe names with the extension `.dat`. The **File Name Root** field allows you to specify a prefix for these file names.

The **FFT Surface Variables** tab is shown in Figure 22.13: The FFT Surface Variables Tab of the Acoustic Source FFT Dialog Box for the Octave Bands (p. 1227) and Figure 22.14: The FFT Surface Variables Tab of the Acoustic Source FFT Dialog Box for a Set of Individual Modes (p. 1228). This tab allows you to **Create** new Fluent variables using the computed spectrum fields, which reside in the storage area and correspondingly increase its size. These variables will be defined only on those wall face zones for which the Fourier transformation has been computed; on the other face zones, they will show zero values. Created variables can be used for any kind of further postprocessing in Fluent, which typically includes contour plotting (see the variables marked with the restriction *asfft* in Table 33.17: **Acoustics** Category (p. 1956)) or exporting to CFD-Post.

Figure 22.13: The FFT Surface Variables Tab of the Acoustic Source FFT Dialog Box for the Octave Bands



Variables may characterize either the individual Fourier modes (if you select **Set of Modes** from the **Modes/Frequency Bands** drop-down list), or frequency bands that each represent a range of frequencies (if you select the other choices in the **Modes/Frequency Bands** drop-down list). The three types of frequency bands that are available include:

- **Octave Bands**

  These are proportional bands corresponding to the standard technical octaves.

- **1/3 Octave Bands**

  These are proportional bands corresponding to the standard technical thirds.

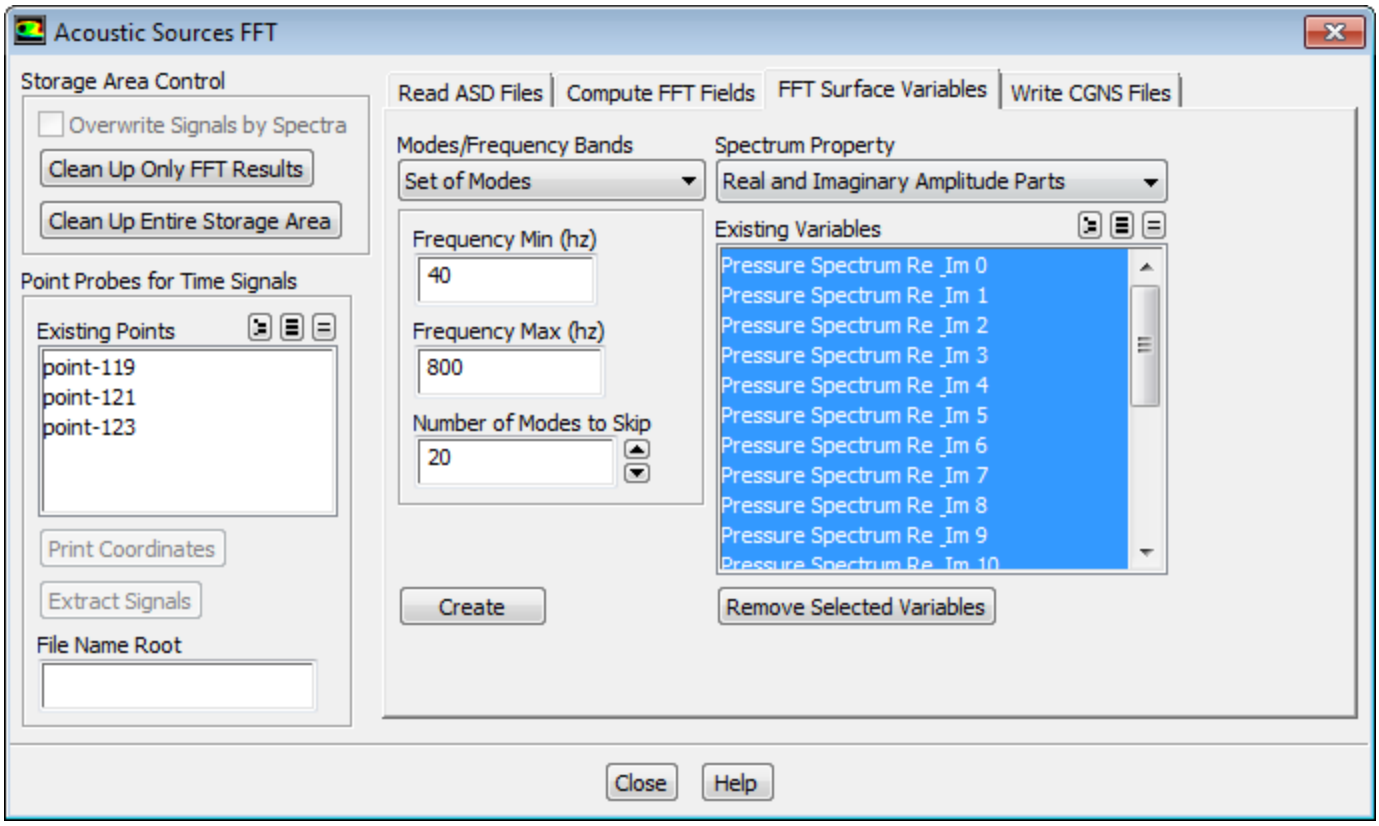
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Constant Width Bands**

  These are user-defined equidistant bands.

The **Spectrum Property** drop-down list displays the type of variables created according to the selected choice in the **Modes/Frequency Bands** drop-down list. For a set of modes, the created variables are the real and the imaginary parts of the complex Fourier amplitudes, with a pair of variables per specified mode. For the frequency bands, the created variables are the surface pressure level (SPL) fields, in decibels. The transformation to the decibel units is done by default using the standard acoustic reference pressure value of 2×10^{-5} Pa; you can change this value before creating the variables by opening the **Acoustic Models** dialog box, selecting the **Ffowcs-Williams & Hawkings** model, and revising the **Reference Acoustic Pressure**.

Figure 22.14: The FFT Surface Variables Tab of the Acoustic Source FFT Dialog Box for a Set of Individual Modes



The allowed number of variables makes it possible for you to simultaneously keep SPL for all octave and 1/3 octave bands, as well as SPL for up to 20 constant width bands and the real and imaginary amplitudes for up to 20 individual frequencies. The SPL variables for the octaves and the 1/3 octaves include the band central frequency in their names (for example, **SPL for Octave Band at 250Hz (dB)** or **SPL for 1/3-Octave Band at 1.25kHz (dB)**). As for the user-defined frequencies and constant width bands, their variables are simply numbered from 0 to 19. In order to provide you with the information about the meaning of each such variable, Fluent prints a table in the console when you click **Create**. The following is an example of the table corresponding to the settings in the previous figure:

```
Creating variables for 20 modes from 40.5983 Hz to 466.88 Hz every 22.4359 Hz.
f( 0) = 40.5983 Hz     f( 1) = 63.0342 Hz
f( 2) = 85.4701 Hz     f( 3) = 107.906 Hz
f( 4) = 130.342 Hz     f( 5) = 152.778 Hz
f( 6) = 175.214 Hz     f( 7) = 197.65 Hz
f( 8) = 220.085 Hz     f( 9) = 242.521 Hz
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
f(10) = 264.957 Hz     f(11) = 287.393 Hz
f(12) = 309.829 Hz     f(13) = 332.265 Hz
f(14) = 354.701 Hz     f(15) = 377.137 Hz
f(16) = 399.573 Hz     f(17) = 422.009 Hz
f(18) = 444.444 Hz     f(19) = 466.88 Hz

Variables for frequencies above 466.88 Hz are not created,
because the limit of 20 modes has been reached.
```

You can analyze more than 20 individual modes or constant width bands, if you process them by portions of 20 items and delete the processed variables by selecting them in the **Existing Variables** list and clicking the **Remove Selected Variables** button.

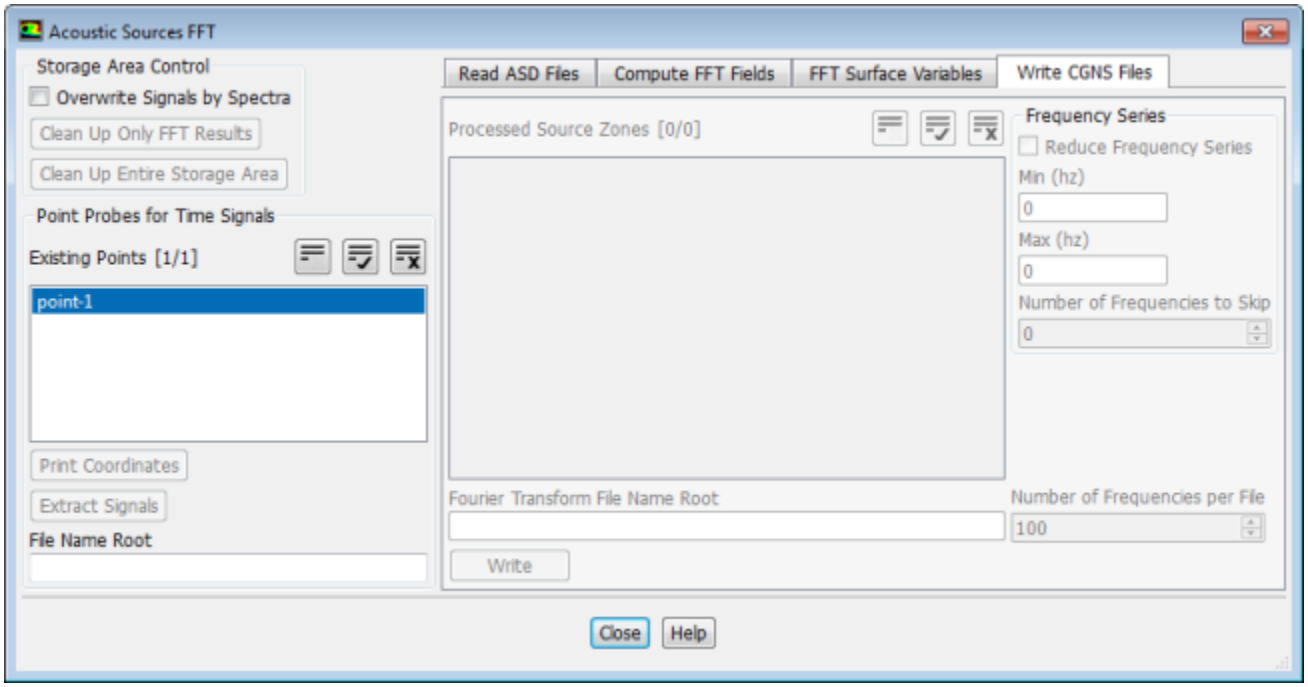
Clicking either the **Clean Up Entire Storage Area** or the **Clean Up Only FFT Results** button on the left side of the dialog box not only de-allocates the spectrum storage array, but also removes all created variables.

The **Write CGNS Files** tab is shown in Figure 22.15: The Write CGNS Files Tab of the Acoustic Source FFT Dialog Box (p. 1230). This tab allows you to specify the zones you want to export to CGNS, by selecting them in the **Processed Source Zones** list. You can reduce the exported spectrum data by enabling the **Reduce Frequency Series** option and specifying the frequency range (**Min** and **Max** frequencies), as well as the frequency step (the **Number of Frequencies to Skip** integer field). The latter must be used with care and only if really needed, because the Fourier amplitudes in the broadband noise spectrum depend on the frequency resolution. By skipping frequencies from the exported spectrum (for example, exporting every other Fourier mode), you will artificially coarsen the frequency resolution. However, the exported amplitudes will not be automatically re-scaled for the increased frequency step, but will retain their originally computed values.

Pressure spectra, which result from the scale-resolving flow simulations, may contain thousands of frequencies. Together with dense surface meshes, this can result in a very large amount of data to export. The total size of the disk space required to store fields of the complete spectra is approximately equal to the total size of the ASD files containing the wall pressure histories. Therefore, the wall pressure spectra are written to a series of CGNS files according to the **Number of Frequencies per File** field. It is recommended that you select an appropriate value for this parameter, to avoid extremely large output files or a large number of very small files. The total number of frequencies in the spectrum can be seen in the **Number of Modes** field of the **Compute FFT Fields** tab (see Figure 22.12: The Compute FFT Fields Tab of the Acoustic Source FFT Dialog Box (p. 1226)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 22.15: The Write CGNS Files Tab of the Acoustic Source FFT Dialog Box



Finally, you can specify a name root for the exported CGNS files in the **Fourier Transform File Name Root** field. For example, if you enter `wall_pressure_spectrum` and then click the **Write** button, Fluent will create the following set of files in your working folder:

wall_pressure_spectrum.cgns

wall_pressure_spectrum_1.cgns

wall_pressure_spectrum_2.cgns

...

wall_pressure_spectrum.flst

If you leave the name root field empty, the files will be named **cgns**, **1.cgns**, **2.cgns**, **...**, **flst**. The first CGNS file (without a number in its name) contains the mesh data, as well as links to all of the other CGNS files, which in turn contain the spectrum fields with the specified number of modes per file. The CGNS links work like the file links in the UNIX file system: in order to import spectra to the ANSYS Mechanical software, you only have to specify the name of the first file, and all other files will be imported automatically if they reside in the same folder. The file with the extension **flst** is an ASCII file, which contains the list of the exported frequencies.

Important

Note the following:

- You should not specify a relative path as a part of the **Fourier Transform File Name Root** input. If you do that, all files will be exported in the desired folder according to the specified path. However, the CGNS links, which are written in the first CGNS file, will also include the specified path. Therefore, the linked CGNS files will become readable only after the correspondent file re-location—for example, moving the first CGNS file in your Fluent working folder.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The public domain CGNS library, which is used to process CGNS files in Fluent and ANSYS Mechanical, has a performance issue when run on Windows. Namely, for CGNS files that have many links (as is the case in this application), the input / output operations may be very slow if the CGNS files are located on a network disk. Therefore, for Windows it is strongly recommended that you select either a built-in local disk or a USB disk directly connected to your computer as the location of the CGNS files. This warning concerns both the export of CGNS files from Fluent and their import in ANSYS Mechanical.

22.3. Using the Broadband Noise Source Models

In this section, the procedure for setting up and using the broadband noise source models is outlined first, followed by descriptions of each of the steps involved.

The general procedure for carrying out a broadband noise source calculation in ANSYS Fluent is as follows:

1. Calculate a steady or unsteady RANS solution.

2. Enable the broadband noise model and set the associated model parameters.

   Setup → **Models** → **Acoustics** **Edit...**

3. Postprocess the noise sources.

   Results → **Graphics** → **Contours** **Edit...**

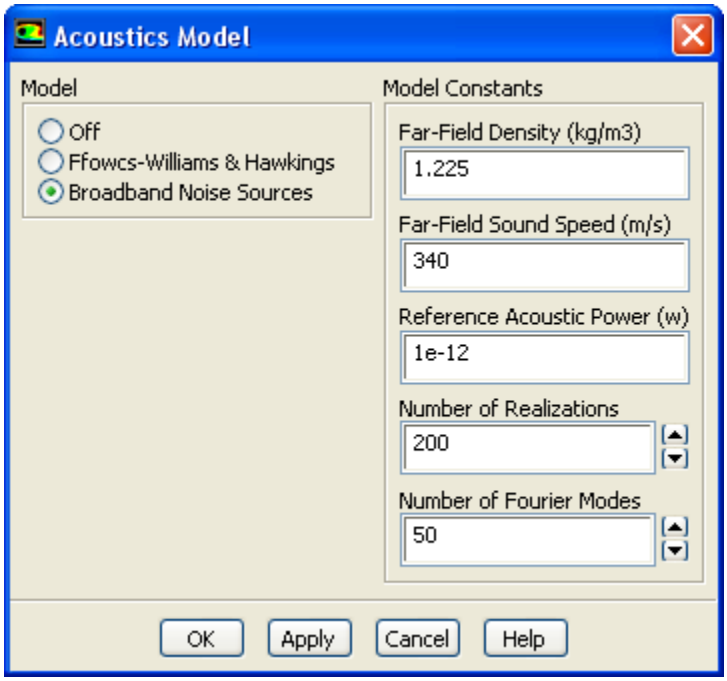
For additional information, see the following sections:
22.3.1. Enabling the Broadband Noise Source Models
22.3.2. Postprocessing the Broadband Noise Source Model Data

22.3.1. Enabling the Broadband Noise Source Models

To enable the broadband noise sources models, select **Broadband Noise Sources** in the **Acoustics Model** dialog box (Figure 22.16: The Acoustics Model Dialog Box for Broadband Noise (p. 1232)).

Setup → **Models** → **Acoustics** **Edit...**

Figure 22.16: The Acoustics Model Dialog Box for Broadband Noise



22.3.1.1. Setting Model Constants

Under **Model Constants** in the **Acoustics Model** dialog box, specify the relevant acoustic parameters and constants used by the model. See Enabling the FW-H Acoustics Model (p. 1208) for the definitions of **Far-Field Density** and **Far-Field Sound Speed**.

Reference Acoustic Power
(for example, P_{ref} in Equation 15.14 in the Theory Guide) is used to compute the acoustic power outputs in decibels (dB). The default value is 10^{-12}. Note that the units for the reference acoustic power will be different in 2D (W/m^2) and 3D (W/m^3) cases.

Number of Realizations
is the number of samples used in the SNGR to compute the averaged source terms of LEE and Lilley's equations. The default value is 200.

Number of Fourier Modes
(N in Equation 15.34 in the Theory Guide) is the number of the Fourier modes used to compute the turbulent velocity field and its derivatives. The turbulent velocity field is then used to compute the LEE and Lilley's source terms. The default value is 50.

22.3.2. Postprocessing the Broadband Noise Source Model Data

The final step in the broadband noise source modeling process is the postprocessing of acoustic power and noise source data. The following variables are available in the **Acoustics...** postprocessing category:

- **Acoustic Power Level (dB)**
- **Acoustic Power**
- **Jet Acoustic Power Level (dB)** (axisymmetric models only)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Jet Acoustic Power** (axisymmetric models only)
- **Surface Acoustic Power Level (dB)**
- **Surface Acoustic Power**
- **Lilley's Self-Noise Source**
- **Lilley's Shear-Noise Source**
- **Lilley's Total Noise Source**
- **LEE Self-Noise X-Source**
- **LEE Shear-Noise X-Source**
- **LEE Total Noise X-Source**
- **LEE Self-Noise Y-Source**
- **LEE Shear-Noise Y-Source**
- **LEE Total Noise Y-Source**
- **LEE Self-Noise Z-Source** (3D models only)
- **LEE Shear-Noise Z-Source** (3D models only)
- **LEE Total Noise Z-Source** (3D models only)

Chapter 23: Modeling Discrete Phase

This chapter describes how to use the Lagrangian discrete phase capabilities available in ANSYS Fluent. For information about the theory behind the discrete phase models, see Discrete Phase in the Theory Guide. Information is organized into the following sections:

23.1. Introduction
23.2. Steps for Using the Discrete Phase Models
23.3. Setting Initial Conditions for the Discrete Phase
23.4. Setting Boundary Conditions for the Discrete Phase
23.5. Setting Material Properties for the Discrete Phase
23.6. Solution Strategies for the Discrete Phase
23.7. Postprocessing for the Discrete Phase
23.8. Parallel Processing for the Discrete Phase Model

23.1. Introduction

In addition to solving transport equations for the continuous phase, ANSYS Fluent allows you to simulate a discrete second phase in a Lagrangian frame of reference. This second phase consists of spherical particles (which may be taken to represent droplets or bubbles) dispersed in the continuous phase. ANSYS Fluent computes the trajectories of these discrete phase entities, as well as heat and mass transfer to/from them. The coupling between the phases and its impact on both the discrete phase trajectories and the continuous phase flow can be included.

ANSYS Fluent provides the following discrete phase modeling options:

- calculation of the discrete phase trajectory using a Lagrangian formulation that includes the discrete phase inertia, hydrodynamic drag, and the force of gravity, for both steady and unsteady flows
- prediction of the effects of turbulence on the dispersion of particles due to turbulent eddies present in the continuous phase
- heating/cooling of the discrete phase
- vaporization and boiling of liquid droplets
- combusting particles, including volatile evolution and char combustion to simulate coal combustion
- optional coupling of the continuous phase flow field prediction to the discrete phase calculations
- droplet breakup and coalescence
- consideration of particle/particle collisions and voidage of discrete phase

These modeling capabilities allow ANSYS Fluent to simulate a wide range of discrete phase problems including particle separation and classification, spray drying, aerosol dispersion, bubble stirring of liquids, liquid fuel combustion, and coal combustion. The physical equations used for these discrete phase calculations are described in Discrete Phase in the *Fluent Theory Guide*, and instructions for setup, solution, and postprocessing are provided in the remaining sections of this chapter.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Alternative models for multiphase systems use the Euler-Euler approach rather than the Euler-Lagrange approach used in the Discrete Phase Model. The Euler-Euler models are discussed in Modeling Multiphase Flows (p. 1365) along with the Dense Discrete Phase Model which is a hybrid Euler-Euler and Euler-Lagrange approach.

For additional information, see the following sections:

23.1.1. Concepts
23.1.2. Limitations

23.1.1. Concepts

This section introduces several concepts in the treatment of discrete phase particles in Fluent that are important to understand in order to get the most out of the remaining information in this chapter.

23.1.1.1. Uncoupled vs. Coupled DPM
23.1.1.2. Steady vs. Unsteady Tracking
23.1.1.3. Parcels

23.1.1.1. Uncoupled vs. Coupled DPM

When the fluid changes the particles, there will be corresponding effects on the fluid. For example, when drag force acts on a particle, the exchange of momentum can change the fluid flow. When simulating particles using DPM, you can choose whether or not to include these effects in the flow solution; these alternatives are called Coupled and Uncoupled DPM. See Options for Interaction with the Continuous Phase (p. 1241) for details about how to specify whether your simulation uses Coupled or Uncoupled DPM.

In Uncoupled DPM, the only purpose of the DPM particles is for postprocessing, and so particles are not tracked except when you request them, for example to calculate and display particle tracks. The particles can still change by heat and mass transfer, but the corresponding changes (such as vapor from an evaporating droplet) do not affect the flow solution.

In a Coupled DPM simulation, the effects of the particles are used to influence the flow solution. These effects are transmitted to the flow as DPM Sources. The DPM solution and the flow solution should reach a converged, self-consistent solution. Therefore, there are several options for running these solutions together—see Solution Strategies for the Discrete Phase (p. 1325).

23.1.1.2. Steady vs. Unsteady Tracking

As described in Steps for Using the Discrete Phase Models (p. 1240), to set up a DPM simulation you specify the starting conditions of a set of particles by defining an injection. By specifying boundary conditions and physical sub-models, you also specify how these particles interact with other zones in the geometry and how they eventually leave the model—for instance, they might bounce off some walls but be trapped by others.

You must also specify how Fluent is to track the particles you have defined. If Steady Tracking is enabled, then, as soon as a particle is released, it is tracked until it reaches its final destination according to the specified boundary behavior (or until a fixed number of particle time steps have been used). Therefore, each particle typically travels through many cells of the model, interacting with the flow and (in a Coupled DPM simulation) changing the DPM Sources in each cell. These sources influence the flow solution for a defined number of iterations or time steps—the flow solution can be steady or unsteady. Then, if required, a new set of particle trajectories is tracked, the DPM Sources are updated, and the sequence is repeated. An example of using Steady DPM with unsteady flow is when the chosen flow models require a transient simulation, although the final goal is a steady solution.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If Unsteady Tracking is enabled, then each particle is advanced by a specified number of particle time steps, not necessarily reaching a final destination, before the flow solution is updated. When Unsteady DPM is coupled to unsteady flow solution, the particles and the flow develop in time together concurrently, although different time steps can be used for DPM and flow.

Unsteady DPM can also be coupled to steady flow solution; this makes sense if there is a continuous source of DPM particles that pass through the system. For steady or unsteady flow, there are several DPM models where Unsteady Tracking is required. For example, in spray coalescence and collision models, particles change with time on the basis of interactions with other particles, so they must be tracked simultaneously

23.1.1.3. Parcels

Especially when using Coupled DPM, the mass flow rate of a particle injection will often be a required and relevant input parameter since it determines the absolute value of the DPM Sources. This mass flow rate could be converted into the number of particles injected per unit time. However, it is often prohibitive to track that number of particles in a simulation. Strictly speaking, the model therefore tracks a number of 'parcels', and each parcel is representative of a fraction of the total continuous mass flow rate (in Steady tracking) or a fraction of the total mass flow released in a time step (in Unsteady tracking).

It is still sometimes helpful to refer to each parcel as a representative particle, because it has a specified particle diameter, and its trajectory in fluid flow uses the relaxation time appropriate for a single particle. (The relaxation time is a ratio of particle momentum to drag force). However, the parcel's mass (or mass flow rate) becomes important when calculating the DPM Sources: for example, if a representative droplet loses a small amount of vapor by evaporation, the overall effect from the whole parcel will typically be much larger. Other models also use the parcel mass (or mass flow rate) to calculate total concentrations of DPM material—in particular, the Dense Discrete Phase Model uses this concentration to feed into the volume fraction of the Eulerian phase that represents the same material. See Dense Discrete Phase Model in the *Fluent Theory Guide* for details of the Dense Discrete Phase Model

The concept of parcels is particularly important in the Discrete Element Method (DEM), where parcels occupy a finite volume and obstruct other DEM parcels. The volume occupied by a parcel is calculated directly from the mass that it represents (so that a realistic density is created when parcels pack together). The equivalent 'parcel diameter' is used for calculating parcel-parcel contacts and forces. However, for trajectories through fluid, it is still the 'particle diameter' that is used. See Discrete Element Method Collision Model in the *Fluent Theory Guide* for details of the Discrete Element Model.

The number of parcels in a DPM model is chosen in the model settings, and not defined by the true number of particles. There are several inputs that can be used to adjust the number of parcels when defining initial conditions such as the number of injection locations and (for Unsteady Tracking) the injection frequency (Setting Initial Conditions for the Discrete Phase (p. 1265)) Other inputs in sub-models include: the number of sizes in a size distribution (Using the Rosin-Rammler Diameter Distribution Method (p. 1281)); the number of stochastic tries in turbulent dispersion (Specifying Turbulent Dispersion of Particles (p. 1294)); and the breakup characteristics of some sprays (Breakup (p. 1292)). A high number of parcels can be computationally expensive, but it is often helpful for convergence, so that no single parcel has an overwhelming effect on the flow In general you should arrange for enough parcels to produce a statistical sample, representative of the full range of particle behavior.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.1.2. Limitations

23.1.2.1. Limitation on the Particle Volume Fraction

The discrete phase formulation used by ANSYS Fluent contains the assumption that the second phase is sufficiently dilute that particle-particle interactions and the effects of the particle volume fraction on the gas phase are negligible. In practice, these issues imply that the discrete phase must be present at a fairly low volume fraction, usually less than 10–12%. Note that the mass loading of the discrete phase may greatly exceed 10–12%: you may solve problems in which the mass flow of the discrete phase equals or exceeds that of the continuous phase. See Modeling Multiphase Flows (p. 1365) for information about when you might want to use one of the general multiphase models instead of the discrete phase model.

This limitation is relaxed for some variants of DPM For example, the Dense Discrete Phase Model adds effects due to friction and volume fraction, so that the concentration can approach the packing limit Where high local concentrations of spray droplets cause coalescence and collision, these phenomena can be included in some spray models Parcel-parcel contacts between solid particles are modeled in detail in Discrete Element Models, so that parcels can pack together closely.

23.1.2.2. Limitation on Modeling Continuous Suspensions of Particles

The steady-particle Lagrangian discrete phase model is suited for flows in which particle streams are injected into a continuous phase flow with a well-defined entrance and exit condition. The Lagrangian model does not effectively model flows in which particles are suspended indefinitely in the continuum, as occurs in solid suspensions within closed systems such as stirred tanks, mixing vessels, or fluidized beds. The unsteady-particle discrete phase model, however, is capable of modeling continuous suspensions of particles. See Modeling Multiphase Flows (p. 1365) for information about when you might want to use one of the general multiphase models instead of the discrete phase models.

23.1.2.3. Limitations on Modeling Particle Rotation

When using rotating particles, note the following limitations:

- In simulations with enabled stochastic particle collision models (Including Collision and Droplet Coalescence (p. 1252)), particle rotation is not affected by particle/particle collisions.
- Particle rotation is not available for massless particles.
- Particle rotation is not compatible with moving reference frame simulations.
- For atomizer injections, the initial angular velocity is set to zero.
- The effect of the Magnus lift force on the fluid is not taken into account in DPM coupled simulations.

23.1.2.4. Limitations on Using the Discrete Phase Model with Other ANSYS Fluent Models

The following restrictions exist on the use of other models with the discrete phase model:

- When tracking particles in parallel, the DPM model cannot be used with any of the multiphase flow models (VOF, mixture, or Eulerian—see Modeling Multiphase Flows (p. 1365)) if the shared memory option is enabled (Parallel Processing for the Discrete Phase Model (p. 1360)). (Note that using the message passing or hybrid

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

option, when running in parallel, enables the compatibility of all multiphase flow models with the DPM model.)

- When using the DPM model with the Eulerian multiphase model, the tracked particles rely only on the primary phase to compute drag, heat, and mass transfer. Also, any DPM related source terms are applied to the primary phase. Particle tracking relative to a secondary phase is not provided.
- Streamwise periodic flow (either specified mass flow rate or specified pressure drop) cannot be modeled with steady particle tracks in coupled simulation. It is possible using transient particle tracks.
- Only non-reacting particles can be included when the premixed combustion model is used.
- Surface injections will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used, however only those surfaces associated with a boundary will be recalculated. Injections from cut plane surfaces will not be moved with the mesh and will be deleted when remeshing occurs.
- The cloud model is not available for unsteady particle tracking, or in parallel, when using the message passing or hybrid option for the particles.
- The wall film model is only valid for liquid materials. If a nonliquid particle interacts with a wall film boundary, the boundary condition will default to the reflect boundary condition.
- When multiple reference frames are used in conjunction with the discrete phase model, the display of particle tracks will not, by default, be meaningful. Similarly, coupled discrete-phase calculations are not meaningful.

  An alternative approach for particle tracking and coupled discrete-phase calculations with multiple reference frames is to track particles based on absolute velocity instead of relative velocity. To make this change, use the `define/models/dpm/ options/track-in-absolute-frame` text command. Note that the results may strongly depend on the location of walls inside the multiple reference frame.

  The particle injection velocities (specified in the **Set Injection Properties** dialog box) are defined relative to the frame of reference in which the particles are tracked. By default, the injection velocities are specified relative to the local reference frame. If you enable the `track-in-absolute-frame` option, the injection velocities are specified relative to the absolute frame.
- Relative particle tracking cannot be used in combination with sliding and moving deforming meshes. If sliding and/or deforming meshes are used with the DPM model, the particles will always be tracked in the absolute frame. Switching to the relative frame is not permitted.

23.1.2.5. Limitations on Using the Hybrid Parallel Method

- The hybrid parallel DPM tracking method is not available with the following models and features:
  - the PDF Transport model
  - the DDPM (Dense DPM) model with the **Volume Fraction Approaching Packing Limit** option selected in the **Discrete Phase** dialog box
  - the **Stochastic Collision** model (with or without the droplet coalescence)
  - Graphical display of particle tracks
  - Sampling of particle tracks in sample files

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  – Export of particle tracks into particle history files

  If any of these models or features are used, Fluent will silently fall back to the **Message Passing** parallel DPM tracking option.

- The **Use DPM Domain** option of the **Hybrid** parallel DPM tracking mode will not be used in any of the following situations:

  – if the **Update DPM Sources Every Flow Iteration** option is enabled

  – if the **Contour Plots for DPM Variables** option is enabled

  – if the **Enable Node Based Averaging** option (under the **Numerics** tab) is enabled

  – if the case includes non-zonal surface injections (that is, injections that have positions defined through surfaces that are not zone surfaces)

  – if the case includes a wall / shadow pair

  – if you are not running with distributed memory on a cluster

  If the **Use DPM Domain** option is enabled in such cases, ANSYS Fluent will issue a message warning that the DPM Domain is suppressed. You can avoid this message by disabling the **Use DPM Domain** option in the **Parallel** tab of the **Discrete Phase Model** dialog box.

  For additional limitations associated with the hybrid parallel method, see Limitations on Using the Discrete Phase Model with Other ANSYS Fluent Models (p. 1238).

23.1.2.6. Limitations on Using the Lagrangian Wall Film Model

- The Lagrangian wall film model is only available with **Unsteady Particle Tracking**.

- The Lagrangian wall film model is not compatible with hanging-node mesh refinement on walls. Though the fluid meshes can be adapted, the refined meshes must not touch walls where the wall film model is enabled.

- The wall film model assumes liquid particle materials. If an inert particle interacts with a wall film boundary, it is assumed to be liquid for the wall film model calculations. For combusting particles, the wall film is applied if **Wet Combustion Model** is enabled and as long as the liquid fraction in the particle is nonzero. If a dry combusting particle interacts with a wall film boundary it will stick to the wall and follow the combusting particle laws.

- The wall film model is not compatible with the Rosseland Radiation model.

- The **Workpile Algorithm** option is not available with the wall film boundary condition. It will be disabled automatically when choosing to simulate a wall film on a wall.

23.2. Steps for Using the Discrete Phase Models

You can include a discrete phase in your ANSYS Fluent model by defining the initial position, velocity, size, and temperature of individual particles. These initial conditions, along with your inputs defining the physical properties of the discrete phase, are used to initiate trajectory and heat/mass transfer calculations. The trajectory and heat/mass transfer calculations are based on the force balance on the particle and on the convective/radiative heat and mass transfer from the particle, using the local con-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

tinuous phase conditions as the particle moves through the flow. The predicted trajectories and the associated heat and mass transfer can be viewed graphically and/or alphanumerically.

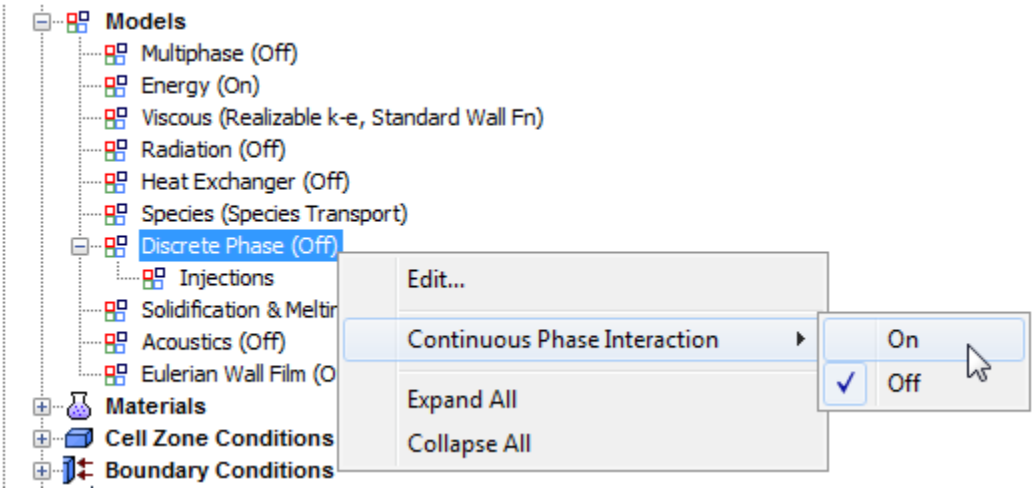
The procedure for setting up and solving a problem involving a discrete phase is outlined below, and described in detail in Options for Interaction with the Continuous Phase (p. 1241) – Postprocessing for the Discrete Phase (p. 1329). Only the steps related specifically to discrete phase modeling are shown here. For information about inputs related to other models that you are using in conjunction with the discrete phase models, see the appropriate sections for those models.

1. Enable any of the discrete phase modeling options, if relevant, as described in Options for Interaction with the Continuous Phase (p. 1241).
2. Choose a transient or steady treatment of particles as described in Steady/Transient Treatment of Particles (p. 1242).
3. Specify tracking parameters as described in Tracking Parameters for the Discrete Phase Model (p. 1246).
4. Enable the required physical submodels for the discrete phase model, as described in Physical Models for the Discrete Phase Model (p. 1249).
5. Set the numerics parameters and solve the problem, as described in Numerics of the Discrete Phase Model (p. 1260) and Solution Strategies for the Discrete Phase (p. 1325).
6. Specify the injection-specific models, initial conditions, and particle size distributions as described in Setting Initial Conditions for the Discrete Phase (p. 1265).
7. Define the boundary conditions, as described in Setting Boundary Conditions for the Discrete Phase (p. 1301).
8. Define the material properties, as described in Setting Material Properties for the Discrete Phase (p. 1313).
9. Initialize the flow field.
10. Solve the coupled or uncoupled flow (Solution Strategies for the Discrete Phase (p. 1325)).
11. For transient cases, advance the solution in time by taking the desired number of time steps. Particle positions will be updated as the solution advances in time. If you are solving an uncoupled flow, the particle position will be updated at the end of each time step. For a coupled calculation, the positions are iterated on or within each time step.
12. Examine the results, as described in Postprocessing for the Discrete Phase (p. 1329).

23.2.1. Options for Interaction with the Continuous Phase

If the discrete phase interacts (that is, exchanges mass, momentum, and/or energy) with the continuous phase, you should enable **Interaction with Continuous Phase**.

Setup → Models → Discrete Phase → Continuous Phase Interaction → On



An input for the **DPM Iteration Interval** will appear, which allows you to control the frequency at which the particles are tracked and the DPM sources are updated.

For steady-state simulations, increasing the **DPM Iteration Interval** will increase stability but require more iterations to converge.

In addition, another option exists that allows you to control the numerical treatment of the source terms and how they are applied to the continuous phase equations. For unsteady simulations, **Update DPM Sources Every Flow Iteration** is the default (and recommended) option; at every DPM Iteration, the particle source terms are recalculated. The source terms applied to the continuous phase equations transition to the new values every flow iteration based on Equation 16.440 to Equation 16.442 in the Theory Guide. This process is controlled by the under-relaxation factor, specified in the **Solution Controls** task page, see Under-Relaxation of the Interphase Exchange Terms (p. 1328).

23.2.2. Steady/Transient Treatment of Particles

The Discrete Phase Model uses a Lagrangian approach to derive the equations for the underlying physics, which are solved transiently. Transient numerical procedures in the Discrete Phase Model can be applied to resolve steady flow simulations as well as transient flows.

In the Discrete Phase Model Dialog Box (p. 2278) you have the option of choosing whether you want to treat the particles in an unsteady or a steady fashion. This option can be chosen independent of the settings for the solver. Thus, you can perform steady-state trajectory simulations even when selecting a transient solver for numerical reasons. You can also specify unsteady particle tracking when solving the steady continuous phase equations. This can be used to improve numerical stability for very large particle source terms or simply for postprocessing purposes. Whenever you enable a breakup or collision model to simulate sprays, the **Unsteady Particle Tracking** will be switched on automatically.

When **Unsteady Particle Tracking** is enabled, several new options appear. If steady-state equations are solved for the continuous phase, you simply enter the **Particle Time Step Size** and the **Number of Time Steps**, thus tracking particles every time a DPM iteration is conducted. When you increase the **Number of Time Steps**, the droplets penetrate the domain faster.

When solving unsteady equations for the continuous phase, you must decide whether you want to use **Fluid Flow Time Step** to inject the particles, or you prefer a **Particle Time Step Size** independent of the **Fluid Flow Time Step**. With the latter option, you can use the Discrete Phase Model in combination with changes in the time step for the continuous equations, as it is done when using adaptive flow time stepping.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you do not use **Fluid Flow Time Step**, you must decide when to inject the particles for a new time step. You can either **Inject Particles at Particle Time Step** or at the **Fluid Flow Time Step**. In any case, the particles will always be tracked in such a way that they coincide with the flow time of the continuous flow solver, as long as the maximum number of time steps used to compute a single trajectory is sufficient (see Tracking Parameters for the Discrete Phase Model (p. 1246) for details).

You can use a user-defined function (`DEFINE_DPM_TIMESTEP`) to change the time step for DPM particle tracking. The time step can be prescribed for special applications where a certain time step is needed. For more information about changing the time step size for DPM particle tracking, see `DEFINE_DPM_TIMESTEP` in the Fluent Customization Manual.

Important

When the density-based solver is used with the explicit unsteady formulation, the particles are advanced once per time step and are calculated at the start of the time step (before the flow is updated).

Additional inputs are required for each injection in the Set Injection Properties Dialog Box (p. 2796), as detailed in Defining Injection Properties (p. 1286). For **Unsteady Particle Tracking**, the injection **Start Time** and **Stop Time** must be specified under **Point Properties**. Injections with start and stop times set to zero will be injected only at the start of the calculation ($t=0$). If the In-Cylinder mesh motion is enabled, the start and stop times are replaced by **Start Crank Angle** and **Stop Crank Angle**, respectively. The injection specified in this way will be repeated at the starting and stopping crank angle if the simulation is run through more than one cycle. Changing injection settings during a transient simulation will not affect particles currently released in the domain. At any point during a simulation, you can clear particles that are currently in the domain by clicking the **Clear Particles** button in the Discrete Phase Model Dialog Box (p. 2278).

You can choose the **Parcel Release Method** to determine how ANSYS Fluent creates parcels. For an overview of the concept of parcels, see Parcels (p. 1237). The methods available are:

standard

injects a single parcel per injection stream per time step. The number of particles in the parcel, NP, is determined as follows:

$$NP=\dot{m}_s\frac{\Delta t}{m_p} \tag{23.1}$$

where,

NP is the number of particles in a parcel

$\dot{m}_s$ is the mass flow rate of the particle stream

Δt is the time step

m_p is the particle mass

This is the default method.

constant-number

injects parcels with a user-specified number of particles per parcel. The number of parcels is determined to satisfy the specified mass-flow rate and particle size distribution for the injection.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

constant-mass
injects parcels with a user-specified parcel mass. The number of parcels is determined to satisfy the specified mass-flow rate and particle size distribution for the injection.

constant-diameter
injects parcels with a user-specified parcel diameter. The number of parcels is determined to satisfy the specified mass-flow rate and particle size distribution for the injection.

Note that for atomizer injections, **file** injections, or injections that use the `DEFINE_DPM_INJECTION_INIT` user defined function, the Fluent solver automatically uses the default standard parcel release method. Other parcel release methods are not available.

For cases involving sprays and particle size distributions in general, the recommended setting for **Parcel Release Method** is **constant-number**. For DEM simulations, you can use **constant-diameter** or **constant-mass** to ensure that the parcel diameter does not exceed the size of the smallest cells in the computational mesh.

Note that a lower value specified for **constant-number**, **constant-mass**, or **constant-diameter** will result in a larger number of parcels injected and a finer discretization of the DPM phase. This may be beneficial for accuracy and stability of the calculation, at the expense of additional computational cost.

The **Parcel Release Method** is specified in the **Parcel** tab of the **Set Injection Properties** dialog box.

You can also choose one of several methods to control when the particles are advanced.

- If the **DPM Iteration Interval** is less than the number of iterations specified to converge the continuous phase between time steps, then sub-iterations are done. Here, particles are tracked to their new positions during a time step and DPM sources are updated; particles are then returned to their original state at the beginning of the time step. At the end of the time step, particles are advanced to their new positions based on the continuous-phase solution.
- If the **DPM Iteration Interval** is larger than the number of iterations specified to converge the continuous phase between time steps, the particles are advanced at the beginning of the time step to compute the particle source terms.
- If you specify a value of zero as the **DPM Iteration Interval**, the particles are advanced at the end of the time step. Note that if you have previously enabled the resetting of DPM source terms at the beginning of every time step using the TUI command `define/models/dpm/interaction/reset-sources-at-timestep?`, ANSYS Fluent will disable this option once you set the **DPM Iteration Interval** to zero, because this feature combination is not advisable.

In all the above cases, you must provide a sufficient number of particle source term updates to better control when the particles are advanced, see Figure 23.36: Effect of Number of Source Term Updates on Source Term Applied to Flow Equations (p. 1329).

Important

- In steady-state discrete phase modeling, particles do not interact with each other and are tracked one at a time in the domain.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If the collision model is used, you will not be able to set the **DPM Iteration Interval**. Refer to Collision and Droplet Coalescence Model Theory in the *Fluent Theory Guide* for details about this limitation.

Note

As explained in Setting Initial Conditions for the Discrete Phase (p. 1265), the injection flow rate is defined per unit meter of depth in 2D problems. In such cases, each injected parcel is considered to be a solid cylinder of diameter d_{2D} and depth 1 meter. The parcel volume is then expressed as:

$$V_{2D}=\frac{\pi}{4}{d_{2D}}^2\cdot 1\,m$$

However, the particles that are dense-packed in the parcel are assumed to be spheres rather than pucks (ice-hockey). The volume of each particle is the same as in 3D cases:

$$V_p=\frac{\pi}{6}{d_p}^3$$

Consider next the theoretical atomic packing factor β of spherical particles in a cylinder of one meter depth, also expressed as the volume ratio of all particles to all injected parcels.

In 2D, the particles of diameter d_p are stacked on top of one another in a cylinder of diameter d_p and depth 1 meter. The total number of particles that can be stacked in the cylinder in such a way is $1\,\mathrm{m}/d_p$. The total volume occupied by these particles is

$$V_1=\frac{\pi}{6}{d_p}^3\cdot 1\,\mathrm{m}/d_p$$

The volume of the surrounding parcel cylinder of depth 1 m is

$$V_2=\frac{\pi}{4}{d_p}^2\cdot\ 1\,\mathrm{m}$$

The atomic packing factor β will have a constant value of 2/3 when expressed as:

$$\beta=V_1/V_2=\left(\frac{\pi}{6}{d_p}^3\cdot 1\,\mathrm{m}/d_p\right)\Big/\left(\frac{\pi}{4}{d_p}^2\cdot\ 1\,\mathrm{m}\right)=\frac{2}{3}$$

In order to use the same parameters (spring constant k and coefficient of restitution η) for the DEM spring dashpot models in both 3D and 2D simulations, parcels of the same mass must be injected in 3D and 2D.

In 3D, the injected parcel is a sphere with diameter d_{3D} and mass $m_{3D}=\rho_p\cdot\frac{\pi}{6}{d_{3D}}^3$. The number of spherical particles in a spherical parcel is calculated by

$$NP=m_{3D}/m_p=\rho_p\cdot\frac{\pi}{6}{d_{3D}}^3\Big/\rho_p\cdot\frac{\pi}{6}{d_p}^3$$

In 2D, the parcel is a cylinder of 1 m depth. This cylinder has the same mass as the spherical parcel in 3D ($m_{2D}=m_{3D}$), but its volume differs and is calculated as:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$V_{prcl,2D}=\frac{\pi}{4}{d_{2D}}^2\cdot\ 1\,\mathrm{m}$$

The number of particles per cylindrical parcel NP and the volume they occupy is the same as in 3D, that is

$$V_{p,2D}=V_{p,3D}=NP\ \frac{\pi}{6}{d_p}^3$$

Since the ratio of these two volumes must be equal to the theoretical atomic packing factor β, we obtain

$$\left(NP\cdot\ \frac{\pi}{6}{d_p}^3\right)\Big/\left(\frac{\pi}{4}{d_{2D}}^2\cdot\ 1m\right)=\ \beta=\frac{2}{3}$$

The parcel diameter in 2D can then be calculated as:

$$d_{2D}=\sqrt{NP\cdot\ {d_p}^3/1\,\mathrm{m}}=\sqrt{{d_{3D}}^3/1\,\mathrm{m}}$$

Note that in 2D, the parcel diameter d_{2D} is used as a collision range and it is different than the parcel diameter d_{3D} in 3D.

For each parcel release method, the input values for the parcel mass and parcel diameter (m_{3D} and d_{3D}, respectively) are the same in both 3D and 2D, while the output values for parcel diameters are different: d_{2D} in 2D simulations and d_{3D} in 3D simulations.

23.2.3. Tracking Parameters for the Discrete Phase Model

You will use two parameters to control the time integration of the particle trajectory equations:

- the maximum number of time steps

  This factor is used to abort trajectory calculations when the particle never exits the flow domain.

- the length scale/step length factor

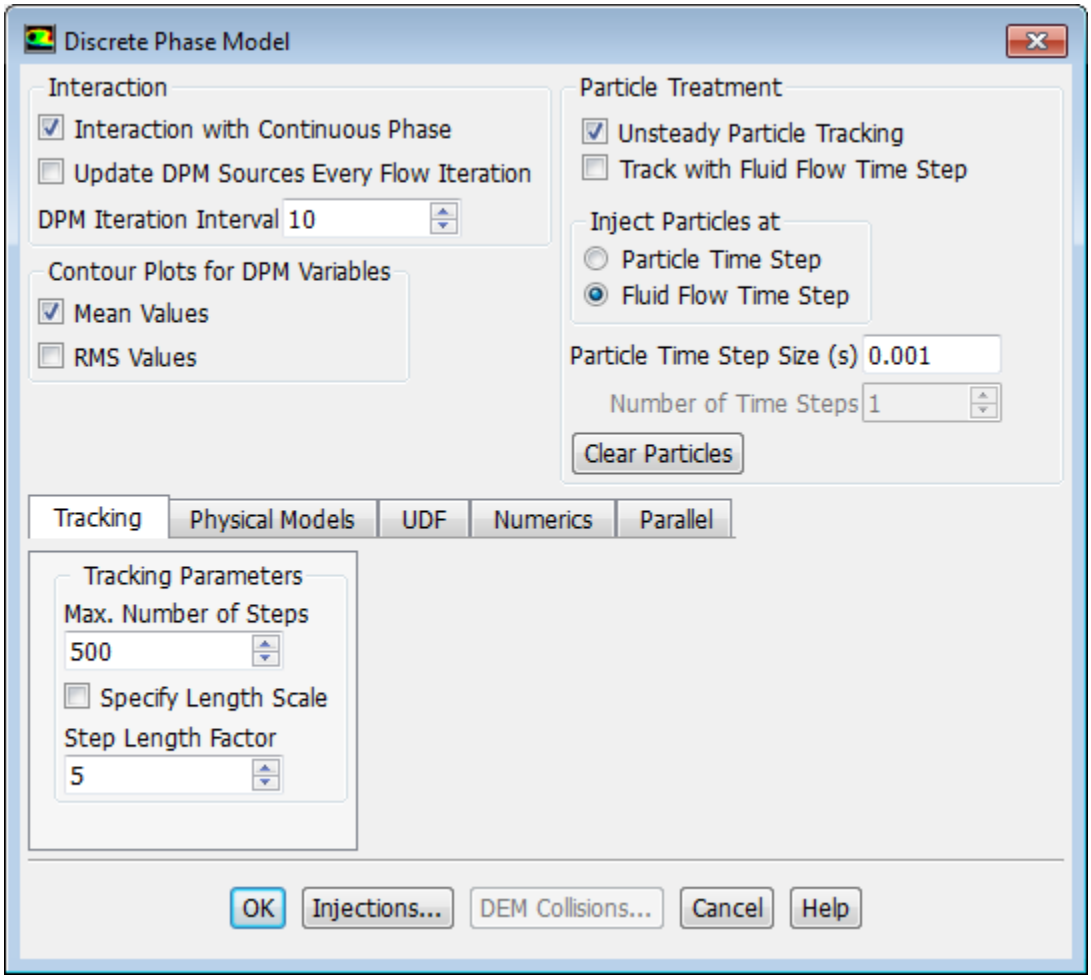
  This factor is used to set the time step for integration within each control volume.

Each of these parameters is set in the Discrete Phase Model Dialog Box (p. 2278) (Figure 23.1: The Discrete Phase Model Dialog Box and the Tracking Parameters (p. 1247)) under **Tracking Parameters** in the **Tracking** tab.

Setup → **Models** → **Discrete Phase** → **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.1: The Discrete Phase Model Dialog Box and the Tracking Parameters



Max. Number of Steps

is the maximum number of time steps used to compute a single particle trajectory via integration of Equation 16.1 in the Theory Guide. When the maximum number of steps is exceeded, ANSYS Fluent abandons the trajectory calculation for the current particle injection and reports the trajectory fate as "incomplete". The limit on the number of integration time steps eliminates the possibility of a particle being caught in a recirculating region of the continuous phase flow field and being tracked infinitely. The default value for this parameter is 50,000 for steady-state particle tracking and 500 for unsteady particle tracking. Note that you may easily create problems in which the default value is insufficient for completion of the trajectory calculation. In this case, when trajectories are reported as incomplete within the domain and the particles are not recirculating indefinitely, you can increase the maximum number of steps (up to a limit of 10^9).

Note

If, when opening a previous simulation with unsteady DPM particle tracking, you receive a warning reporting that a fraction of the discrete phase mass is "behind in time", you can use the reported percentage values to determine if it is a significant enough discrepancy to warrant revising the simulation to have a higher value for **Max. Number of Steps**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Length Scale

controls the integration time step size used to integrate the equations of motion for the particle. The integration time step is computed by ANSYS Fluent based on a specified length scale L, and the velocity of the particle (u_p) and of the continuous phase (u_c):

$$\Delta t = \frac{L}{u_p + u_c} \tag{23.2}$$

where L is the **Length Scale** that you define. As defined by Equation 23.2 (p. 1248), L is proportional to the integration time step and is equivalent to the distance that the particle will travel before its motion equations are solved again and its trajectory is updated. A smaller value for the **Length Scale** increases the accuracy of the trajectory and heat/mass transfer calculations for the discrete phase.

(Note that particle positions are always computed when particles enter/leave a cell; even if you specify a very large length scale, the time step used for integration will be such that the cell is traversed in one step.)

Length Scale will appear in the **Discrete Phase Model** dialog box when the **Specify Length Scale** option is enabled.

Step Length Factor

also controls the time step size used to integrate the equations of motion for the particle. It differs from the **Length Scale** in that it allows ANSYS Fluent to compute the time step in terms of the number of time steps required for a particle to traverse a computational cell. To set this parameter instead of the **Length Scale**, turn off the **Specify Length Scale** option.

The integration time step is computed by ANSYS Fluent based on a characteristic time that is related to an estimate of the time required for the particle to traverse the current continuous phase control volume. If this estimated transit time is defined as Δt^*, ANSYS Fluent chooses a time step Δt as

$$\Delta t = \frac{\Delta t^*}{\lambda} \tag{23.3}$$

where λ is the **Step Length Factor**. As defined by Equation 23.3 (p. 1248), λ is inversely proportional to the integration time step and is roughly equivalent to the number of time steps required to traverse the current continuous phase control volume. A larger value for the **Step Length Factor** decreases the discrete phase integration time step. The default value for the **Step Length Factor** is 5. **Step Length Factor** will appear in the **Discrete Phase Model** dialog box when the **Specify Length Scale** option is off (the default setting).

For steady-state particle tracking, one simple general rule to follow when setting the parameters above is that if you want the particles to advance through a domain consisting of N mesh cells into the main flow direction, the **Step Length Factor** times N should be approximately equal to the **Max. Number of Steps**.

When **Accuracy Control** is enabled in the **Numerics** tab, the settings for **Step Length Factor** and **Length Scale** will be used only to estimate the time step of the first integration step. In all subsequent integration steps, the particle integration time step is adapted to achieve the tolerance specified in Numerics of the Discrete Phase Model (p. 1260).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.2.4. Drag Laws

There are eight drag laws for the particles that can be selected for each injection. These are specified on the **Physical Models** tab of the **Set Injection Properties** dialog box. See Specifying Injection-Specific Physical Models (p. 1290) for details.

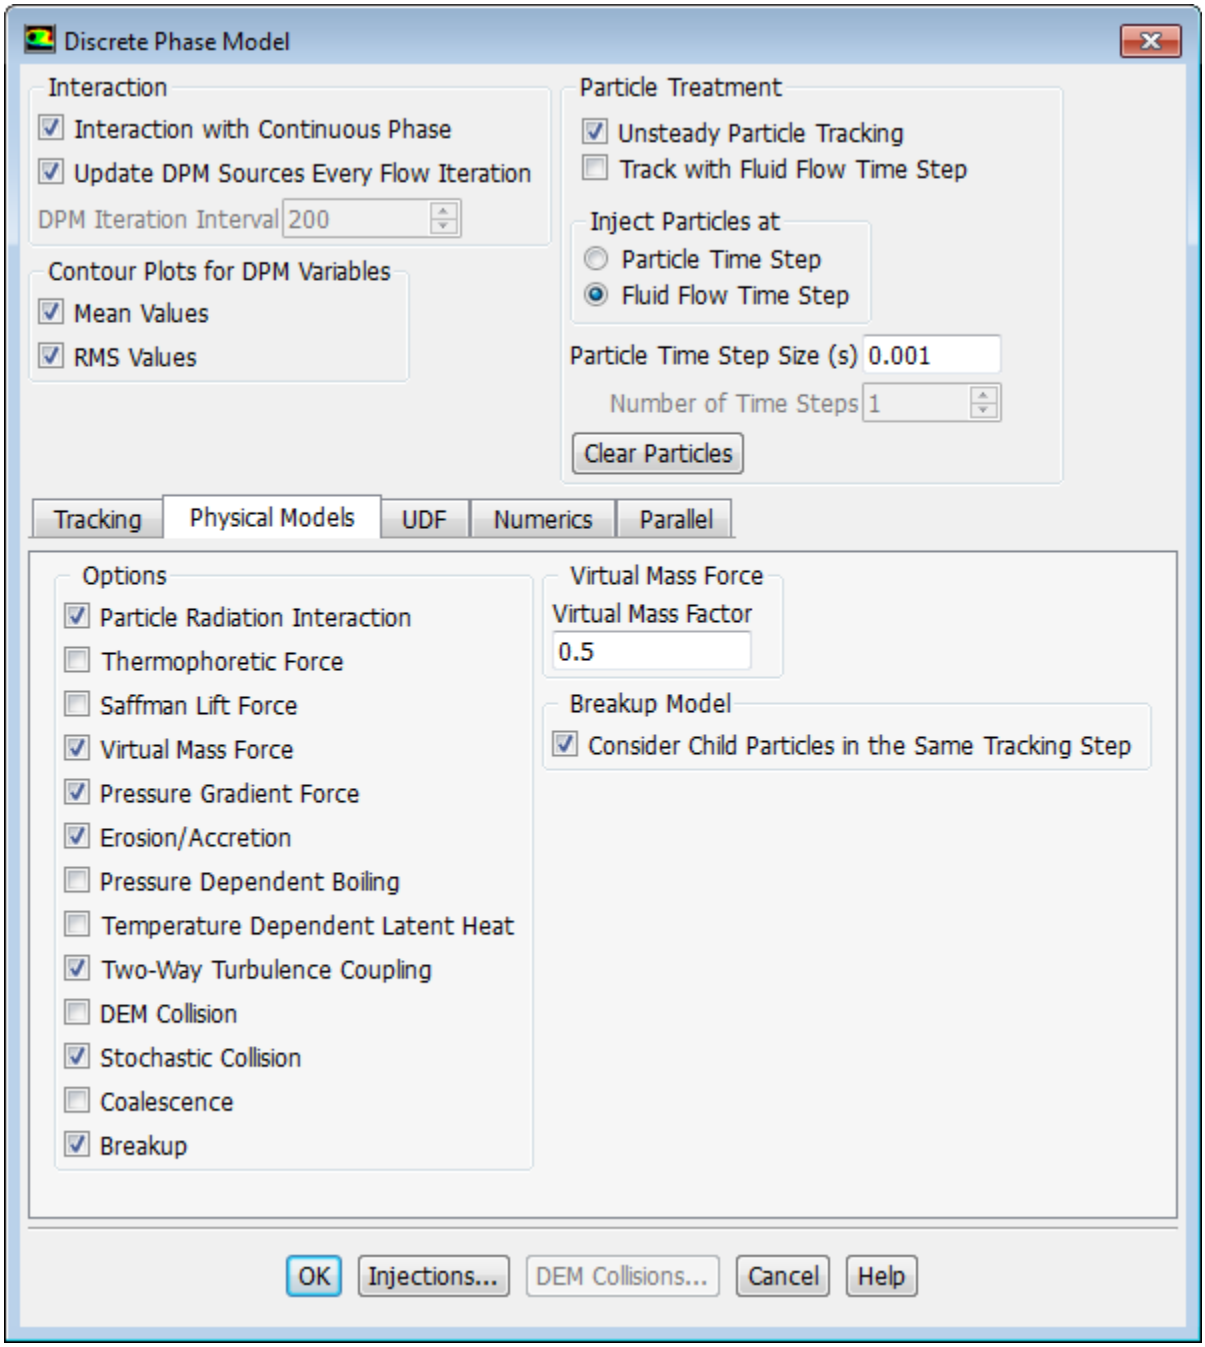
23.2.5. Physical Models for the Discrete Phase Model

This section provides instructions for using the optional discrete phase models available in ANSYS Fluent. All of them can be enabled in the **Physical Models** tab of the **Discrete Phase Model** dialog box (Figure 23.2: The Discrete Phase Model Dialog Box and the Physical Models (p. 1250)).

Setup → **Models** → **Discrete Phase** **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.2: The Discrete Phase Model Dialog Box and the Physical Models



23.2.5.1. Including Radiation Heat Transfer Effects on the Particles

If you want to include the effect of radiation heat transfer to the particles (Equation 5.34 in the Theory Guide), you must enable the **Particle Radiation Interaction** option under the **Physical Models** tab, in the Discrete Phase Model Dialog Box (p. 2278) (Figure 23.2: The Discrete Phase Model Dialog Box and the Physical Models (p. 1250)). You also must define additional properties for the particle materials (emissivity and scattering factor), as described in Description of the Properties (p. 1317). This option is available only when the P-1 or discrete ordinates radiation model is used.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.2.5.2. Including Thermophoretic Force Effects on the Particles

If you want to include the effect of the thermophoretic force on the particle trajectories (Equation 16.11 in the Theory Guide), enable the **Thermophoretic Force** option under the **Physical Models** tab, in the Discrete Phase Model Dialog Box (p. 2278). You also must define the thermophoretic coefficient for the particle material, as described in Description of the Properties (p. 1317).

23.2.5.3. Including Saffman Lift Force Effects on the Particles

For sub-micron particles, you can also model the lift due to shear (the Saffman lift force, described in Saffman's Lift Force in the Theory Guide) in the particle trajectory. To do this, enable the **Saffman Lift Force** option under the **Physical Models** tab, in the Discrete Phase Model Dialog Box (p. 2278).

23.2.5.4. Including the Virtual Mass Force and Pressure Gradient Effects on Particles

In cases where the density of the fluid approaches or exceeds the density of the particles (for example liquid flow with gaseous bubbles), it is recommended that you include the Virtual Mass and Pressure Gradient forces in the particle force balance. To do this, enable **Virtual Mass Force** and **Pressure Gradient Force** under the **Physical Models** tab in the Discrete Phase Model Dialog Box (p. 2278). See Other Forces in Fluent Theory Guide for information on the Virtual Mass and Pressure Gradient forces.

23.2.5.5. Monitoring Erosion/Accretion of Particles at Walls

To monitor particle erosion and accretion rates at wall boundaries:

1. Enable **Erosion/Accretion** in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278).

   Enabling the **Erosion/Accretion** option will cause the erosion and accretion rates to be calculated at wall boundary faces when particle tracks are updated.

2. For each wall zone, select erosion models and specify erosion model parameters as described in Setting Particle Erosion and Accretion Parameters (p. 1309).

23.2.5.6. Enabling Pressure Dependent Boiling

With this option you can modify the condition for switching from droplet vaporization (Law 2) to boiling (Law 3). By default ANSYS Fluent will switch from the vaporization to the boiling law when the particle temperature has reached the boiling point defined for the droplet material (Equation 16.118 in the Theory Guide). When the **Pressure Dependent Boiling** option is enabled, the switching condition will change to $P_{sat}>P$, where P_{sat} is the saturation vapor pressure at the droplet temperature and P is the domain pressure. If $P_{sat}<P$ while in the boiling law, the model will switch back to the vaporization law. If this option is enabled it is essential to enter the appropriate droplet saturation vapor pressure data to cover the complete pressure/temperature range in your model.

When **Pressure Dependent Boiling** is enabled, then the **Temperature Dependent Latent Heat** model automatically applies (see Including the Effect of Droplet Temperature on Latent Heat (p. 1252)).

Setting the **Pressure Dependent Boiling** option has no effect on the multicomponent particles, where switching from the vaporization to the boiling regime is always based on the component saturation vapor pressures (see Multicomponent Particle Definition (Law 7) in the Theory Guide) Finally, selection of the **Pressure Dependent Boiling** option is not available with the real-gas models, as the pressure dependence always applies. See Using the Cubic Equation of State Models with the Lagrangian Dispersed Phase Models (p. 548) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For pressures higher than the critical pressure of the droplet material ($P>P_c$), a boiling point T_b, defined as the temperature at the saturation vapor pressure ($P=P_{sat}$), cannot be determined as the vapor pressure curve is defined only up to the critical point. Under supercritical pressure conditions ($P>P_c$), the vaporization models are applicable at droplet temperatures below the critical point ($T<T_c$), and the switching condition from vaporization to boiling is never met. For supercritical pressure conditions, you must enter the droplet saturation vapor pressure data for the complete pressure/temperature range up to the critical point T_c.

When **Pressure Dependent Boiling** is enabled, you can use the text user interface command

```
/define/models/dpm/options/allow-supercritical-pressure-vaporization?
```

to enforce the switching from vaporization to boiling even if the boiling point T_b is not calculated from the vapor pressure data.

If the pressure in your model is above critical ($P>P_c$), you must retain the default setting (`yes`) for `allow-supercritical-pressure-vaporization?`.

For subcritical pressure conditions ($P<P_c$), the setting for `allow-supercritical-pressure-vaporization?` will have no effect unless the boiling point calculation fails, which usually indicates that either the vapor pressure data do not cover the complete temperature/pressure range for your model, or inaccurate data have been entered. In that case, if `allow-supercritical-pressure-vaporization?` is set to `no`, the normal boiling point T_b defined for the droplet material will be imposed as a switching condition from vaporization to boiling.

23.2.5.7. Including the Effect of Droplet Temperature on Latent Heat

To include the droplet temperature effects on the latent heat as described in Equation 16.111 in the Theory Guide, enable **Temperature Dependent Latent Heat** under the **Physical Models** tab. If you enable this option you must provide accurate temperature-dependent specific heat data for both the droplet and the evaporating species materials.

23.2.5.8. Including the Effect of Particles on Turbulent Quantities

Particles can damp or produce turbulent eddies [76] (p. 2891). In ANSYS Fluent, the formulation described in [29] (p. 2888) and [6] (p. 2887) is used to compute turbulence modulation. Damping occurs when the particle diameter is less than one tenth of the turbulent length scale. For larger particle diameters turbulence kinetic energy is produced [37] (p. 2888).

If you want to consider these effects in the chosen turbulence model, you can enable this using **Two-Way Turbulence Coupling**, under the **Physical Models** tab.

23.2.5.9. Including Collision and Droplet Coalescence

To include the effect of collisions, as described in Collision and Droplet Coalescence Model Theory in the Theory Guide, select **Stochastic Collision** and **Coalescence** under **Options**.

Note

Coalescence will appear under **Options** after **Stochastic Collision** has been enabled.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.2.5.10. Including the DEM Collision Model

The DEM collision model is suitable for simulating granular matter, where such simulations are characterized by a high volume fraction of particles, and the particle-particle interaction is important. See Modeling Collision Using the DEM Model (p. 1253) for details about using this model.

23.2.5.11. Including Droplet Breakup

To model droplet breakup in ANSYS Fluent, enable **Breakup** under **Options**. By default, this will enable breakup for all suitable injections. You can then specify the breakup models and parameters (or disable breakup) for each individual injection on the **Physical Models** tab in the **Set Injection Properties** dialog box as described in Breakup (p. 1292).

When **Breakup** is enabled, you can collect new generated child droplets and track them within the same time step by enabling **Consider Child Particles in the Same Tracking Step**. This option provides higher accuracy and can lead to faster convergence within a transient flow time step.

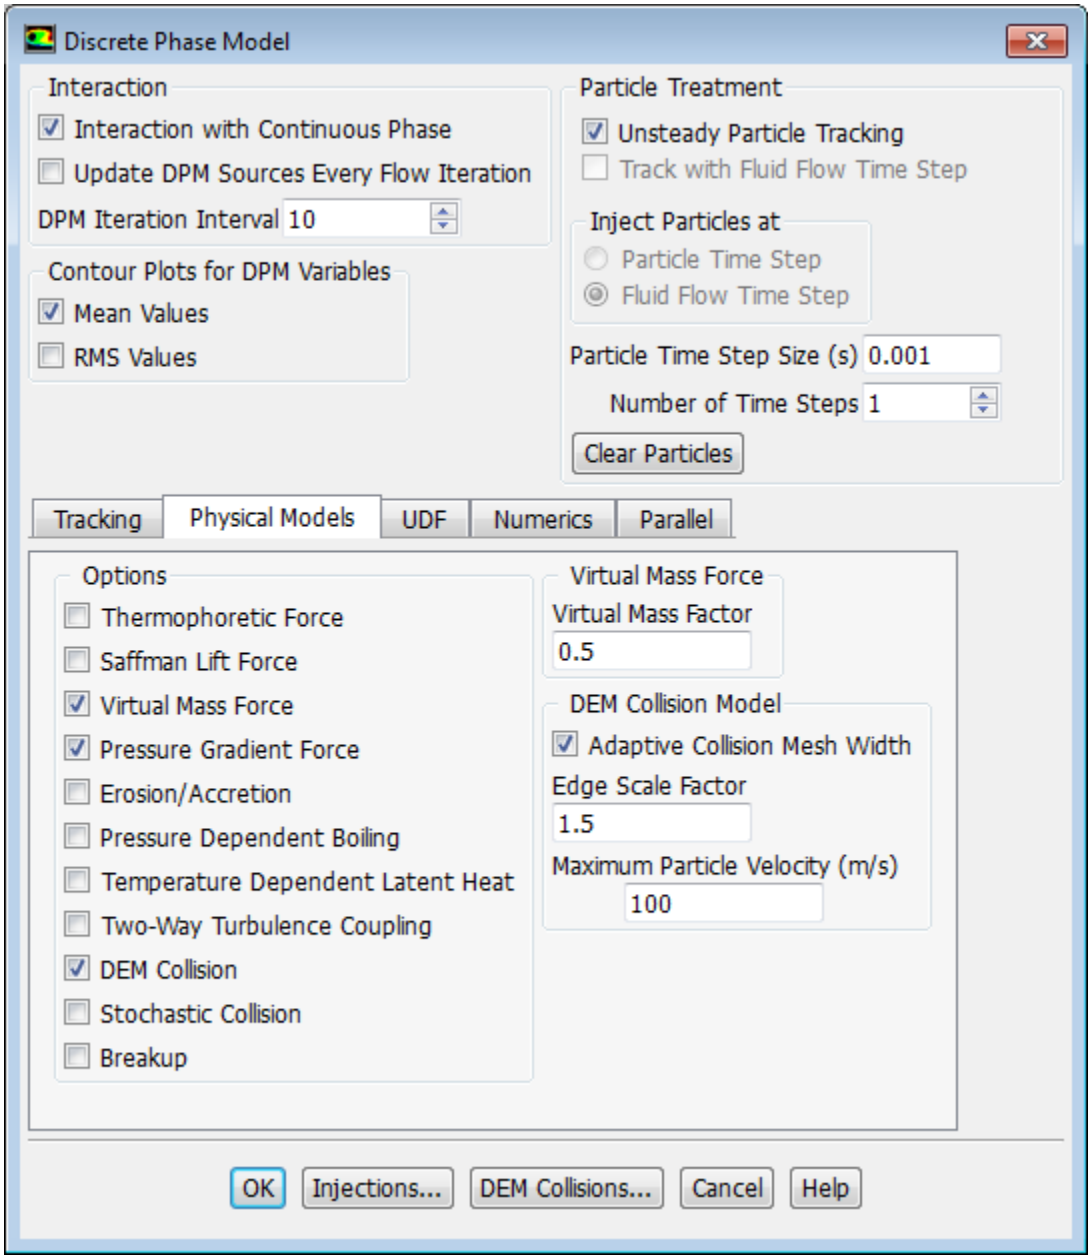
23.2.5.12. Modeling Collision Using the DEM Model

To enable the DEM collision model, select **DEM Collision** under **Options**. A detailed description of this model can be found in Discrete Element Method Collision Model in the Theory Guide.

1. In the **Physical Models** tab of the **Discrete Phase Model** dialog box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.3: Discrete Phase Dialog Box with DEM Collision Model



a. Specify the settings your model requires under **DEM Collision Model**.

b. (Optional) By default, **Adaptive Collision Mesh Width** is enabled. This adjusts the width of the collision mesh to the largest parcel diameter multiplied by the **Edge Scale Factor**. If **Adaptive Collision Mesh Width** is disabled, a fixed **Static Collision Mesh Width** has to be given in the chosen units of length.

c. The **Maximum Particle Velocity** limits the maximum particle velocity to a physically plausible range.

2. Set up the injection.

Setup → Models → Discrete Phase → Injections New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

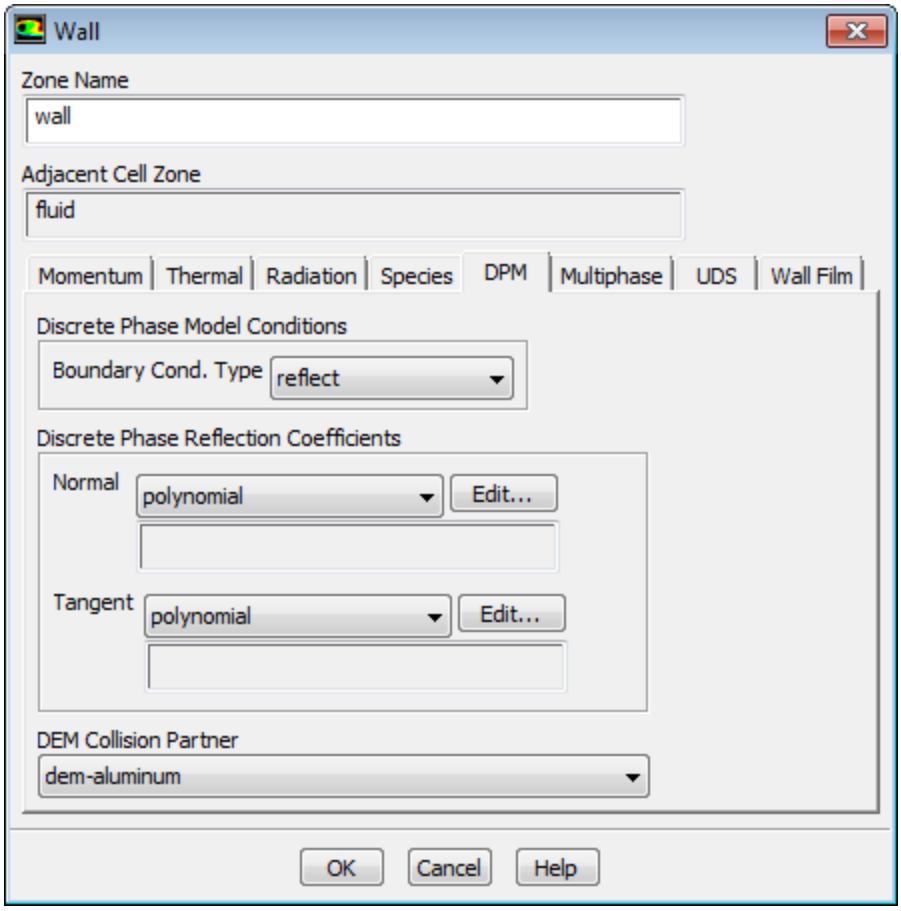
a. In the **Set Injection Properties** dialog box, select a name from the **DEM Collision Partner** drop-down list that will serve as the collision partner. A default name using the particle material will be suggested.

> **Note**
>
> Selecting none from the drop-down list indicates that the particles released from this injection do not participate in the DEM collision computation.

b. If you want to use the rolling friction collision law (see step 4), under the **Physical Models** tab, enable **Particle Rotation** for those injections whose particles take part in collisions with rolling friction.

3. Set the boundary conditions for the discrete phase as you normally would. If the **Boundary Cond. Type** is **reflect**, select a name from the **DEM Collision Partner** drop-down list to designate the collision partner For example, in Figure 23.4: Wall Boundary Condition for the DEM Model (p. 1255), a wall boundary condition will suggest a wall material name, which will designate the collision partner. The name will have a **dem-** prefix However, if the **DEM Collision Partner** is **none**, the wall will reflect particles like any other DPM particles using the settings for the **Discrete Phase Reflection Coefficients** in the **Normal** and **Tangent** directions. These settings generally apply for particles that are not colliding according to DEM, such as massless particles.

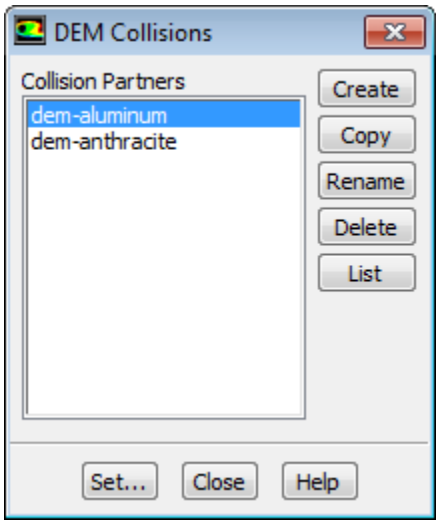
Figure 23.4: Wall Boundary Condition for the DEM Model



4. Define the particle interaction between the pairs of the collision partners.

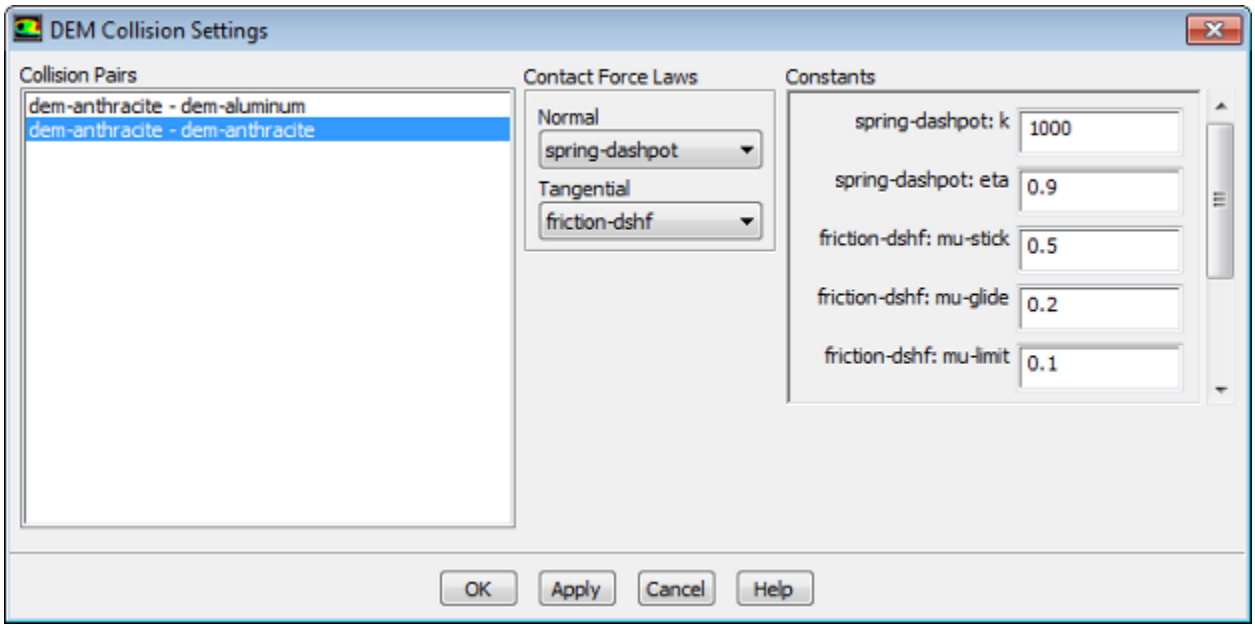
a. Click the **DEM Collisions...** button at the bottom of the **Discrete Phase Model** dialog box. The **DEM Collisions** dialog box (Figure 23.5: Collision Dialog Box (p. 1256)) will appear where you can manage the collision partners. You can **Create**, **Copy**, **Rename**, **Delete**, and **List** collision partners. To define collision laws for a collision partner, select a collision partner from the **Collision Partners** list and click the **Set...** button, or simply double-click the collision partner in the list.

Figure 23.5: Collision Dialog Box



b. In the **DEM Collision Settings** dialog box (Figure 23.6: DEM Collision Settings Dialog Box (p. 1256)), a list of all the possible **Collision Pairs** will exist.

Figure 23.6: DEM Collision Settings Dialog Box



i. Select a pair of collision partners from the **Collision Pairs** list.

ii. For this pair, select the **Contact Force Laws** that best describe the collision between these two partners.

The **Normal** contact force laws that exist are:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **spring**
- **spring-dashpot**
- **hertzian**
- **hertzian-dashpot**

You can also choose to exclude the contact force law by selecting **none**.

For the **Tangential** contact force law (if considered), you can select form the following friction collision laws:
- **friction-dshf**
- **friction-dshf-rolling** (an extension of the **friction-dshf** friction collision law including rolling friction)

Each of the laws is described in the following sections:

- The Spring Collision Law in the *Fluent Theory Guide*
- The Spring-Dashpot Collision Law in the *Fluent Theory Guide*
- The Hertzian Collision Law in the *Fluent Theory Guide*
- The Hertzian-Dashpot Collision Law in the *Fluent Theory Guide*
- The Friction Collision Law in the *Fluent Theory Guide*
- Rolling Friction Collision Law for DEM in the *Fluent Theory Guide*

iii. Enter the **Constants** for the chosen **Contact Force Laws**. Refer to Theory in the Theory Guide for guidance on how to find reasonable values of the force-law constants.

iv. Repeat for all other collision pairs.

v. Click **OK** or **Apply** to apply these settings.

Note

- The choice of collision laws does not depend on the order in the pair of collision partners.
- Failing to specify a force law for a collision pair implies that respective particles will not collide.
- Rolling friction will only be factored in for a particular DEM particle injection if the **Particle Rotation** option is selected in the **Set Injection Properties** dialog box (**Physical Properties** tab).

Note

For parallel calculations, the DEM collision model can be optimized by enabling the hybrid optimization method for DPM. This method balances the load across machines, and, within each machine, the hybrid parallel DPM method is used to make sure the load is balanced by multi-threading. For more information, see the description of the **Hybrid Optimization** option in the **Weighting** tab discussion in Partitioning (p. 2033).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.2.5.12.1. Limitations

The following limitations currently apply when using the DEM collision model:

- Axisymmetric geometry cannot be used.
- Dynamic mesh motion cannot be used.
- The Eulerian wall film model cannot be used.
- Shear stress boundary conditions cannot be used at walls.
- Marangoni stress boundary condition cannot be used at walls.
- DEM particles do not transfer heat from particle to particle during contact.

23.2.5.12.2. Numeric Recommendations

To better preserve energy during particle collision, the following settings in the **Numerics** tab are recommended and will be automatically set when DEM Collisions are enabled.

1. Disable **Accuracy Control** to ensure that DEM time stepping remains small.
2. Disable **Automated** under **Tracking Scheme Selection**.
3. Select **implicit** from the **Tracking Scheme** drop-down list.

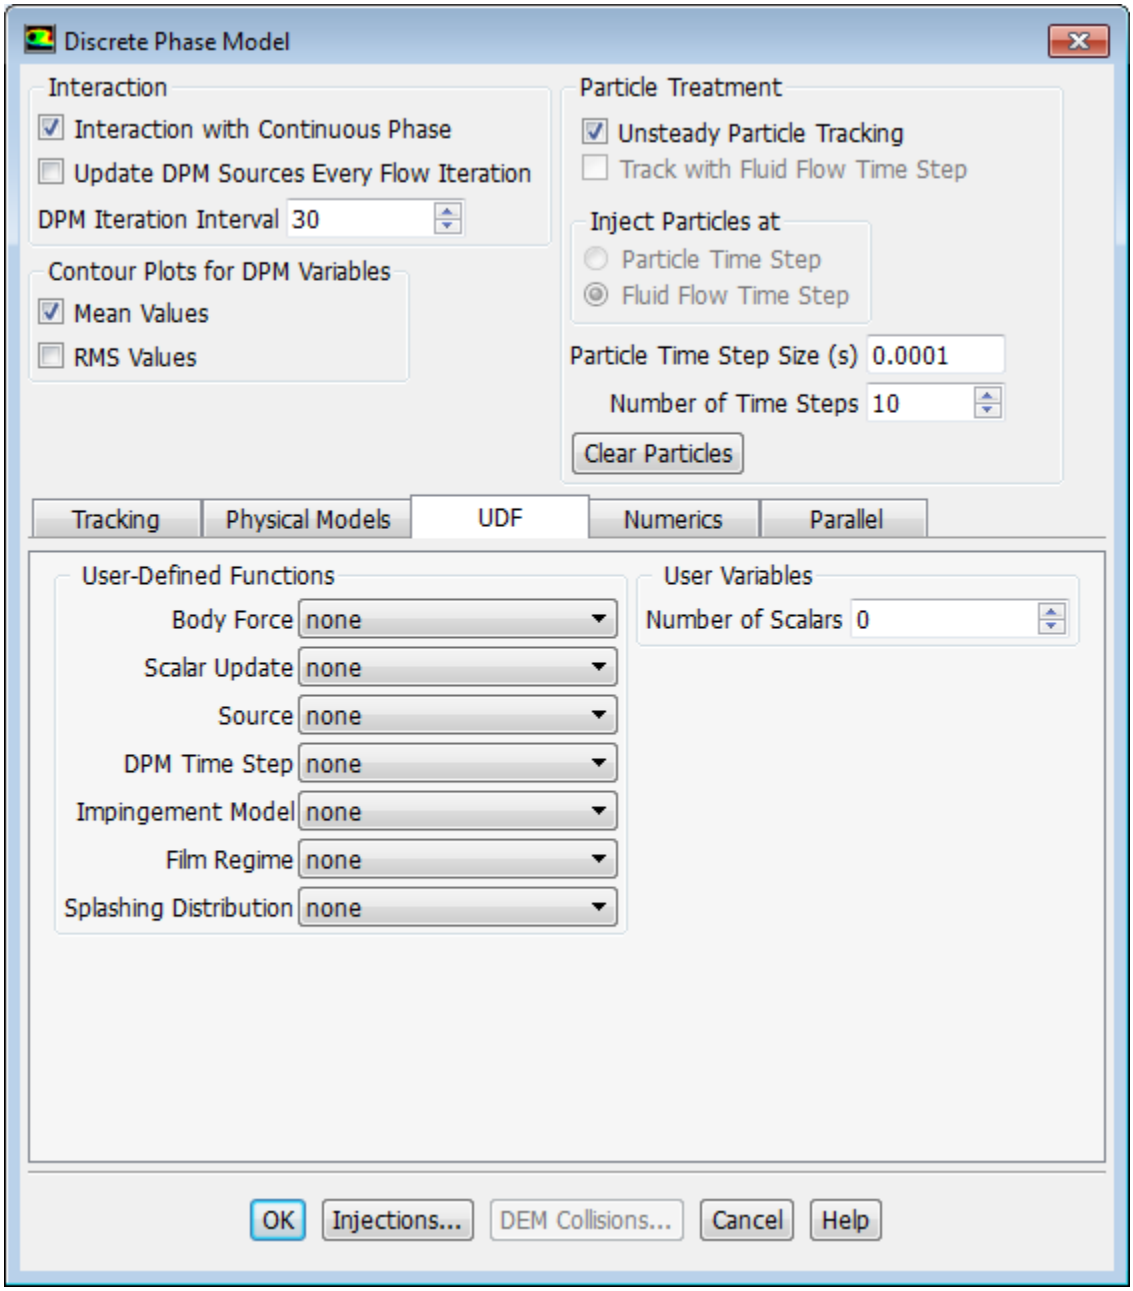
Refer to Numerics for Tracking of the Particles (p. 1261) for more information about the settings in the **Numerics** tab.

23.2.6. User-Defined Functions

User-defined functions can be used to customize the discrete phase model to include additional body forces, modify interphase exchange terms (sources), calculate or integrate scalar values along the particle trajectory, and incorporate nonstandard erosion rate definitions. More information about user-defined functions can be found in the Fluent Customization Manual.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.7: The Discrete Phase Model Dialog Box and the UDFs



In the Discrete Phase Model Dialog Box (p. 2278), under **User-Defined Functions** in the **UDF** tab, there are drop-down lists labeled **Body Force**, **Scalar Update**, **Source**, **Spray Collide Function**, and **DPM Time Step** (Figure 23.7: The Discrete Phase Model Dialog Box and the UDFs (p. 1259)). If **Erosion/Accretion** is enabled under the **Physical Models** tab, there will be an additional drop-down list labeled **Erosion/Accretion**. The **Impingement Model**, **Film Regime** and **Splashing Distribution** drop-down lists will become available if either **wall-film** is selected for **Boundary Cond. Type** in the **DPM** tab of the **Wall** dialog box or the **Eulerian Wall Film** model is enabled. Note that user-defined Impingement Model and Splashing Distribution will overwrite the impingement/splashing model selected for the Lagrangian or Eulerian wall film boundary condition.

These lists will show available user-defined functions that can be selected to customize the discrete phase model (see Fluent Customization Manual for more information).

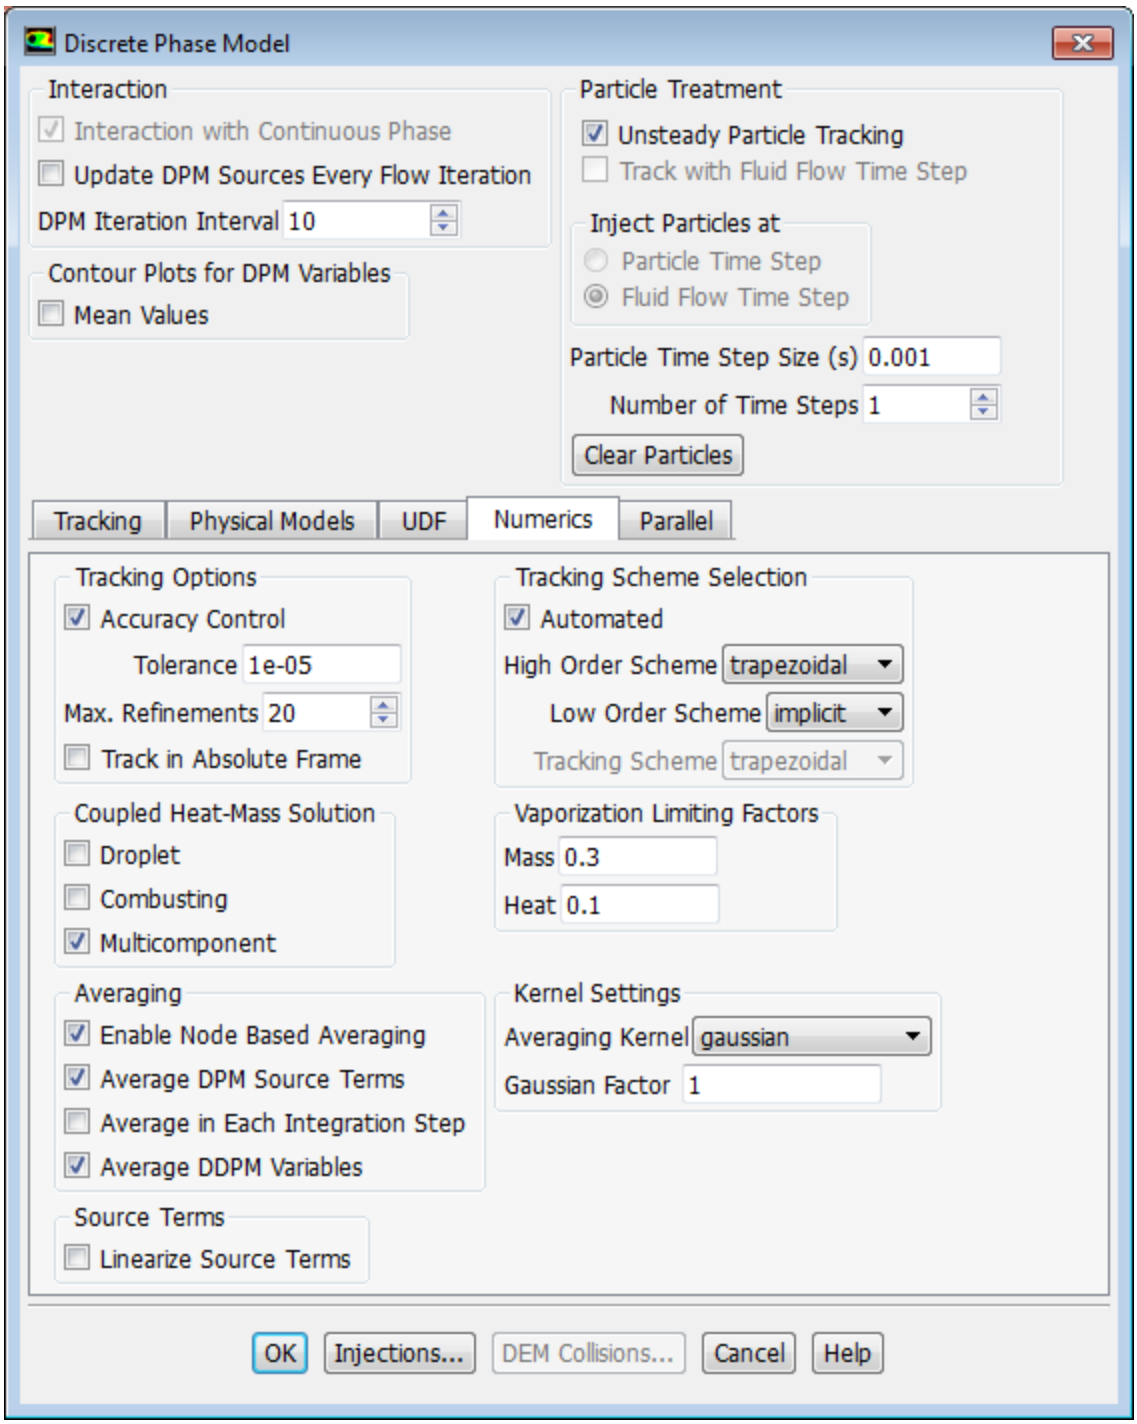
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

In addition, you can specify a **Number of Scalars** which are allocated to each particle and can be used to store information when implementing your own particle models.

23.2.7. Numerics of the Discrete Phase Model

The underlying physics of the Discrete Phase Model is described by ordinary differential equations (ODE) as opposed to the continuous flow which is expressed in the form of partial differential equations (PDE). Therefore, the Discrete Phase Model uses its own numerical mechanisms and discretization schemes, which are completely different from other numerics used in ANSYS Fluent.

Figure 23.8: The Discrete Phase Model Dialog Box and the Numerics



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Numerics** tab gives you control over the numerical schemes for particle tracking as well as solutions of heat and mass equations (Figure 23.8: The Discrete Phase Model Dialog Box and the Numerics (p. 1260)).

23.2.7.1. Numerics for Tracking of the Particles

To solve equations of motion for the particles, the following numerical schemes are available:

implicit
uses an implicit Euler integration of Equation 16.1 in the Theory Guide which is unconditionally stable for all particle relaxation times.

trapezoidal
uses a semi-implicit trapezoidal integration.

analytic
uses an analytical integration of Equation 16.1 of the Theory Guide where the forces are held constant during the integration.

runge-kutta
facilitates a 5th order Runge Kutta scheme derived by Cash and Karp [19] (p. 2887).

For additional details, see Solution Strategies for the Discrete Phase (p. 1325).

You can either choose a single tracking scheme, or switch between higher order and lower order tracking schemes using an automated selection based on the accuracy to be achieved and the stability range of each scheme. In addition, you can control how accurately the equations need to be solved.

Accuracy Control
enables the solution of equations of motion within a specified tolerance. This is done by computing the error of the integration step and reducing the integration step if the error is too large. If the error is within the given tolerance, the integration step will also be increased in the next steps.

Tolerance
is the maximum relative error that has to be achieved by the tracking procedure. Based on the numerical scheme, different methods are used to estimate the relative error. The implemented Runge-Kutta scheme uses an embedded error control mechanism. The error of the other schemes is computed by comparing the result of the integration step with the outcome of a two step procedure with half the step size.

Max. Refinements
is the maximum number of step size refinements in one single integration step. If this number is exceeded the integration will be conducted with the last refined integration step size.

Automated Tracking Scheme Selection
provides a mechanism to switch in an automated fashion between numerically stable lower order schemes and higher order schemes, which are stable only in a limited range. In situations where the particle is far from hydrodynamic equilibrium, an accurate solution can be achieved very quickly with a higher order scheme, since these schemes need less step refinements for a certain tolerance. When the particle reaches hydrodynamic equilibrium, the higher order schemes become inefficient since their step length is limited

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

to a stable range. In this case, the mechanism switches to a stable lower order scheme and facilitates larger integration steps.

Important

This mechanism is only available when **Accuracy Control** is enabled.

Higher Order Scheme
can be chosen from the group consisting of **trapezoidal** and **runge-kutta** scheme.

Lower Order Scheme
consists of **implicit** and the exponential **analytic** integration scheme.

Tracking Scheme
is selectable only if **Automated** is switched off. You can choose any of the tracking schemes. You also can combine each of the tracking schemes with **Accuracy Control**.

Note

- When **DEM Collisions** are enabled, ANSYS Fluent will automatically set **Tracking Scheme** to **implicit** and disable **Accuracy Control**.
- The equation for rotating particle motion (Equation 16.210 in the *Fluent Theory Guide*) is solved using the Euler implicit discretization scheme.

23.2.7.2. Including Coupled Heat-Mass Solution Effects on the Particles

By default, the particle heat and mass equations are solved in a segregated manner using an implicit Euler integration over the time step used for the trajectory calculation If you enable the **Coupled Heat-Mass Solution** option for the **Droplet**, **Combusting**, or **Multicomponent** particles, ANSYS Fluent will solve the corresponding equations using a coupled ODE solver with error tolerance control. The increased accuracy, however, comes at the expense of increased computational time.

To ensure solution accuracy for the **Droplet** and **Multicomponent** particles, ANSYS Fluent will automatically switch to the coupled algorithm during the integration time step when the evaporated mass is greater than the limiting mass change Δm_p (defined in Equation 23.4 (p. 1262)), or when the particle temperature change is greater than the limiting temperature change ΔT_p (defined in Equation 23.5 (p. 1262)).

$$\Delta m_p = m_p a_m \tag{23.4}$$

where m_p is the particle mass (kg) and a_m is the vaporization limiting factor for the mass.

$$\Delta T_p = min\left(\left|T_p - T_\infty\right| a_T, T_p a_T\right) \tag{23.5}$$

where T_p is the particle temperature (K), T_∞ is the bulk temperature (K), and a_T is the vaporization limiting factor for the temperature.

You will enter the **Vaporization Limiting Factors** for **Mass** a_m and **Heat** a_T. The defaults 0.3 and 0.1 are recommended.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.2.7.3. Tracking in a Reference Frame

Particle tracking is related to a coordinate system. With **Track in Absolute Frame** enabled, you can choose to track the particles in the absolute reference frame. All particle coordinates and velocities are then computed in this frame. The forces due to friction with the continuous phase are transformed to this frame automatically.

In rotating flows it might be appropriate for numerical reasons to track the particles in the relative reference frame. If several reference frames exist in one simulation, then the particle velocities are transformed to each reference frame when they enter the fluid zone associated with this reference frame.

When the impact of particles with walls in multiple rotating reference frames is important, as it is the case with a rotating impeller in a stationary baffled tank, it is necessary to model the flow as a sliding mesh simulation.

23.2.7.4. Node Based Averaging of Particle Data

In general, the presence of DPM parcels may affect the continuous phase fluid flow meaning that discrete phase source terms and particle data such as fluid drag, temperature, volume fraction, and velocity can be integrated into the flow solver. By default in ANSYS Fluent, the effects of a particular DPM parcel are applied only to the cell containing that parcel. As an alternative, **Node Based Averaging** is offered which distributes the effects of a DPM parcel among neighboring nodes in the mesh. This allows a reduction of grid dependency of DPM simulations, since each parcel's effects on the flow solver are distributed more smoothly across neighboring cells.

You can enable **Node Based Averaging** in the **Numerics** tab of the **Discrete Phase Model** dialog box, as shown in Figure 23.8: The Discrete Phase Model Dialog Box and the Numerics (p. 1260).

When enabled, **Node Based Averaging** is applied to particle velocity, particle temperature, particle volume fraction, and DPM concentration. By default, **Average DPM Source Terms** is also enabled, which applies node averaging to the source terms as well. When the Dense Discrete Phase Model is being used, the **Average DDPM Variables** option appears to provide node based averaging for the discrete phase specific variables, such as DDPM particle drag. When **Contour Plots for DPM Variables** is enabled (Reporting of Discrete Phase Variables (p. 1351)), these quantities will also be node averaged.

Average in Each Integration Step should be enabled if you find that the flux report is showing discrepancies for mass flow rates of particles injected into and leaving the domain. This option increases computation time so it is not enabled by default.

Once you have enabled **Node Based Averaging**, you must also select the **Averaging Kernel** to accumulate the particle related data on the mesh nodes and to redistribute them back to the finite volume cells. The kernel and related settings are specified in the **Kernel Settings** section of the **Discrete Phase Model** dialog box. The following kernels are available:

- **nodes-per-cell**
- **shortest-distance**
- **inverse-distance**
- **gaussian**

  If you use the **gaussian** kernel, you must also specify the **Gaussian Factor**, which determines the width of the Gaussian distribution. The default value is 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For details about the averaging and kernel equations, refer to Node Based Averaging in the Theory Guide.

23.2.7.5. Linearized Source Terms

Source terms for discrete phase momentum, energy, and species can be linearized with respect to the cell variable, ϕ:

$$S_{DPM,\phi}=S_{const}+S_{lin}\phi \tag{23.6}$$

This linearization strongly increases numerical stability for steady flows. For transient flows, it typically allows the use of larger time steps and larger under-relaxation factors for the DPM model.

You can enable source term linearization with the **Linearize Source Terms** option in the **Numerics** tab of the **Discrete Phase Model** dialog box.

The source term linearization can be combined with the **Average DPM Source Terms** (Node Based Averaging of Particle Data (p. 1263)) and **Update DPM Sources Every Flow Iteration** (Options for Interaction with the Continuous Phase (p. 1241)) options. However, you should disable **Average DPM Source Terms** when using linearized DPM source terms for vaporizing particles. Combination of these two features in vaporization cases may lead to numerical instabilities and unphysical results for the gas temperature.

23.2.7.6. Staggering of Particles in Space and Time

In order to obtain a better representation of an injector, the particles can be *staggered* spatially and/or temporally. When particles are staggered spatially, ANSYS Fluent randomly samples from the region in which the spray is specified (for example, the sheet thickness in the pressure-swirl atomizer) so that as the calculation progresses, trajectories will originate from the entire region. This allows the entire geometry specified in the atomizer to be sampled while specifying fewer streams in the input dialog box, thus decreasing computational expense.

When spatial staggering is enabled for non-atomizer injections, a stagger radius must be specified to define the region from which particles are released. The stagger radius is specified in the text user interface (TUI), using the command:

```
/define/models/dpm/options/stagger-radius
```

You can also enable injection-specific spatial staggering of the particles by selecting the **Stagger Positions** option and specifying **Stagger Radius** in the **Point Properties** tab of the **Set Injection Properties** dialog box. For more information, see the appropriate sections for injection-specific point properties.

When injecting particles in a transient calculation using relatively large time steps in relation to the spray event, the particles can clump together in discrete bunches. The clumps do not look physically realistic, though ANSYS Fluent calculates the trajectory for each particle as it passes through a cell and the coupling to the gas phase is properly accounted for. To obtain a statistically smoother representation of the spray, the particles can be staggered in time. During the first time step, the particle is tracked for a random percentage of its initial step. This results in a sample of the initial volume swept out by the particle during the first time step and a smoother, more uniform spatial distribution at longer time intervals.

The setup commands for staggering are available in the text user interface (TUI), under

- `stagger-spatially-atomizer-injections?`
- `stagger-spatially-standard-injections?`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `stagger-temporally?`
- `staggering-factor`

The "staggering factor" is applied to temporal staggering only. It is a constant that multiplies the time step size to give the random sampling interval. The staggering factor controls the percentage of every particle's initial time step that will be sampled. For example, if the staggering factor is 0.5, then the parcels in the injection will be tracked between half and all of their full initial time step. If the staggering factor is 0.1, then the parcels will be tracked between ninety percent and all of their initial time step. If the staggering factor is set to 0.9, the parcels will be tracked between ten percent and all of their initial time step. This allows you to control the amount of smoothing between injections.

The default values for the options in the TUI are spatial staggering for atomizers (including the solid-cone), no temporal staggering and a temporal staggering factor of 1.0. The temporal staggering factor is inactive until the flag for temporal staggering is enabled.

23.3. Setting Initial Conditions for the Discrete Phase

The primary inputs that you must provide for the discrete phase calculations in ANSYS Fluent are the initial conditions that define the starting positions, velocities, and other parameters for each particle stream and the physical effects acting on the particle streams, requiring additional particle properties. You will define the initial conditions for a particle/droplet stream by creating an "injection" and assigning properties to it.

The required initial conditions depend on the injection type, while the physical effects are selected by choosing an appropriate particle type. For some injection types you can provide a particle size distribution, like the Rosin-Rammler distribution, see Using the Rosin-Rammler Diameter Distribution Method (p. 1281).

The initial conditions provide the starting values for all of the dependent discrete phase variables that describe the instantaneous conditions of an individual particle, and include the following:

- position (x, y, z coordinates) of the particle
- velocities (u, v, w) of the particle

  Velocity magnitudes and spray cone angle can also be used (in 3D) to define the initial velocities (see Point Properties for Cone Injections (p. 1271)). For moving reference frames, relative velocities should be specified.

- diameter of the particle, d_p
- temperature of the particle, T_p
- mass flow rate of the particle stream that will follow the trajectory of the individual particle/droplet, $\dot{m}_p$ (required only for coupled calculations)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- additional parameters if one of the atomizer models described in Atomizer Model Theory in the Theory Guide is used for the injection

> **Important**
>
> When an atomizer model is selected, you will not specify initial diameter, velocity, and position quantities for the particles due to the complexities of sheet and ligament breakup. Instead of initial conditions, the quantities you will specify for the atomizer models are global parameters.

These dependent variables (temperature, diameter, and so on) are updated according to the equations of motion (Particle Motion Theory in the Theory Guide) and according to the heat/mass transfer relations applied (Laws for Heat and Mass Exchange in the Theory Guide) as the particle/droplet moves along its trajectory. You can define any number of different sets of initial conditions for discrete phase particles/droplets provided that your computer has sufficient memory.

For the setup of transient particle cases, the point properties for mass flow and velocity can be specified using transient profiles (see Point Properties for Transient Injections (p. 1300)).

23.3.1. Injection Types

ANSYS Fluent provides 11 types of injections:

- single
- group
- cone (only in 3D)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- surface
- plain-orifice atomizer
- pressure-swirl atomizer
- air-blast-atomizer
- flat-fan-atomizer
- effervescent-atomizer
- file
- condensate

For each nonatomizer injection type, you will specify each of the initial conditions listed in Setting Initial Conditions for the Discrete Phase (p. 1265), the type of particle that possesses these initial conditions, and any other relevant parameters for the particle type chosen.

You should create a single injection when you want to specify a single value for each of the initial conditions (Figure 23.9: Particle Injection Defining a Single Particle Stream (p. 1267)). Create a group injection (Figure 23.10: Particle Injection Defining an Initial Spatial Distribution of the Particle Streams (p. 1268)) when you want to define a range for one or more of the initial conditions (for example, a range of diameters or a range of initial positions). To define cone injections in 3D problems, create a cone injection and specify a particle release pattern (point, hollow, ring, or solid) (Figure 23.11: Particle Injection Defining an Initial Spray Distribution of the Particle Velocity (p. 1268)). To release particles from a surface (either a zone surface or a surface you have defined using **Create** in the **Setting Up Domain** ribbon tab (**Surface**group box)), you will create a surface injection. (If you create a surface injection, a particle stream will be released from each facet of the surface. You can use the **Bounded** and **Sample Points** options in the **Plane Surface** dialog box to create injections from a rectangular mesh of particles in 3D (see Plane Surfaces (p. 1722) for details). If you are modeling film condensation, use the **condensate** injection type to define the vapor-liquid material pair and other modeling settings for the film condensation process.

Figure 23.9: Particle Injection Defining a Single Particle Stream

Figure 23.10: Particle Injection Defining an Initial Spatial Distribution of the Particle Streams

Figure 23.11: Particle Injection Defining an Initial Spray Distribution of the Particle Velocity

Particle initial conditions (position, velocity, diameter, temperature, and mass flow rate) can also be read from an external file if none of the injection types listed above can be used to describe your injection distribution.

The inputs for setting injections are described in detail in Defining Injection Properties (p. 1286).

23.3.2. Particle Types

When you define a set of initial conditions (as described in Defining Injection Properties (p. 1286)), you will need to specify the type of particle. The particle types available to you depend on the range of physical models that you have defined.

- A **massless** particle is a discrete element that follows the flow and temperature of the continuous phase. As it has no mass, it has no associated physical properties, and no force is exerted on it. However, you can assign a User-Defined Law to be applied to the massless particle. The massless particle type is available with all ANSYS Fluent models.

- An **inert** particle is a discrete phase element (particle, droplet, or bubble) that obeys the force balance (Equation 16.1 in the Theory Guide) and is subject to heating or cooling via Law 1 (Inert Heating or Cooling (Law 1/Law 6) in the Theory Guide). The inert type is available for all ANSYS Fluent models.

- A **droplet** particle is a liquid droplet in a continuous-phase gas flow that obeys the force balance (Equation 16.1 in the Theory Guide) and that experiences heating/cooling via Law 1 followed by vaporization and boiling via Laws 2 and 3 (Droplet Vaporization (Law 2) and Droplet Boiling (Law 3) in the Theory Guide). The droplet type is available when heat transfer is being modeled and at least two chemical species are active or the non-premixed or partially premixed combustion model is active. You should use the ideal gas law to define the gas-phase density (in the **Create/Edit Materials** dialog box, as discussed in Density Inputs for the Incompressible Ideal Gas Law (p. 484)) when you select the droplet type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- A **combusting** particle is a solid particle that obeys the force balance (Equation 16.1), and, after an initial phase of inert heating (Law 1), undergoes devolatization (Devolatilization (Law 4)) and then a heterogeneous surface reaction via Law 5 (Surface Combustion (Law 5) in the Theory Guide). Finally, the nonvolatile portion of a combusting particle is subject to inert heating via Law 6. You can also include an evaporating material with the combusting particle by selecting the **Wet Combustion** option in the Set Injection Properties Dialog Box (p. 2796). This allows you to include a material that evaporates and boils via Laws 2 and 3 (Droplet Vaporization (Law 2) and Droplet Boiling (Law 3) in the Theory Guide) before devolatilization of the particle material begins. The combusting type is available when heat transfer is being modeled and at least three chemical species are active or the non-premixed combustion model is active. You should use the ideal gas law to define the gas-phase density (in the Create/Edit Materials Dialog Box (p. 2302)) when you select the combusting particle type.

- A **multicomponent** particle is, as the name implies, a droplet particle containing a mixture of several components or species. The conservation equations of all components, the energy equation, and vapor-liquid-equilibrium at the multicomponent particle surface form a coupled system of differential equations. Law 7, the multicomponent law (Multicomponent Particle Definition (Law 7) in the Theory Guide) is used for such systems. You should use the volume weighted mixing law to define the particle mixture density (in the Create/Edit Materials Dialog Box (p. 2302)) when you select the particle-mixture material type.

Particle Type	Description	Laws Activated
Massless	–	–
Inert	inert/heating or cooling	1, 6
Droplet	heating/evaporation/boiling	1, 2, 3, 6
Combusting	heating; evolution of volatiles/swelling; heterogeneous surface reaction	1, 4, 5, 6
Multicomponent	multicomponent droplets/particles	7

23.3.3. Point Properties for Single Injections

For a single injection, you will define the following initial conditions for the particle stream under the **Point Properties** heading (in the Set Injection Properties Dialog Box (p. 2796)):

- position

  Set the x, y, and z positions of the injected stream along the Cartesian axes of the problem geometry in the **X-**, **Y-**, and **Z-Position** fields. (**Z-Position** will appear only for 3D problems.)

- velocity

  Set the x, y, and z components of the stream's initial velocity in the **X-**, **Y-**, and **Z-Velocity** fields. (**Z-Velocity** will appear only for 3D problems.)

- angular velocity (available when particle rotation is enabled (see Particle Rotation (p. 1291)))

  Set the x, y, and z components of the stream's initial velocity in the **X-**, **Y-**, and **Z-Angular-Velocity** fields. (Only **Z-Angular-Velocity** will appear for 2D problems, because rotation in 2D occurs in the plane, that is, the rotation vector is normal to the plane.)

- diameter

  Set the initial diameter of the injected particle stream in the **Diameter** field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- temperature

  Set the initial (absolute) temperature of the injected particle stream in the **Temperature** field.

- mass flow rate

  For coupled phase calculations (see Solution Strategies for the Discrete Phase (p. 1325)), set the mass of particles per unit time that follows the trajectory defined by the injection in the **Flow Rate** field. Note that in axisymmetric problems the mass flow rate is defined per 2π radians and in 2D problems per unit meter depth (regardless of the reference value for length).

- duration of injection

  For unsteady particle tracking (see Steady/Transient Treatment of Particles (p. 1242)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields. The values you enter are for one complete engine cycle. In subsequent cycles, the injection will be started and stopped according to Equation 10.30 (p. 716), where θ_{event} corresponds to the injection start or end crank angle.

For the massless particle type, you will only need to define the position of the injection. The particle injection velocity is set by the solver equal to the velocity of the continuous phase at the injection point.

If you want to randomly distribute the initial placement of the particles, you can enable **Stagger Positions** and specify **Stagger Radius** to define the particle release region. For more information on spatial staggering, see Staggering of Particles in Space and Time (p. 1264). This option is disabled by default.

23.3.4. Point Properties for Group Injections

For group injections, you will define the properties position, velocity, angular velocity (available when particle rotation is enabled (see Particle Rotation (p. 1291))), diameter, temperature, and flow rate for the **First Point** and **Last Point** in the group. That is, you will define a range of values, ϕ_1 through ϕ_N, for each initial condition ϕ by setting values for ϕ_1 and ϕ_N. ANSYS Fluent assigns a value of ϕ to the i^{th} injection in the group using a linear variation between the first and last values for ϕ:

$$\phi_i = \phi_1 + \frac{\phi_N - \phi_1}{N-1}(i-1) \tag{23.7}$$

Thus, for example, if your group consists of 5 particle streams and you define a range for the initial x location from 0.2 to 0.6 meters, the initial x location of each stream is as follows:

- Stream 1: $x = 0.2$ meters
- Stream 2: $x = 0.3$ meters
- Stream 3: $x = 0.4$ meters
- Stream 4: $x = 0.5$ meters

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Stream 5: $x = 0.6$ meters

Important

In general, you should supply a range for only one of the initial conditions in a given group—leaving all other conditions fixed while a single condition varies among the stream numbers of the group. Otherwise you may find, for example, that your simultaneous inputs of a spatial distribution and a size distribution have placed the small droplets at the beginning of the spatial range and the large droplets at the end of the spatial range.

The specified flow rate is defined per particle stream and can also be interpolated using Equation 23.7 (p. 1270). When a Rosin-Rammler sized distribution is specified the total flow rate will be specified.

For the massless particle type, you will only need to define the first and last point of the injection group position. The particle velocities are set by the solver equal to the velocity of the continuous phase at the injection points.

Note that you can use a different method for defining the size distribution of the particles, as discussed below.

To randomly distribute the initial placement of the particles, enable **Stagger Positions** and specify **Stagger Radius** to define the particle release region. For more information on spatial staggering, see Staggering of Particles in Space and Time (p. 1264). This option is disabled by default.

23.3.5. Point Properties for Cone Injections

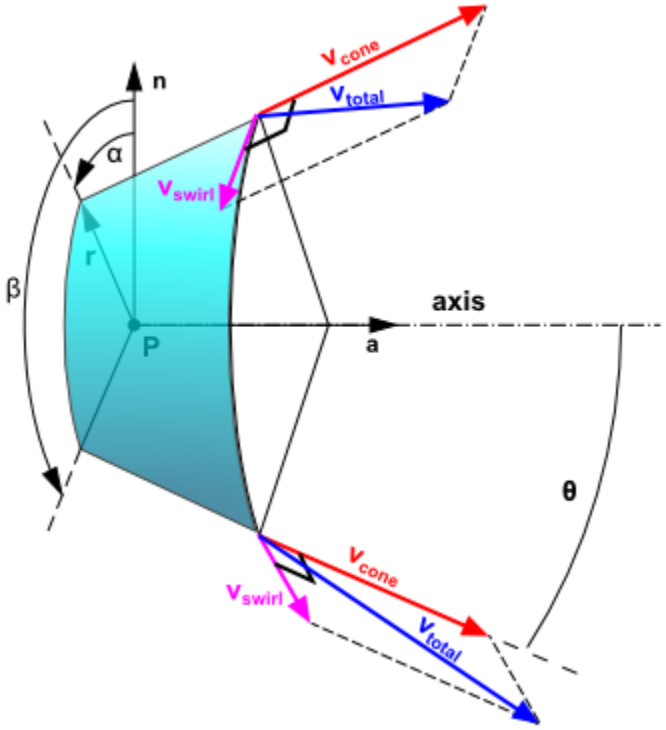
In 3D problems, you can define the following types of particle stream cones:

- **point-cone**
- **hollow-cone**
- **ring-cone**
- **solid-cone**

The particles are released from a 2D region that may be a point, a circle, or an annulus. Its geometry, location, and orientation as well as the shape of the spray cone are defined by the injection parameters. Once you select a cone injection type from the **Cone Type** drop-down list, (in the **Point Properties** tab of the **Set Injection Properties** dialog box), the parameters specific to the selected injection type will be displayed. These inputs are summarized below. Refer to Figure 23.12: Cone Injector Geometry (p. 1272) for an illustration of the geometry.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.12: Cone Injector Geometry



- position

  Set the coordinates of the origin of the spray cone in the **X-**, **Y-**, and **Z-Position** fields (P in Figure 23.12: Cone Injector Geometry (p. 1272))

- diameter

  Set the diameter of the particles in the stream in the **Diameter** field.

- temperature

  Set the temperature of the streams in the **Temperature** field.

- duration of injection

  For unsteady particle tracking (see Steady/Transient Treatment of Particles (p. 1242)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.

- axis

  Set the x, y, and z components of the vector defining the cone's axis in the **X-Axis**, **Y-Axis**, and **Z-Axis** fields. (a in Figure 23.12: Cone Injector Geometry (p. 1272))

- velocity

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set the velocity magnitude of the particle streams that will be oriented along the specified spray cone in the **Velocity Magnitude** field. (v_{total} in Figure 23.12: Cone Injector Geometry (p. 1272))

Note

This is the total spray velocity magnitude and includes any swirl component in a hollow cone injector.

$$\vec{v}_{total}=\vec{v}_{cone}+\vec{v}_{swirl}$$

- angular velocity

  Set the angular velocity magnitude of the particle streams that will be oriented along the specified spray cone in the **Angular Velocity Magnitude** field.

- cone angle

  Set the included half-angle of the spray cone in the **Cone Angle** field. (θ in Figure 23.12: Cone Injector Geometry (p. 1272))

- radii

  For **hollow-cone**, **ring-cone**, and **solid-cone** injections, specify the **Outer Radius**.

  For **ring-cone** injections, specify a nonzero **Inner Radius** to model injectors that do not emanate from a single point. The particles will be distributed about the axis with the specified radius. (r in Figure 23.12: Cone Injector Geometry (p. 1272))

- swirl fraction (hollow cone only)

  Set the swirl fraction, which determines the relative magnitude of the swirl velocity, in the **Swirl Fraction** field.

  $$SF \equiv \frac{|\vec{v}_{swirl}|}{|\vec{v}_{cone}|+|\vec{v}_{swirl}|}$$

  The direction of the swirl component is defined using the right-hand rule about the cone axis (a negative value for the swirl fraction can be used to reverse the swirl direction).

- mass flow rate

  For coupled calculations, set the total mass flow rate for the streams in the spray cone in the **Total Flow Rate** field. Note that for a 3D sector, the flow rate must be appropriate for the sector defined by the **Azimuthal Start Angle** and **Azimuthal Stop Angle**.

- azimuthal angles

  For 3D sectors, set the **Azimuthal Start Angle** and **Azimuthal Stop Angle** to define the sector. (α and β, respectively, in Figure 23.12: Cone Injector Geometry (p. 1272)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **Azimuthal Start Angle** and **Azimuthal Stop Angle** are specified with respect to a reference vector, $\vec{n}$, that is orthogonal to both the cone axis and the global X axis. The reference vector, $\vec{n}$, can be determined as the cross product of the cone axis and the global X axis.

$$\vec{n}=\vec{a}\times\hat{i}$$

where $\hat{i}$ is a unit vector along the global X axis. In the case that the cone axis is along the X axis, then $\vec{n}$ is along the Y axis.

In addition to the above parameters, you can select the following options:

- **Uniform Massflow Distribution** (**solid-cone** or **ring-cone**): Specifies a uniform spacial distribution of mass over the cross-section of a cone. This is especially important when the mesh cell size is smaller than the particle diameter or another characteristic size. This option is enabled by default.
- **Stagger Positions**: Specifies a random spatial distribution of particle steams. For **hollow-cone** injections you must also specify **Stagger Radius** to define the region over which particle release points are staggered in space. For more information on spatial staggering, see Staggering of Particles in Space and Time (p. 1264). This option is disabled by default.

The distribution of the velocity directions in the particle streams for the point-cone, ring-cone, and solid-cone injections is random. Furthermore, duplicating this injection may not necessarily result in the same distribution, at the same location.

Important

For transient calculations, the spatial distribution of streams at the initial injection location is recalculated at each time step. Sampling different possible trajectories allows a more accurate representation of a point, ring, or solid cone using fewer computational parcels. For steady-state calculations, the trajectories are initialized one time and kept the same for subsequent DPM iterations. The trajectories are recalculated when a change in the **Injections** dialog box occurs or when a case and data file are saved. If the residuals and solution change when a small change is made to the injection or when a case and data file are saved, it may mean that there are not enough trajectories being used to represent the point, ring, or solid cone with sufficient accuracy.

Note that you may want to define multiple spray cones emanating from the same initial location in order to specify a known size distribution of the spray or to include a known range of cone angles.

For the massless particle type, you will only need to define position, axis, cone angle, azimuthal angles, and radius. The particle velocities are set by the solver equal to the velocity of the continuous phase at the injection points.

23.3.6. Point Properties for Surface Injections

For surface injections, you will define all the properties described in Point Properties for Single Injections (p. 1269) for single injections except for the initial position of the particle streams. The initial positions of the particles will be the location of the data points on the specified surface(s). Note that you will set the **Total Flow Rate** of all particles released from the surface (required for coupled calculations only). If you want, you can scale the individual mass flow rates of the particles by the ratio of the area of the face they are released from to the total area of the surface. To scale the mass flow rates, select the **Scale Flow Rate By Face Area** option under **Point Properties**. For the massless particle type, you will not

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

need to enter any information to define a surface injection. The particle velocities are set by the solver equal to the velocities of the continuous phase at the injection points.

Note that many surfaces have nonuniform distributions of points. If you want to generate a uniform spatial distribution of particle streams released from a surface in 3D, you can create a bounded plane surface with a uniform distribution using the Plane Surface Dialog Box (p. 2777), as described in Plane Surfaces (p. 1722). In 2D, you can create a rake using the Line/Rake Surface Dialog Box (p. 2727), as described in Line and Rake Surfaces (p. 1718).

In addition to the option of scaling the flow rate by the face area, the normal direction of a face can be used for the injection direction. To use the face normal direction for the injection direction, select the **Inject Using Face Normal Direction** option under **Point Properties** (Figure 23.19: Setting Surface Injection Properties (p. 1288)). Once this option is selected, you only need to specify the velocity magnitude of the injection, not the individual components of the velocity magnitude.

Important

- Only surface injections from boundary surfaces will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used.
- For moving or deforming mesh simulations, only zonal surfaces can be selected.

A nonuniform size distribution can be used for surface injections, as described below.

23.3.6.1. Using the Rosin-Rammler Diameter Distribution Method

The Rosin-Rammler size distributions described in Using the Rosin-Rammler Diameter Distribution Method (p. 1281) for group injections is also available for surface injections. If you select one of the Rosin-Rammler distributions (**rosin-rammler** or **rosin-rammler-logarithmic**), you will need to specify the following parameters under **Point Properties**, in addition to the initial velocity, temperature, and total flow rate:

- **Min. Diameter**

  This is the smallest diameter to be considered in the size distribution.

- **Max. Diameter**

  This is the largest diameter to be considered in the size distribution.

- **Mean Diameter**

  This is the size parameter, $\overline{d}$, in the Rosin-Rammler equation (Equation 23.9 (p. 1281)).

- **Spread Parameter**

  This is the exponential parameter, n, in Equation 23.9 (p. 1281).

- **Number of Diameters**

  This is the number of diameters in each distribution (that is, the number of different diameters in the stream injected from each face of the surface).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ANSYS Fluent will inject streams of particles from each face on the surface, with diameters defined by the Rosin-Rammler distribution function. The total number of injection streams tracked for the surface injection will be equal to the number of diameters in each distribution (**Number of Diameters**) multiplied by the number of faces on the surface.

23.3.7. Point Properties for Plain-Orifice Atomizer Injections

For a plain-orifice atomizer injection, you will define the following initial conditions under **Point Properties**:

- position

  Set the x, y, and z positions of the injected stream along the Cartesian axes of the problem geometry in the **X-Position**, **Y-Position**, and **Z-Position** fields. (**Z-Position** will appear only for 3D problems).

- axis (3D only)

  Set the x, y, and z components of the vector defining the axis of the orifice in the **X-Axis**, **Y-Axis**, and **Z-Axis** fields.

- temperature

  Set the temperature of the streams in the **Temperature** field.

- mass flow rate

  Set the total mass flow rate for the streams in the atomizer in the **Flow Rate** field. Note that in 3D sectors, the flow rate must be appropriate for the sector defined by the **Azimuthal Start Angle** and **Azimuthal Stop Angle**.

- duration of injection

  For unsteady particle tracking (see Steady/Transient Treatment of Particles (p. 1242)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.

- vapor pressure

  Set the vapor pressure governing the flow through the internal orifice (p_v in Table 16.4: List of Governing Parameters for Internal Nozzle Flow in the Theory Guide) in the **Vapor Pressure** field.

- diameter

  Set the diameter of the orifice in the **Injector Inner Diameter** field (d in Table 16.4: List of Governing Parameters for Internal Nozzle Flow in the Theory Guide).

- orifice length

  Set the length of the orifice in the **Orifice Length** field (L in Table 16.4: List of Governing Parameters for Internal Nozzle Flow in the Theory Guide).

- radius of curvature

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set the radius of curvature of the inlet corner in the **Corner Radius of Curvature** field (r in Table 16.4: List of Governing Parameters for Internal Nozzle Flow in the Theory Guide).

- nozzle parameter

  Set the constant for the spray angle correlation in the **Constant A** field (C_A in Equation 16.331 in the Theory Guide).

- azimuthal angles

  For 3D sectors, set the **Azimuthal Start Angle** and **Azimuthal Stop Angle**.

See The Plain-Orifice Atomizer Model in the Theory Guide for details about how these inputs are used.

If you want to randomly distribute the initial placement of the particles, enable **Stagger Positions** (default). The region over which particle release points will be staggered is defined by the specified orifice diameter. For more information on spatial staggering, see Staggering of Particles in Space and Time (p. 1264).

23.3.8. Point Properties for Pressure-Swirl Atomizer Injections

For a pressure-swirl atomizer injection, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate, duration of injection (if unsteady), injector inner diameter, and azimuthal angles (if relevant) described in Point Properties for Plain-Orifice Atomizer Injections (p. 1276), you will need to specify the following parameters under **Point Properties**:

- spray angle

  Set the value of the spray angle of the injected stream in the **Spray Half Angle** field (θ in Equation 16.343 in the Theory Guide).

- pressure

  Set the absolute pressure upstream of the injection in the **Upstream Pressure** field (p_1 in Table 16.4: List of Governing Parameters for Internal Nozzle Flow in the Theory Guide).

- sheet breakup

  Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Sheet Constant** field ($\ln\left(\frac{\eta_b}{\eta_0}\right)$ in Equation 16.350 in the Theory Guide).

- ligament diameter

  For short waves, set the proportionality constant that linearly relates the ligament diameter, d_L, to the wavelength that breaks up the sheet in the **Ligament Constant** field (see Equation 16.351—Equation 16.354 in the Theory Guide).

- dispersion angle

  For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** for a flat fan atomizer is depicted in Figure 23.13: Flat Fan Viewed from Above and from the Side (p. 1280).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See The Pressure-Swirl Atomizer Model in the Theory Guide for details about how these inputs are used.

23.3.9. Point Properties for Air-Blast/Air-Assist Atomizer Injections

For an air-blast/air-assist atomizer, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate, duration of injection (if unsteady), injector inner diameter, and azimuthal angles (if relevant) described in Point Properties for Plain-Orifice Atomizer Injections (p. 1276), you will need to specify the following parameters under **Point Properties**:

- outer diameter

  Set the outer diameter of the injector in the **Injector Outer Diameter** field. This value is used in conjunction with the **Injector Inner Diameter** to set the thickness of the liquid sheet (t in Equation 16.337 in the Theory Guide).

- spray angle

  Set the initial trajectory of the film as it leaves the end of the orifice in the **Spray Half Angle** field (θ in Equation 16.343 in the Theory Guide).

- relative velocity

  Set the maximum relative velocity that is produced by the sheet and air in the **Relative Velocity** field.

- sheet breakup

  Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Sheet Constant** field ($\ln\left(\frac{\eta_b}{\eta_0}\right)$ in Equation 16.350 in the Theory Guide).

- ligament diameter

  For short waves, set the proportionality constant (C_L in Equation 16.353 in the Theory Guide) that linearly relates the ligament diameter, d_L, to the wavelength that breaks up the sheet in the **Ligament Constant** field.

- dispersion angle

  For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** for a flat fan atomizer is depicted in Figure 23.13: Flat Fan Viewed from Above and from the Side (p. 1280).

See The Air-Blast/Air-Assist Atomizer Model in the Theory Guide for details about how these inputs are used.

23.3.10. Point Properties for Flat-Fan Atomizer Injections

The flat-fan atomizer model is available only for 3D models. For this type of injection, you will define the following initial conditions under **Point Properties**:

- arc position

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Set the coordinates of the center point of the arc from which the fan originates in the **X-Center**, **Y-Center**, and **Z-Center** fields (see Figure 23.13: Flat Fan Viewed from Above and from the Side (p. 1280)).

- virtual position

  Set the coordinates of the virtual origin of the fan in the **X-Virtual Origin**, **Y-Virtual Origin**, and **Z-Virtual Origin** fields. This point is the intersection of the lines that mark the sides of the fan (see Figure 23.13: Flat Fan Viewed from Above and from the Side (p. 1280)).

- normal vector

  Set the direction that is normal to the fan in the **X-Fan Normal Vector**, **Y-Fan Normal Vector**, and **Z-Fan Normal Vector** fields.

- temperature

  Set the temperature of the streams in the **Temperature** field.

- mass flow rate

  Set the mass flow rate for the streams in the atomizer in the **Flow Rate** field.

- duration of injection

  For unsteady particle tracking (see Steady/Transient Treatment of Particles (p. 1242)), set the starting and ending time for the injection in the **Start Time** and **Stop Time** fields. When In-Cylinder mesh motion is enabled, set the starting and ending crank angles for the injection in the **Start Crank Angle** and **Stop Crank Angle** fields.

- spray half angle

  Set the initial half angle of the drops as they leave the end of the orifice in the **Spray Half Angle** field.

- orifice width

  Set the width of the orifice (in the normal direction) in the **Orifice Width** field.

- sheet breakup

  Set the value of the empirical constant that determines the length of the ligaments that are formed after sheet breakup in the **Flat Fan Sheet Constant** field (see Equation 16.350 in the Theory Guide).

- dispersion angle

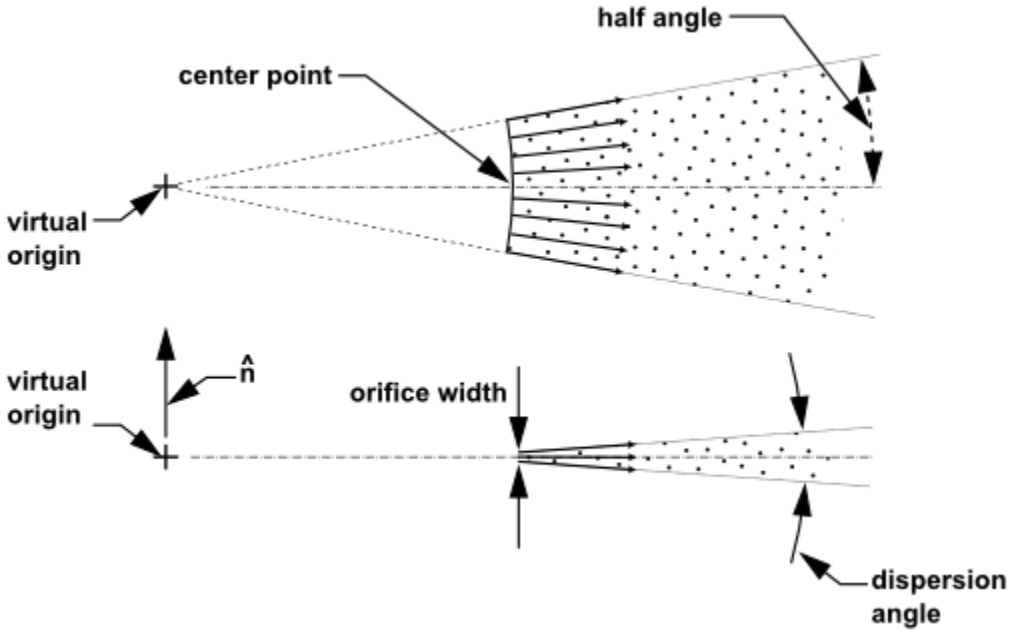
  For a smooth distribution of the droplets, the initial velocities is varied within this dispersion angle. A sketch of the **Atomizer Dispersion Angle** is depicted in Figure 23.13: Flat Fan Viewed from Above and from the Side (p. 1280).

See The Flat-Fan Atomizer Model in the Theory Guide for details about how these inputs are used.

To randomly distribute the initial placement of the particles, enable **Stagger Positions** (default). The orifice width is used as radius to define the region over which particle release points will be staggered in space. For more information on spatial staggering, see Staggering of Particles in Space and Time (p. 1264).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.13: Flat Fan Viewed from Above and from the Side



23.3.11. Point Properties for Effervescent Atomizer Injections

For an effervescent atomizer injection, you will specify some of the same properties as for a plain-orifice atomizer. In addition to the position, axis (if 3D), temperature, mass flow rate (including both flashing and non-flashing components), duration of injection (if unsteady), vapor pressure, injector inner diameter, and azimuthal angles (if relevant) described in Point Properties for Plain-Orifice Atomizer Injections (p. 1276), you will need to specify the following parameters under **Point Properties**:

- mixture quality

  Set the mass fraction of the injected mixture that vaporizes in the **Mixture Quality** field (x in Equation 16.360 in the Theory Guide).

- saturation temperature

  Set the saturation temperature of the volatile substance in the **Saturation Temp.** field.

- droplet dispersion

  Set the parameter that controls the spatial dispersion of the droplet sizes in the **Dispersion Constant** field (C_{eff} in Equation 16.360 in the Theory Guide).

- spray angle

  Set the initial trajectory of the film as it leaves the end of the orifice in the **Maximum Half Angle** field.

See The Effervescent Atomizer Model in the Theory Guide for details about how these inputs are used.

23.3.12. Point Properties for File Injections

The file for a file injection has the following form:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
(( x y z u v w diameter temperature mass-flow) name )
```

with all of the parameters in SI units. All the parentheses are required, but the name is optional.

Sample files generated during sampling of trajectories for steady particles (see Sampling of Trajectories (p. 1355)) can also be used as injection files since they have a similar file format.

23.3.13. Point Properties for Condensate Injections

For a condensate injection, you will define only the duration of the injection by setting the starting and ending time for the injection in the **Start Time** and **Stop Time** fields under the **Point Properties** tab in the **Set Injection Properties** dialog box. The duration of the injection determines the time during which film condensation will be initiated on the walls that have the **Film Condensation** option enabled.

23.3.14. Using the Rosin-Rammler Diameter Distribution Method

For liquid sprays, a convenient representation of the droplet size distribution is the Rosin-Rammler expression. The complete range of sizes is divided into an adequate number of discrete intervals; each represented by a mean diameter for which trajectory calculations are performed. If the size distribution is of the Rosin-Rammler type, the mass fraction of droplets of diameter greater than d is given by

$$Y_d = e^{-(d/\bar{d})^n} \tag{23.8}$$

where $\bar{d}$ is the size constant and n is the size distribution parameter.

By default, you will define the size distribution of particles by inputting a diameter for the first and last points and using the linear equation (Equation 23.7 (p. 1270)) to vary the diameter of each particle stream in the group. When you want a different mass flow rate for each particle/droplet size, however, the linear variation may not yield the distribution you need. Your particle size distribution may be defined most easily by fitting the size distribution data to the Rosin-Rammler equation. In this approach, the complete range of particle sizes is divided into a set of discrete size ranges, each to be defined by a single stream that is part of the group. Assume, for example, that the particle size data obeys the following distribution:

Diameter Range (μm)	Mass Fraction in Range
0–70	0.05
70–100	0.10
100–120	0.35
120–150	0.30
150–180	0.15
180–200	0.05

The Rosin-Rammler distribution function is based on the assumption that an exponential relationship exists between the droplet diameter, d, and the mass fraction of droplets with diameter greater than d, Y_d:

$$Y_d = e^{-(d/\bar{d})^n} \tag{23.9}$$

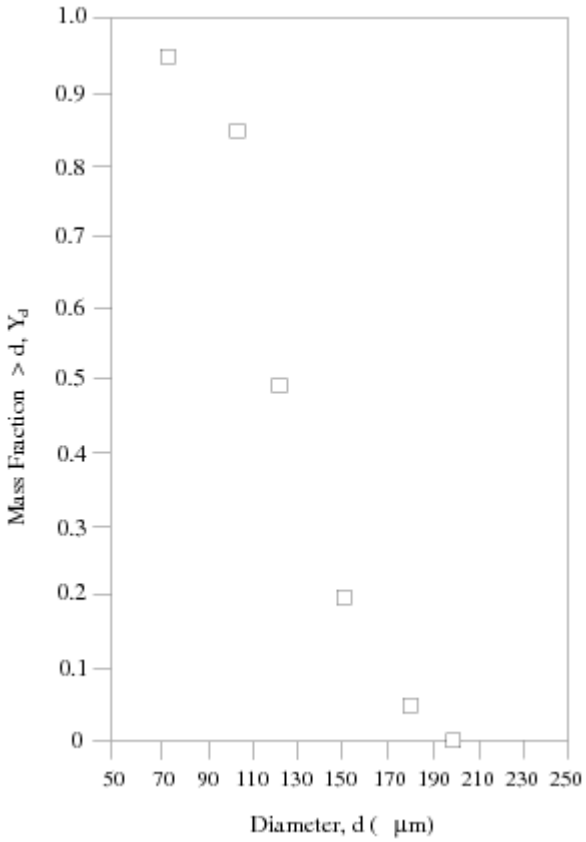
ANSYS Fluent refers to the quantity $\bar{d}$ in Equation 23.9 (p. 1281) as the **Mean Diameter** and to n as the **Spread Parameter**. These parameters are specified by you (in the Set Injection Properties Dialog Box (p. 2796) under the **First Point** heading) to define the Rosin-Rammler size distribution. To solve for

these parameters, you must fit your particle size data to the Rosin-Rammler exponential equation. To determine these inputs, first recast the given droplet size data in terms of the Rosin-Rammler format. For the example data provided above, this yields the following pairs of d and Y_d:

Diameter, d (μm)	**Mass Fraction with Diameter Greater than d, Y_d**
70	0.95
100	0.85
120	0.50
150	0.20
180	0.05
200	(0.00)

A plot of Y_d vs. d is shown in Figure 23.14: Example of Cumulative Size Distribution of Particles (p. 1282).

Figure 23.14: Example of Cumulative Size Distribution of Particles



Next, derive values of $\bar{d}$ and n such that the data in Figure 23.14: Example of Cumulative Size Distribution of Particles (p. 1282) fit Equation 23.9 (p. 1281). The value for $\bar{d}$ is obtained by noting that this is the value of d at which $Y_d = e^{-1} \approx 0.368$. From Figure 23.14: Example of Cumulative Size Distribution of Particles (p. 1282), you can estimate that this occurs for $d \approx 131 \mu$m. The numerical value for n is given by

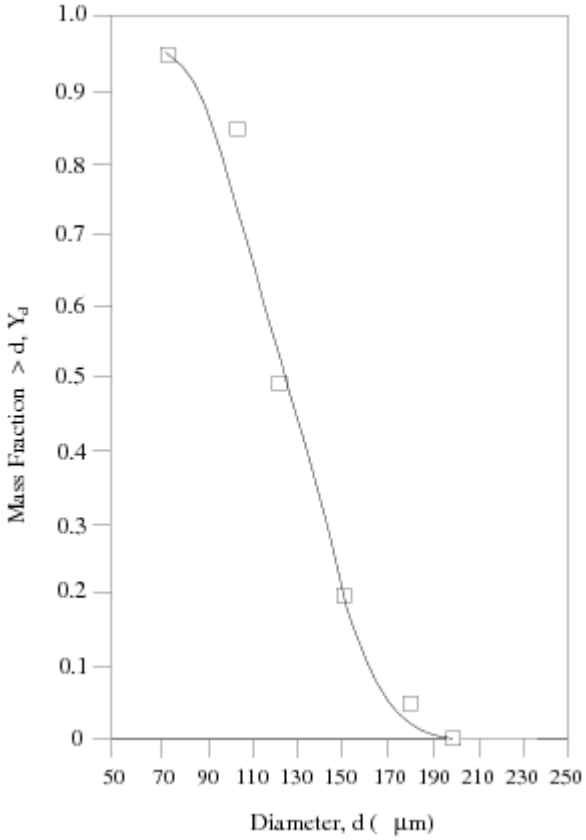
$$n = \frac{\ln\left(-\ln Y_d\right)}{\ln\left(d/\bar{d}\right)} \tag{23.10}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By substituting the given data pairs for Y_d and $d / \overline{d}$ into this equation, you can obtain values for n and find an average. Doing so yields an average value of $n = 4.52$ for the example data above. The resulting Rosin-Rammler curve fit is compared to the example data in Figure 23.15: Rosin-Rammler Curve Fit for the Example Particle Size Data (p. 1283). You can enter values for $\overline{d}$ and n, as well as the diameter range of the data and the total mass flow rate for the combined individual size ranges, using the Set Injection Properties Dialog Box (p. 2796).

This technique of fitting the Rosin-Rammler curve to spray data is used when reporting the Rosin-Rammler diameter and spread parameter in the **Discrete Phase Summary** dialog box in Summary Reporting of Current Particles (p. 1358).

Figure 23.15: Rosin-Rammler Curve Fit for the Example Particle Size Data



A second Rosin-Rammler distribution is also available based on the natural logarithm of the particle diameter. If in your case, the smaller-diameter particles in a Rosin-Rammler distribution have higher mass flows in comparison with the larger-diameter particles, you may want better resolution of the smaller-diameter particle streams, or "bins". You can therefore choose to have the diameter increments in the Rosin-Rammler distribution done uniformly by $\ln d$.

In the standard Rosin-Rammler distribution, a particle injection may have a diameter range of 1 to 200 μm. In the logarithmic Rosin-Rammler distribution, the same diameter range would be converted to a range of $\ln 1$ to $\ln 200$, or about 0 to 5.3. In this way, the mass flow in one bin would be less-heavily skewed as compared to the other bins.

When a Rosin-Rammler size distribution is being defined for the group of streams, you should define (in addition to the initial velocity, position, and temperature) the following parameters, which appear under the heading for the **First Point**:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Total Flow Rate**

  This is the total mass flow rate of the N streams in the group. Note that in axisymmetric problems this mass flow rate is defined per 2π radians and in 2D problems per unit meter depth.

- **Min. Diameter**

  This is the smallest diameter to be considered in the size distribution.

- **Max. Diameter**

  This is the largest diameter to be considered in the size distribution.

- **Mean Diameter**

  This is the size parameter, $\overline{d}$, in the Rosin-Rammler equation (Equation 23.9 (p. 1281)).

- **Spread Parameter**

  This is the exponential parameter, n, in Equation 23.9 (p. 1281).

23.3.14.1. The Stochastic Rosin-Rammler Diameter Distribution Method

For atomizer injections, a Rosin-Rammler distribution is assumed for the particles exiting the injector. In order to decrease the number of particles necessary to accurately describe the distribution, the diameter distribution function is randomly sampled for each instance where new particles are introduced into the domain.

The Rosin-Rammler distribution can be written as

$$1-Y=\exp\left[-\left(\frac{D}{\overline{d}}\right)^{n}\right] \tag{23.11}$$

where Y is the mass fraction smaller than a given diameter D, $\overline{d}$ is the Rosin-Rammler diameter and n is the Rosin-Rammler exponent. This expression can be inverted by taking logs of both sides and rearranging,

$$D=\overline{d}\left(-\ln\left(1-Y\right)\right)^{1/n}. \tag{23.12}$$

Given a mass fraction Y along with parameters $\overline{d}$ and n, this function will explicitly provide a diameter, D. Diameters for the atomizer injectors described in Point Properties for Plain-Orifice Atomizer Injections (p. 1276) are obtained by uniformly sampling Y in Equation 23.12 (p. 1284).

23.3.15. Creating and Modifying Injections

You will use the **Injections** branch of the tree and the Injections Dialog Box (p. 2716) (Figure 23.17: The Injections Dialog Box (p. 1285), Figure 23.16: The Injections Branch of the Tree (p. 1285)) to create, copy, delete, list, read, and write injections.

Setup → Models → Discrete Phase → Injections → New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.16: The Injections Branch of the Tree

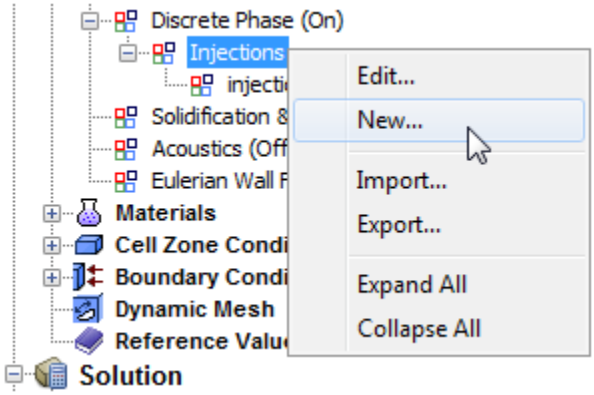


Figure 23.17: The Injections Dialog Box

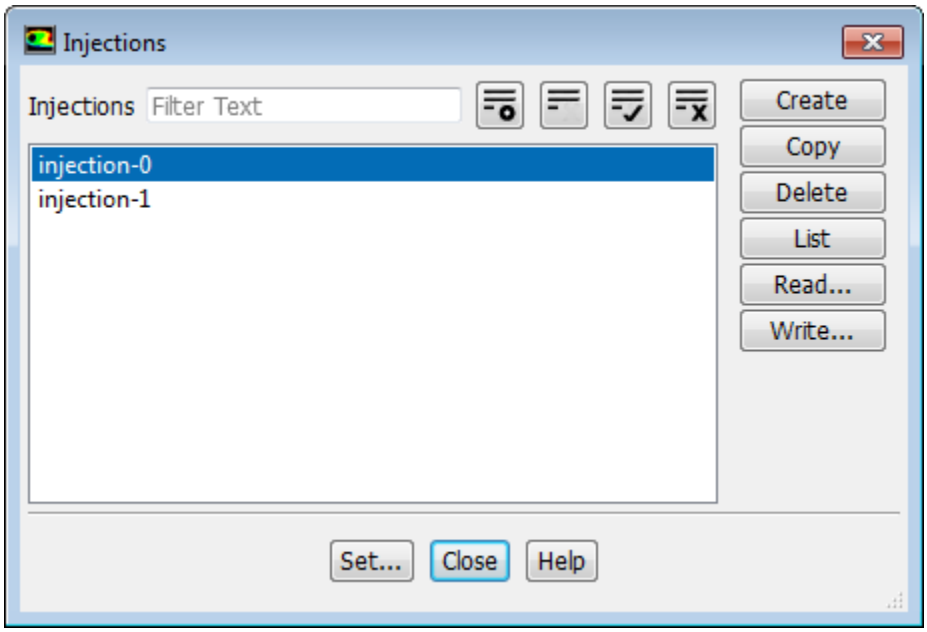


(You can also click the **Injections...** button in the Discrete Phase Model Dialog Box (p. 2278) to open the **Injections** dialog box.)

23.3.15.1. Creating Injections

To create an injection, click the **Create** button. The Set Injection Properties Dialog Box (p. 2796) will open automatically to allow you to set the injection properties (as described in Defining Injection Properties (p. 1286)). After the injection is created, the new injection will appear in the **Injections** list, in the **Injections** dialog box.

23.3.15.2. Modifying Injections

To modify an existing injection, select its name in the **Injections** list and click the **Set...** button. The **Set Injection Properties** dialog box will open, and you can modify the properties as needed.

If you have two or more injections for which you want to set some of the same properties, select their names in the **Injections** list and click the **Set...** button. The **Set Multiple Injection Properties** dialog

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

box will open, which will allow you to set the common properties. For instructions about using this dialog box, see Defining Properties Common to More than One Injection (p. 1297).

23.3.15.3. Copying Injections

To copy an existing injection to a new injection, select the existing injection in the **Injections** list and click the **Copy** button. The Set Injection Properties Dialog Box (p. 2796) will open with a new injection that has the same properties as the injection you selected. This is useful if you want to set another injection with similar properties.

23.3.15.4. Deleting Injections

You can delete an injection by selecting its name in the **Injections** list and clicking the **Delete** button.

23.3.15.5. Listing Injections

To list the initial conditions for the particle streams in the selected injection, click the **List** button. ANSYS Fluent reports the initial conditions (in SI units) in the console under various columns:

- The particle stream number is in the column headed `NO`.
- The particle type (`IN` for inert, `DR` for droplet, or `CP` for combusting particle) is in the column headed `TYP`.
- The x, y, and z positions are in the columns headed `(X)`, `(Y)`, and `(Z)`.
- The x, y, and z velocities are in the columns headed `(U)`, `(V)`, and `(W)`.
- The temperature is in the column headed `(T)`.
- The diameter is in the column headed `(DIAM)`.
- The mass flow rate in the column headed `(MFLOW)`.

23.3.15.6. Reading and Writing Injections

To transfer information about DPM injections from one case file to another, use the **Read...** and **Write...** buttons. You can write selected injections to a file, which can be read into a different ANSYS Fluent session, simplifying the setup of new case files. To write the injection, select the injection from the list, then click **Write...**. The Select File Dialog Box (p. 19) will open where you can enter the name of your injection file. To read in an injection, click **Read...** to open The Select File Dialog Box (p. 19) where you will select the injection file to read in. If the injection that you imported has the same name as that in your current case, then ANSYS Fluent will rename the imported injection.

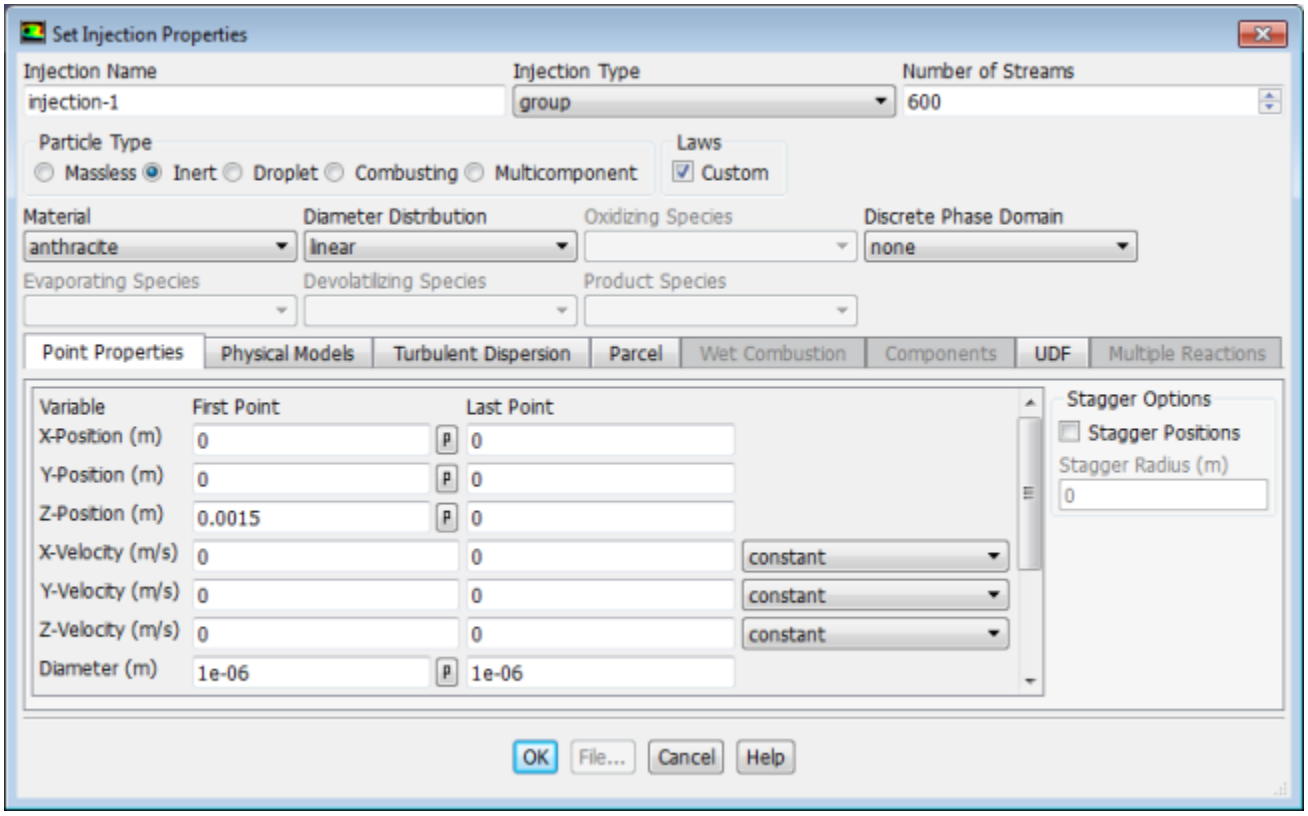
After reading injections, you may need to visit the **Injections** dialog box to modify the settings for the injection material and the DPM laws since the presumed settings may have changed in the current case file setup.

23.3.16. Defining Injection Properties

Once you have created an injection (using the Injections Dialog Box (p. 2716), as described in Creating and Modifying Injections (p. 1284)), you will use the Set Injection Properties Dialog Box (p. 2796) (Figure 23.18: The Set Injection Properties Dialog Box (p. 1287)) to define the injection properties. (Remember that this dialog box will open when you create a new injection, or when you select an existing injection and click the **Set...** button in the **Injections** dialog box.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.18: The Set Injection Properties Dialog Box



The procedure for defining an injection is as follows:

1. If you want to change the default name of the injection, enter a new name in the **Injection Name** field. This is recommended if you are defining a large number of injections so you can easily distinguish them. When assigning names to your injections, keep in mind the selection shortcut described in Creating and Modifying Injections (p. 1284).

2. Choose the type of injection in the **Injection Type** drop-down list. The injection choices (**single**, **group**, **cone**, **surface**, **plain-orifice-atomizer**, **pressure-swirl-atomizer**, **air-blast-atomizer**, **flat-fan-atomizer**, **effervescent-atomizer**, **condensate**, and **file**) are described in Injection Types (p. 1266). Note that if you select any of the atomizer models, you also must set the **Viscosity** and **Droplet Surface Tension** in the **Create/Edit Materials** dialog box.

   Important

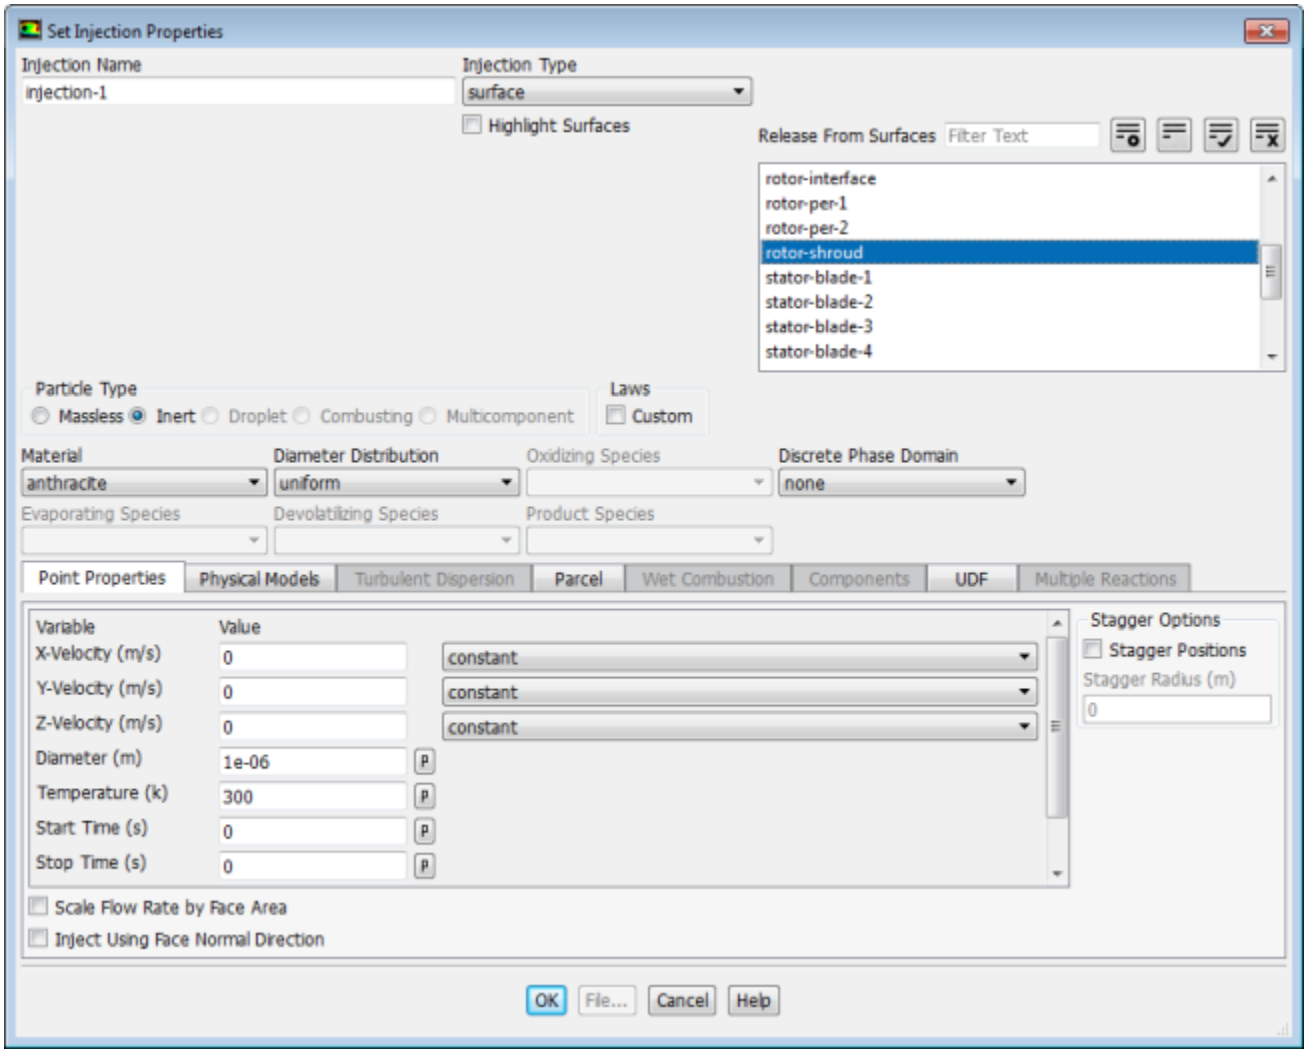
   Note that only surface injections from boundary surfaces will be moved with the mesh when a sliding mesh or a moving or deforming mesh is being used.

3. If you are defining a **single** or **condensate** injection, go to the next step. For a **group**, **cone**, or any of the **atomizer** injections, set the **Number of Streams** in the group, spray cone, or atomizer.

   If you are defining a **surface** injection (see Figure 23.19: Setting Surface Injection Properties (p. 1288)), choose the surface(s) from which the particles will be released in the **Release From Surfaces** list. If you are reading the injection from a file, click the **File...** button at the bottom of the Set Injection Properties Dialog Box (p. 2796) and specify the file to be read in the resulting **Select File** dialog box. The parameters in the injection file must be in SI units.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.19: Setting Surface Injection Properties



4. Select **Massless**, **Inert**, **Droplet**, **Combusting**, or **Multicomponent** as the **Particle Type**. The available types are described in Particle Types (p. 1268). Note that for the **condensate** injection, the only available particle types are **Droplet** and **Multicomponent**.

5. Choose the material for the particle(s) in the **Material** drop-down list.

   If this is the first time you have created a particle of this type, you can choose from all of the materials of this type defined in the database. If you have already created a particle of this type, the only available material will be the material you selected for that particle. You can define additional materials by copying them from the database or creating them from scratch, as discussed in Setting Discrete-Phase Physical Properties (p. 1316) and described in detail in Using the **Create/Edit Materials** Dialog Box (p. 461).

   Important

   Note that you will not choose a **Material** for a **Massless** particle type.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

6. If you are defining a **group**, **cone**, or **surface** injection and you want to change from the default **linear** (for group injections) or **uniform** (for cone and surface injections) interpolation method used to determine the size of the particles, select **rosin-rammler** or **rosin-rammler-logarithmic** in the **Diameter Distribution** drop-down list. The Rosin-Rammler method for determining the range of diameters for a group injection is described in Using the Rosin-Rammler Diameter Distribution Method (p. 1281).

7. If you have created a customized particle law using user-defined functions, enable the **Custom** option under **Laws** and specify the appropriate laws as described in Custom Particle Laws (p. 1296).

8. If your particle type is **Inert**, go to the next step. If you are defining **Droplet** particles, select the gas phase species created by the vaporization and boiling laws (Laws 2 and 3) in the **Evaporating Species** drop-down list.

   If you are defining **Combusting** particles, select the gas phase species created by the devolatilization law (Law 4) in the **Devolatilizing Species** drop-down list, the gas phase species that participates in the surface char combustion reaction (Law 5) in the **Oxidizing Species** list, and the gas phase species created by the surface char combustion reaction (Law 5) in the **Product Species** list. Note that if the **Combustion Model** for the selected combusting particle material (in the **Create/Edit Materials** dialog box) is the **multiple-surface-reaction** model, then the **Oxidizing Species** and **Product Species** lists will be disabled because the reaction stoichiometry has been defined in the mixture material.

   If you are defining **Multicomponent** particles, maw 7 will go into effect. Notice that the **Components** tab will become active when this particle type is selected. See below for information on the **Components** tab.

9. Click the **Point Properties** tab (the default), and specify the point properties (position, velocity, diameter, temperature, and—if appropriate—mass flow rate and any atomizer-related parameters) as described for each injection type in Point Properties for Single Injections (p. 1269) – Point Properties for Effervescent Atomizer Injections (p. 1280).

   For surface injections, you can enable the **Scale Flow Rate by Face Area** and you can choose the injection direction. To use the face normal direction for the injection direction, select the **Inject Using Face Normal Direction** option under **Point Properties** (Figure 23.19: Setting Surface Injection Properties (p. 1288)). Once this option is selected, you only need to specify the velocity magnitude of the injection, not the individual components of the velocity magnitude.

10. If you want to set up injection-specific physics models such as drag laws, Brownian motion, and breakup, click the **Physical Models** tab and configure the injection physics models as described in Specifying Injection-Specific Physical Models (p. 1290).

11. If the flow is turbulent and you want to include the effects of turbulence on the particle dispersion, click the **Turbulent Dispersion** tab, enable the **Discrete Random Walk Model** under **Stochastic tracking** or the **Cloud Model**, and set the related parameters as described in Specifying Turbulent Dispersion of Particles (p. 1294).

12. If you have enabled **Unsteady Particle Tracking**, you can define settings for how the parcels are released. Click the **Parcel** tab and select a **Parcel Release Method** from the drop-down list. The default method is **standard**, in which a single parcel is released per injection stream per time step. Alternatively can choose **constant-number**, **constant-mass**, or **constant-diameter**. Refer to Steady/Transient Treatment of Particles (p. 1242) for details of these methods.

13. If your combusting particle includes an evaporating material, click the **Wet Combustion** tab, select the **Wet Combustion Model** option, and then select the material that is evaporating/boiling from the particle

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

before devolatilization begins in the **Liquid Material** drop-down list. You should also set the volume fraction of the liquid present in the particle by entering the value of the **Liquid Fraction**. Finally, select the gas phase species created by the evaporating and boiling laws in the **Evaporating Species** drop-down list in the top part of the dialog box.

14. If you include multicomponent droplets as the material in your discrete phase model, the **Components** tab will become active. In this tab, you will specify the **Mass Fraction** of each of the components. Note that the sum of the mass fractions should add up to unity, otherwise ANSYS Fluent will adjust the values such that you have a sum of 1 for the mass fraction, and will prompt you to accept the entry. Under **Evaporating Species**, select **not-vaporizing** if the component in the particle does not vaporize. Otherwise, select the species that will be vaporized.

    To change the components of the multicomponent droplet:

    a. In the **Create/Edit Materials** dialog box, either define a new droplet materials or copy appropriate materials from the Fluent materials database.

    b. Click **Edit...** next to **Mixture Species**.

    c. In the **Species** dialog box, add the droplet materials that you have copied or defined to the **Selected Species** list and remove unwanted materials.

15. If you want to use a user-defined function to initialize the injection properties, click the **UDF** tab to access the UDF inputs. You can select an **Initialization** function under **User-Defined Functions** to modify injection properties at the time the particles are injected into the domain. This allows the position and/or properties of the injection to be set as a function of flow conditions. More information about user-defined functions can be found in the Fluent Customization Manual.

16. If you have defined more than one particle surface species, for example, carbon (**C<s>**) and sulfur (**S<s>**), you will need to specify the mass fraction of each particle surface species in the combusting particle. To do so, click the **Multiple Reactions** tab, and enter the **Species Mass Fractions**. These mass fractions refer to the combustible fraction of the combusting particle, and should sum to 1. If there is only one surface species in the mixture material, the mass fraction of that species will be set to 1, and you will not specify anything under **Multiple Surface Reactions**.

23.3.17. Specifying Injection-Specific Physical Models

Drag and breakup models can be specified on a per-injection basis, allowing you to specify the most appropriate models for each injection in your model. These per-injection models are specified on the **Physical Models** tab of the **Set Injection Properties** dialog box.

23.3.17.1. Drag Laws

The **spherical**, **nonspherical**, **Stokes-Cunningham**, and **high-Mach-number** laws described in Particle Force Balance in the Theory Guide are always available, and the **dynamic-drag** law described in Dynamic Drag Model Theory in the Theory Guide is available only when one of the droplet breakup models is used in conjunction with unsteady tracking. See Breakup (p. 1292) for information about enabling the droplet breakup models. The **Grace** and **Ishii-Zuber** drag laws described in Bubbly Flow Drag Laws in the *Fluent Theory Guide* allow to model the drag coefficient in gas-liquid flows in which the bubbles can have a range of different shapes. Both drag laws are only available if the magnitude and direction of the gravity vector are specified in the **Operating Conditions** dialog box. The remaining three, **Wen-Yu**, **Gidaspow**, and **Syamlal-OBrien** are available only when the dense discrete phase model is enabled (Including the Dense Discrete Phase Model (p. 1481)) and the flow regime consists of a dense gas-solid.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

However, with these models, you cannot verify whether it really is a dense flow or a gas-solid flow. It is up to you to decide. In any case, these drag formulations are suitable for dense gas-solid flows.

If the **spherical**, **high-Mach-number**, **dynamic-drag**, **Wen-Yu**, **Gidaspow**, or **Syamlal-OBrien** drag law is selected, no further inputs are required. If the **nonspherical** law is selected, the particle **Shape Factor** (ϕ in Equation 16.75 in the Theory Guide) must be specified. The shape factor value cannot exceed 1. For the **Stokes-Cunningham** law, the **Cunningham Correction** factor (C_c in Equation 16.77 in the Theory Guide) must be specified.

23.3.17.2. Particle Rotation

To set-up particle rotation, follow the steps below:

1. In the **Set Injection Properties** dialog box, under the **Physical Models** tab, enable **Particle Rotation**.

   The options related to the particle rotation feature appear in the **Set Injection Properties** dialog box.

2. From the **Rotational Drag Law** drop-down list, select the model for calculating the rotational drag coefficient C_ω. The following options are available:

   Dennis-et-al
   Uses Equation 16.4 in the *Fluent Theory Guide* to calculate the rotational drag coefficient C_ω.

   none (default)
   Implies zero torque, that is, it excludes the influence of the fluid on the rotational particle motion.

3. From the **Magnus Lift Law** drop-down list, select the model for calculating the rotational lift coefficient C_{RL}. The following models are available:

   Oesterle-Bui-Dinh
   Uses Oesterle and Bui Dinh's formulation (Equation 16.18 in the *Fluent Theory Guide*).

   Tsuji-et-al
   Is based on the particle spin rate (Equation 16.19 in the *Fluent Theory Guide*).

   Rubinow-Keller
   Uses a linear dependence of the rotational lift coefficient C_{RL} on the spin rate (Equation 16.21 in the *Fluent Theory Guide*).

   none (default)
   Implies that the Magnus lift will not be included in your simulation.

4. Under the **Point Properties** tab, specify angular velocity components for **single**, **group**, and **surface** injections; and angular velocity magnitudes for **cone** injections.

5. For each wall with a **reflect** boundary condition for the discrete phase, specify the friction coefficient (μ in Equation 16.209 and Equation 16.214 in the *Fluent Theory Guide*) under the **DPM** tab of the **Wall** dialog box. For details, see Friction Coefficient (p. 1305).

The particle rotation model options are also accessible through the text user interface, under `define/models/dpm/injections/injection-properties/set/physical-models/particle-rotation`. Note that the `physical-models` command becomes available only

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

after you have selected the injection(s) using the prompts of the `define/models/dpm/injections/properties/set/pick-injections-to-set` text command.

23.3.17.3. Rough Wall Model

To use the rough wall model for walls with the **reflect** boundary condition type:

1. In the **Injection Settings** dialog box, under the **Physical Models** tab, select **Rough Wall Model**.
2. In the **Wall** boundary conditions dialog box for the appropriate wall, under the **DPM** tab, select **reflect** from the **Boundary Cond. Type** drop-down list.
3. Specify the following wall roughness parameters:

   Ra
   is the wall mean roughness (R_a in Equation 16.216 in the *Fluent Theory Guide*)

   Rq
   is the standard deviation of the roughness structure (R_q in Equation 16.216 in the *Fluent Theory Guide*)

   RSm
   is the mean roughness slope (the average distance between peaks of wall material) (RS_m in Equation 16.216 in the *Fluent Theory Guide*)

   Note

   Note that the **DPM Wall Roughness Parameters** will only appear in the **Wall** dialog box with the `reflect` DPM boundary condition type if the **Rough Wall Model** is selected in the **Injection Settings** dialog box.

For information about the rough wall model, see Rough Wall Model in the *Fluent Theory Guide*.

23.3.17.4. Brownian Motion Effects

For sub-micron particles in laminar flow, you may want to include the effects of Brownian motion (described in Brownian Force in the Theory Guide) on the particle trajectories. To do so, enable the **Brownian Motion** option under the **Physical Models** tab. In order to include Brownian motion effects, you must also select the **Stokes-Cunningham** drag law in the **Drag Law** drop-down list under **Drag Parameters**, and specify the **Cunningham Correction** (C_c in Equation 16.77 in the Theory Guide).

23.3.17.5. Breakup

To enable the modeling of particle breakup for the injection, select **Enable Breakup** and choose the **Breakup Model** (**TAB**, **Wave**, **KHRT**, or **SSD**) from the drop-down list. A detailed description of these models can be found in Secondary Breakup Model Theory in the Theory Guide.

- For the **TAB** model, you must specify the following values:
  - **y0** is the initial distortion at time equal to zero (y_0 in Equation 16.367 in the Theory Guide). The default value ($y_0=0$) is recommended.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  – The number of **Breakup Parcels** (under the **Breakup Model** drop-down list), to split the droplet into several child parcels, as described in Velocity of Child Droplets in the Theory Guide. The diameter of the child parcels is sampled from a Rosin-Rammler distribution. This can be switched off in the TUI with the command:

    ```
    /define/models/dpm/spray-model/tab-randomize-breakup-parcel-diameter?
    ```

- For the **Wave** model, you must specify the following values:

  – **B0** is the constant B_0 in Equation 16.397 in the Theory Guide.

  – **B1** is the constant B_1 in Equation 16.399 in the Theory Guide.

  Note

  You will generally not need to modify the value of **B0**, as the default value 0.61 is acceptable for nearly all cases. A value of 1.73 is recommended for **B1**.

  The **Wave** model implementation has been formulated to deal with the initial breakup of a cylindrical liquid jet. In the Rayleigh regime (that is, at low gas Weber numbers), a cylindrical jet breaks up into droplets whose diameters are larger than that of the jet itself. In this regime, the model assumes that the diameter of the continuous, cylindrical liquid jet has been entered as initial diameter in the injection. Therefore, the droplet diameter can grow beyond the initial diameter. For details, see Droplet Breakup in the *Fluent Theory Guide*.

  If you want to suppress this feature of the Wave model, use the TUI command:

  ```
  /define/models/dpm/spray-model/wave-allow-rayleigh-growth? no
  ```

  Note that this takes effect unconditionally for all injections using the **Wave** or **KHRT** breakup models.

- For the **KHRT** model, you must specify the following values:

  – **B0** is the constant B_0 in Equation 16.397 in the Theory Guide.

  – **B1** is the constant B_1 in Equation 16.399 in the Theory Guide.

  – **Ctau** is the constant C_τ in Equation 16.404 in the Theory Guide.

  – **CRT** is the constant C_{RT} in Equation 16.405 in the Theory Guide.

  – **CL** is the constant C_L in Equation 16.400 in the Theory Guide.

  The constants **B0** and **B1** are the same as for the Wave model.

  As for the **Wave** model described above, the **KHRT** model is formulated to deal with the initial breakup of a cylindrical liquid jet. The behavior in the Rayleigh regime is as described above for the **Wave** model and the same TUI command can be used to modify the behavior. In addition, the **KHRT** model uses the Liquid Core Approximation as described in Liquid Core Length in the *Fluent Theory Guide*. To suppress the use of the Liquid Core Approximation you can set the Levich constant, C_L, to zero.

- For the **SSD** model, you must specify the following values:

  – **Critical We** is the critical Weber number in Equation 16.406 in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– **Core B1** is B in Equation 16.407 in the Theory Guide.

– **Target Np** is the number of droplets given to each child parcel, before scaling is used to give the correct overall mass.

– **Xi** is $\langle \xi \rangle$ in Equation 16.408 in the Theory Guide.

> **Note**
>
> **Xi** is a negative value: exp(Xi) is a typical factor by which daughter particles are smaller than the original parcel.

For steady-state simulations, you also must specify an appropriate **Particle Time Step Size** and the **Number of Time Steps**, which will control the spray density. See Options for Interaction with the Continuous Phase (p. 1241) for more information.

Note that you may want to use the dynamic drag law when you use one of the breakup models. See Drag Laws (p. 1249) for information about choosing the drag law.

23.3.18. Specifying Turbulent Dispersion of Particles

As mentioned in Defining Injection Properties (p. 1286), you can choose for each injection stochastic tracking or cloud tracking as the method for modeling turbulent dispersion of particles.

23.3.18.1. Stochastic Tracking

For turbulent flows, if you choose to use the stochastic tracking technique, you must enable the **Discrete Random Walk Model** and specify the **Number of Tries**. Stochastic tracking includes the effect of turbulent velocity fluctuations on the particle trajectories using the DRW model described in Stochastic Tracking in the Theory Guide.

1. Click the **Turbulent Dispersion** tab in the **Set Injection Properties** dialog box.

2. Enable stochastic tracking by turning on the **Discrete Random Walk Model** under **Stochastic Tracking**.

3. Specify the **Number of Tries**:

   Selecting the **Turbulent Dispersion** model tells ANSYS Fluent to include turbulent velocity fluctuations in the particle force balance as in Equation 16.22 in the Theory Guide. The trajectory is computed more than once if your input exceeds 1: two trajectory calculations are performed if you enter 2, three trajectory calculations are performed if you enter 3, and so on. Each trajectory calculation includes a new stochastic representation of the turbulent contributions to the trajectory equation.

   When a sufficient number of tries is requested, the trajectories computed will include a statistical representation of the spread of the particle stream due to turbulence. Note that for unsteady particle tracking, the **Number of Tries** is set to 1 if using stochastic tracking.

If you want the characteristic lifetime of the eddy to be random (Equation 16.33 in the Theory Guide), enable the **Random Eddy Lifetime** option. You will generally not need to change the **Time Scale Constant** (C_L in Equation 16.24 in the Theory Guide) from its default value of 0.15, unless you are using the Reynolds Stress turbulence model (RSM), in which case a value of 0.3 is recommended.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.20: Mean Trajectory in a Turbulent Flow (p. 1295) illustrates a discrete phase trajectory calculation computed without turbulent dispersion and Figure 23.21: Stochastic Trajectories in a Turbulent Flow (p. 1295) illustrates the "stochastic" tracking (number of tries ≥ 1) option.

When multiple stochastic trajectory calculations are performed, the momentum and mass defined for the injection are divided evenly among the multiple particle/droplet tracks, and are therefore spread out in terms of the interphase momentum, heat, and mass transfer calculations. Including turbulent dispersion in your model can thus have a significant impact on the effect of the particles on the continuous phase when coupled calculations are performed.

Figure 23.20: Mean Trajectory in a Turbulent Flow

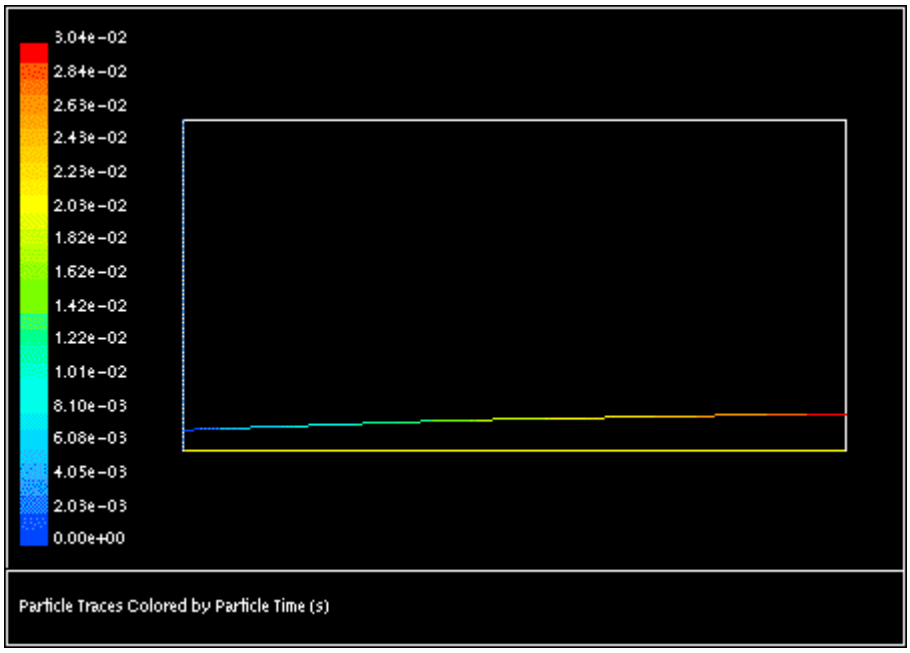


Figure 23.21: Stochastic Trajectories in a Turbulent Flow

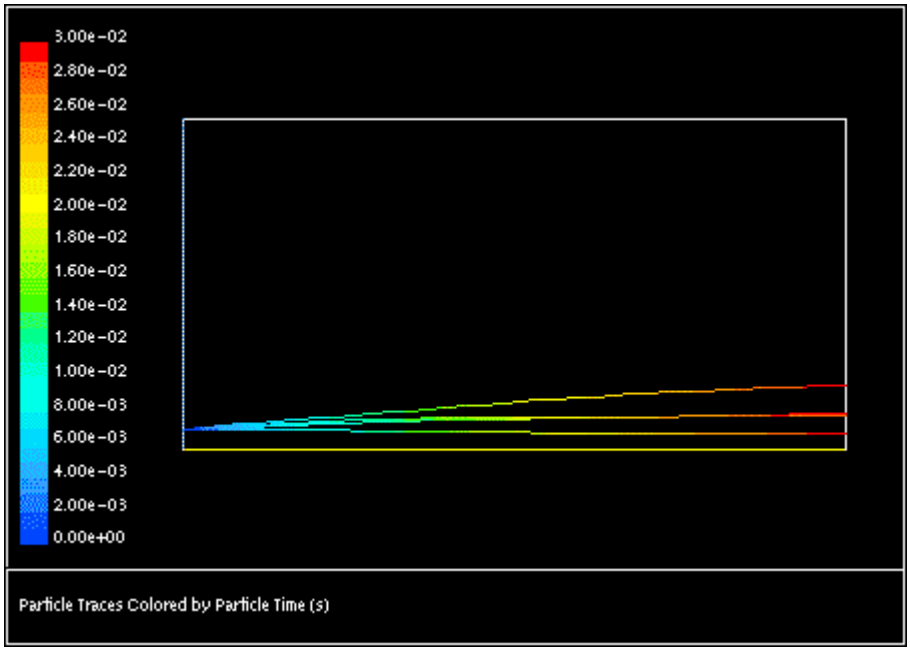


23.3.18.2. Cloud Tracking

For turbulent flows, you can also include the effects of turbulent dispersion on the injection. Note that cloud tracking is not available for the massless particle type. When cloud tracking is used, the trajectory will be tracked as a cloud of particles about a mean trajectory, as described in Particle Cloud Tracking in the Theory Guide.

1. Click the **Turbulent Dispersion** tab in the **Set Injection Properties** dialog box.

2. Enable cloud tracking by turning on the **Cloud Model** under **Cloud Tracking**.

3. Specify the minimum and maximum cloud diameters. Particles enter the domain with an initial cloud diameter equal to the **Min. Cloud Diameter**. The particle cloud's maximum allowed diameter is specified by the **Max. Cloud Diameter**.

   You may want to restrict the **Max. Cloud Diameter** to a relevant length scale for the problem to improve computational efficiency in complex domains where the mean trajectory may become stuck in recirculation regions.

Important

Note that this model is available only in serial or for shared-memory tracking.

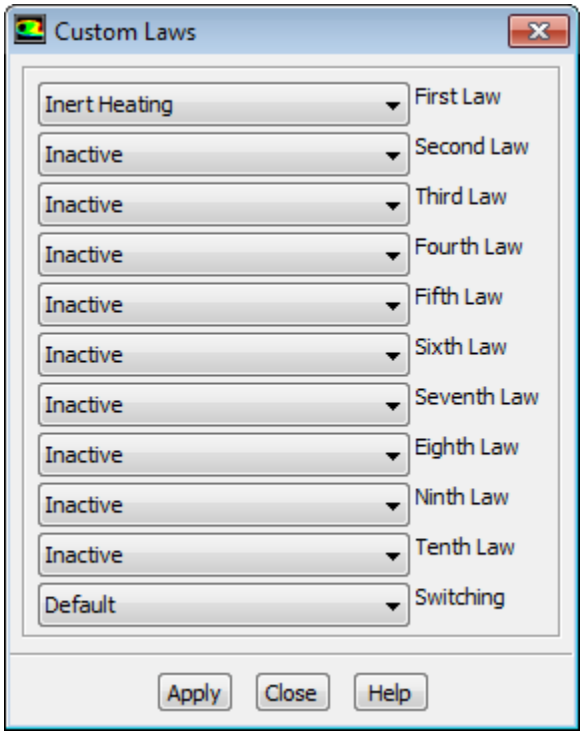
23.3.19. Custom Particle Laws

If the standard ANSYS Fluent laws, Laws 1 through 7, do not adequately describe the physics of your discrete phase model, you can modify them by creating custom laws with user-defined functions. More information about user-defined functions can be found in the Fluent Customization Manual. You can also create custom laws by using a subset of the existing ANSYS Fluent laws (for example, Laws 1, 2, and 4), or a combination of existing laws and user-defined functions.

Once you have defined and loaded your user-defined function(s), you can create a custom law by enabling the **Custom** option under **Laws** in the Set Injection Properties Dialog Box (p. 2796). This will open the Custom Laws Dialog Box (p. 2684). In the drop-down list to the left of each of the particle laws, you can select the appropriate particle law for your custom law. Each list contains the available options that can be chosen (the standard laws plus any user-defined functions you have loaded).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.22: The Custom Laws Dialog Box



There is a final drop-down list in the Custom Laws Dialog Box (p. 2684) labeled **Switching**. You may want to have ANSYS Fluent vary the laws used depending on conditions in the model. You can customize the way ANSYS Fluent switches between laws by selecting a user-defined function from this drop-down list (see `DEFINE_DPM_SWITCH` in the Fluent Customization Manual).

An example of when you might want to use a custom law might be to replace the standard devolatilization law with a specialized devolatilization law that more accurately describes some unique aspects of your model. After creating and loading a user-defined function that details the physics of your devolatilization law, you would visit the Custom Laws Dialog Box (p. 2684) and replace the standard devolatilization law (Law 2) with your user-defined function.

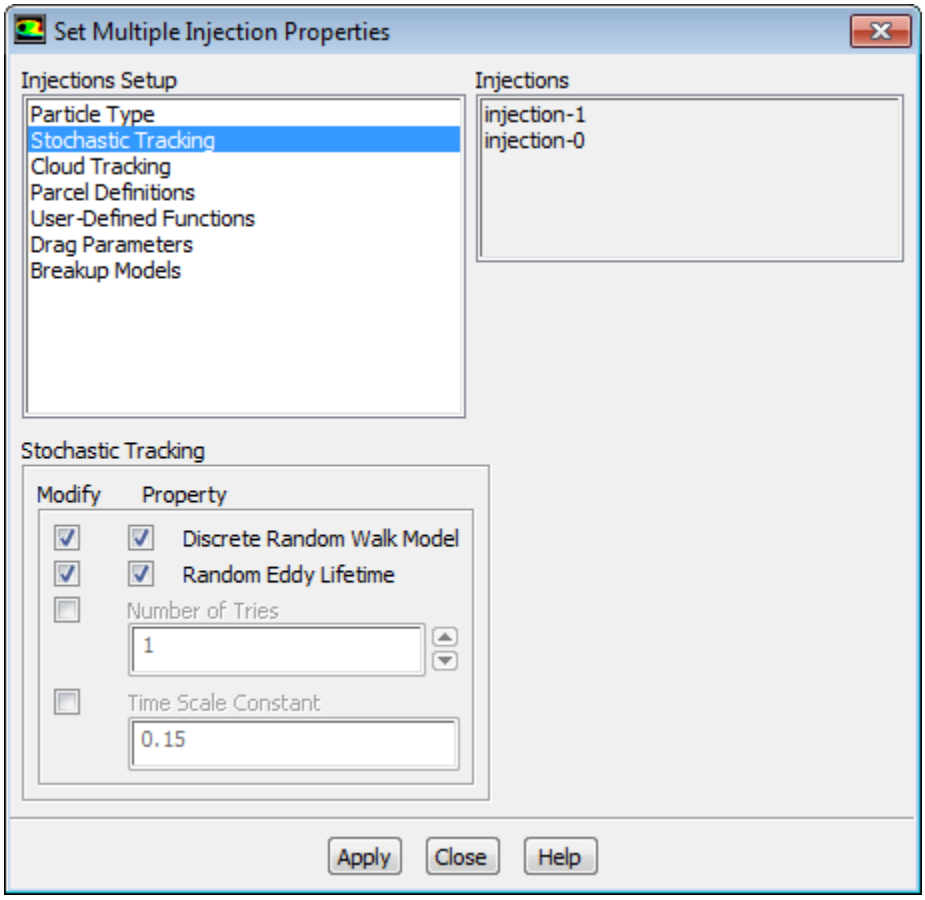
23.3.20. Defining Properties Common to More than One Injection

If you have a number of injections for which you want to set the same properties, ANSYS Fluent provides a shortcut so that you do not need to visit the **Set Injection Properties** dialog box for each injection to make the same changes.

As described in Modifying Injections (p. 1285), if you select more than one injection in the **Injections** dialog box, clicking the **Set...** button will open the **Set Multiple Injection Properties** dialog box (Figure 23.23: The Set Multiple Injection Properties Dialog Box (p. 1298)) instead of the **Set Injection Properties** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.23: The Set Multiple Injection Properties Dialog Box



Depending on the type of injections you have selected (single, group, atomizers, and so on), there will be different categories of properties listed under **Injections Setup**. The names of these categories correspond to the headings within the **Set Injection Properties** dialog box (for example, **Particle Type** and **Stochastic Tracking**). Only those categories that are appropriate for all of your selected injections (which are shown in the **Injections** list) will be listed. If all of these injections are of the same type, more categories of properties will be available for you to modify. If the injections are of different types, you will have fewer categories to select from.

Note

You cannot define any properties as input parameters when you are modifying multiple injections. If you want to specify a property as an input parameter you must use Figure 23.18: The Set Injection Properties Dialog Box (p. 1287).

23.3.20.1. Modifying Properties

To modify a property, perform the following steps:

1. Select the appropriate category in the **Injections Setup** list. For example, if you want to set the same flow rate for all of the selected injections, select **Point Properties**. The dialog box will expand to show the properties that appear under that heading in the **Set Injection Properties** dialog box.

2. Set the property (or properties) to be modified, as described below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Click **Apply**. ANSYS Fluent will report the change in the console window.

Important

You must click **Apply** to save the property settings within each category. If, for example, you want to modify the flow rate and the stochastic tracking parameters, you will need to select **Point Properties** in the **Injections Setup** list, specify the flow rate, and click **Apply**. You would then repeat the process for the stochastic tracking parameters, clicking **Apply** again when you are done.

There are two types of properties that can be modified using the **Set Multiple Injection Properties** dialog box.

The first type involves one of the following actions:

- selecting a value from a drop-down list
- making a selection from a list of radio buttons

The second type involves one of the following actions:

- entering a value in a field
- enabling / disabling an option

Setting the first type of property works the same way as in the **Set Injection Properties** dialog box. For example, if you select **Particle Type** in the **Injections Setup** list, the dialog box will expand to show the portion of the **Set Injection Properties** dialog box where you choose the particle type. You can simply choose the desired type and click **Apply**.

Setting the second type of property requires an additional step. If you select a category in the **Injections Setup** list that contains this type of property, the expanded portion of the dialog box will look like the corresponding part of the **Set Injection Properties** dialog box, with the addition of **Modify** check buttons (see Figure 23.23: The Set Multiple Injection Properties Dialog Box (p. 1298)). To change one of the properties, first turn on the **Modify** check button to its left, and then specify the desired status or value.

For example, if you would like to enable stochastic tracking, first turn on the **Modify** check button to the left of **Stochastic Model**. This will make the property active so you can modify its status. Then, under **Property**, turn on the **Stochastic Model** check button. (Be sure to click **Apply** when you are done setting stochastic tracking parameters.)

If you would like to change the value of **Number of Tries**, select the **Modify** check button to its left to make it active, and then enter the new value in the field. Make sure you click **Apply** when you have finished modifying the stochastic tracking properties.

Important

The setting for a property that has not been enabled with the **Modify** check button is not relevant, because it will not be applied to the selected injections when you click **Apply**. After you enable **Modify** for a particular property, clicking **Apply** will modify that property for all of the selected injections, so make sure that you have the settings the way that you want

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

them before you do this. If you make a mistake, you will have to return to the **Set Injection Properties** dialog box for each injection to fix the incorrect setting, if it is not possible to do so in the **Set Multiple Injection Properties** dialog box.

23.3.20.2. Modifying Properties Common to a Subset of Selected Injections

Note that it is possible to change a property that is relevant for only a subset of the selected injections. For example, if some of the selected injections are using stochastic tracking and some are not, enabling the **Random Eddy Lifetime** option and clicking **Apply** will turn this option on only for those injections that are using stochastic tracking. The other injections will be unaffected.

23.3.21. Point Properties for Transient Injections

Simulations of transient particles often require time dependent injection conditions. Potentially most of the point properties may change over time. One method to accomplish this is the use of an **Initialization** function as described in `DEFINE_DPM_INJECTION_INIT` in the Fluent Customization Manual.

An easier way is to use transient profiles containing one or more variables based on the time or crank angle that can be assigned to various point properties: (Total) **Mass Flow Rate**, **X-, Y-, Z- Velocity**, **Velocity Magnitude,** and **Cone Angle** depending on the injection type selected. See Point Properties for Single Injections (p. 1269) to Point Properties for Effervescent Atomizer Injections (p. 1280) for the description of the individual properties.

Before transient profile variables can be assigned to point properties of injections, a profile file has to be read into ANSYS Fluent using the **File**/**Read**/**Profile...** ribbon tab item. In the **Select File** dialog box a **transient profile** in tabular format with extension `.ttab` has to be chosen. Alternatively, you can read this file into ANSYS Fluent using the `read-transient-table` text command.

`file` → `read-transient-table`

The profile name should not exceed 63 characters. See Defining Transient Cell Zone and Boundary Conditions (p. 448) for the format description. The following example illustrates an injection within 3 intervals of 2.5 milliseconds injection time, where the second injection has an elevated velocity.

```
mv-profile 3 13 0
time         mass-flow    velocity
0            0            0.1
0.00999      0            0.1
0.01         0.001        0.1
0.0125       0.001        0.1
0.01251      0            0.1
0.01999      0            0.1
0.02         0.001        5
0.0225       0.001        5
0.02251      0            0.1
0.02999      0            0.1
0.03         0.001        0.1
0.0325       0.001        0.1
0.03251      0            0.1
```

For the setting of point properties go to the **Point Properties** tab in the **Set Injection Properties** dialog box.

When transient profiles are loaded, you can choose either a **constant** method (the default) or **profile** from the **Method** drop-down list. If you select **profile**, you also must choose a profile from the corres-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ponding drop-down list that appears in the **Value** column. The variable angle or time from the file is used as an independent interpolation variable and cannot be chosen as a profile.

Important

All quantities in the profile file, including coordinate values, must be specified in SI units. Specifically, Mass Flow Rate must be specified in kg/s, Velocity in m/s, and Cone Angle in radians. ANSYS Fluent does not perform unit conversion when reading profile files.

23.4. Setting Boundary Conditions for the Discrete Phase

When a particle reaches a physical boundary (for example, a wall or inlet boundary) in your model, ANSYS Fluent applies a discrete phase boundary condition to determine the fate of the trajectory at that boundary. One of several contingencies may arise:

- The particle may be reflected via an elastic or inelastic collision.
- The particle may escape through the boundary. The particle is lost from the calculation at the point where it impacts the boundary.
- The particle may be trapped at the wall. Nonvolatile material is lost from the calculation at the point of impact with the boundary; volatile material present in the particle or droplet is released to the vapor phase at this point.
- The particle may pass through an internal boundary zone, such as radiator or porous jump.
- The particle may slide along the wall, depending on particle properties and impact angle.
- The particle may form a film (wall film model).

You also have the option of implementing a user-defined function to model the particle behavior when hitting the boundary. More information about user-defined functions can be found in the Fluent Customization Manual.

The boundary condition, or trajectory fate, can be defined separately for each zone in your ANSYS Fluent model.

For additional information, see the following sections:

23.4.1. Discrete Phase Boundary Condition Types
23.4.2. Default Discrete Phase Boundary Conditions
23.4.3. Coefficients of Restitution
23.4.4. Friction Coefficient
23.4.5. Particle-Wall Impingement Heat Transfer
23.4.6. Film Condensation Model
23.4.7. Wall Boundary Layer Model
23.4.8. Setting Particle Erosion and Accretion Parameters

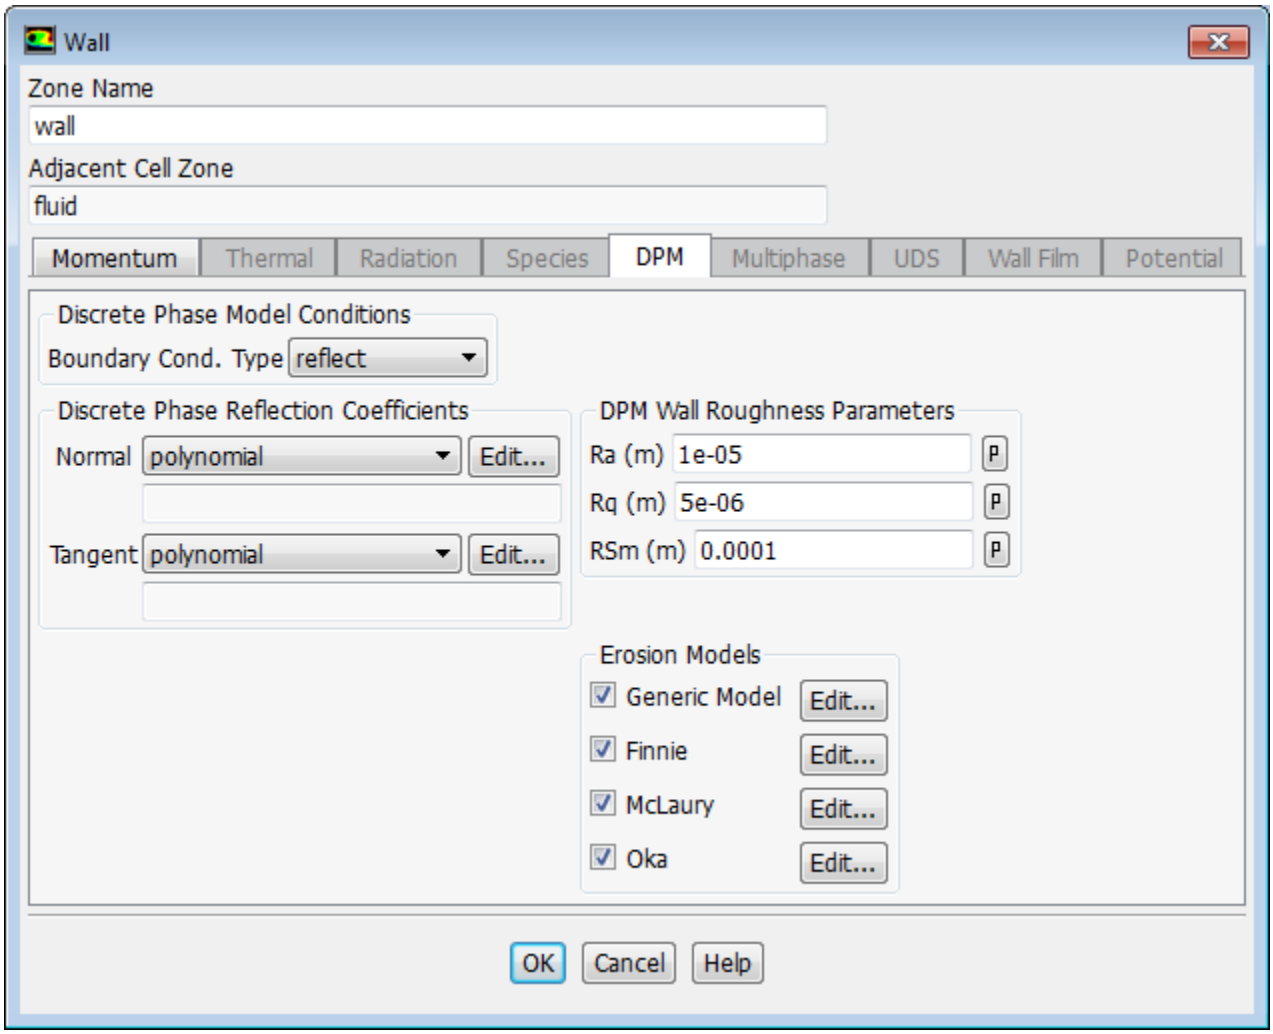
23.4.1. Discrete Phase Boundary Condition Types

Discrete phase boundary conditions can be set for boundaries in the dialog boxes opened from the **Boundary Conditions** task page. When one or more injections have been defined, inputs for the discrete phase will appear in the dialog boxes. In the **Walls** dialog boxes, you will need to click the **DPM** tab to

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

access the **Discrete Phase Model Conditions** as shown in Figure 23.24: Discrete Phase Boundary Conditions in the Wall Dialog Box (p. 1302).

Figure 23.24: Discrete Phase Boundary Conditions in the Wall Dialog Box



The available boundary conditions are:

- `reflect`

  The particle rebounds off the boundary with a change in its momentum. ANSYS Fluent provides two models for computing this change:

  – For non-rotating particles, the momentum depends on the coefficient of restitution (Equation 16.208 in the *Fluent Theory Guide*).

  – For rotating particles, the model proposed by Tsuji et al. 489 is used. The particle rotation model includes frictional effects.

  The details on these two models can be found in Wall-Particle Reflection Model Theory in the *Fluent Theory Guide*.

  For information on how to set up the parameters for non-rotating and rotating particle models, see Coefficients of Restitution (p. 1305) and Friction Coefficient (p. 1305), respectively.

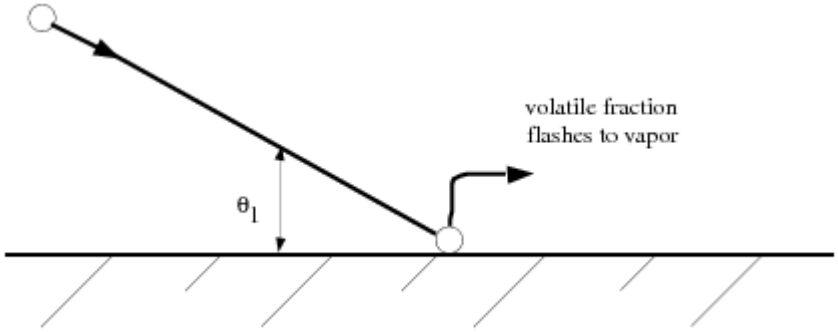
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When at least one injection accounts for the rough wall model (the **Rough Wall Model** option is selected under the **Physical Models** tab in the **Set Injections Properties** dialog box), you can specify the wall surface roughness parameters as described in Rough Wall Model (p. 1292).

- `trap`

  The trajectory calculations are terminated and the fate of the particle is recorded as "trapped". In the case of evaporating droplets, their entire mass instantaneously passes into the vapor phase and enters the cell adjacent to the boundary. See Figure 23.25: "Trap" Boundary Condition for the Discrete Phase (p. 1303). In the case of combusting particles, the remaining volatile mass is passed into the vapor phase.

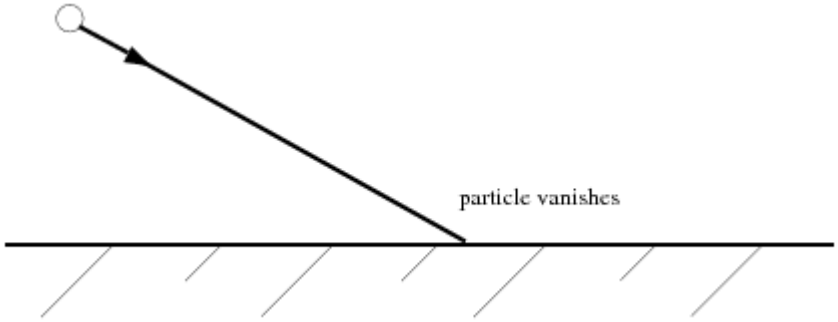
  Figure 23.25: "Trap" Boundary Condition for the Discrete Phase

- `escape`

  The particle is reported as having "escaped" when it encounters the boundary in question. Trajectory calculations are terminated. See Figure 23.26: "Escape" Boundary Condition for the Discrete Phase (p. 1303).

  Figure 23.26: "Escape" Boundary Condition for the Discrete Phase

- `wall-jet`

  The `wall-jet` type boundary condition is appropriate for high-temperature walls where no significant liquid film is formed, and in high-Weber-number impacts where the spray acts as a jet. The model is not appropriate for regimes where film is important (for example, port fuel injection in SI engines, rainwater runoff, and so on).

  A more detailed description of underlying theory is available in Wall-Jet Model Theory in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `wall-film`

  This boundary condition offers the following two impingement models:

  `stanton-rutland`: (default) consists of four regimes, namely, stick, rebound, spread, and splash, which are based on the impact energy and wall temperature. See The Stanton-Rutland Model in the *Fluent Theory Guide* for more details.

  `kuhnke`: consists of four regimes spread, rebound, splash, and dry splash (thermal breakup). See The Kuhnke Model in the *Fluent Theory Guide* for more details.

  For the `kuhnke` model, you must specify the following **DPM Wall Roughness Parameters**:

  Roughness Ra: is used to compute K_{cold} in Equation 16.258 in the *Fluent Theory Guide*.

  Roughness Rz: is used to compute splashed droplets ejection angle in Equation 16.270 in the *Fluent Theory Guide*.

  If you want to model splashing, you can specify **Number of Splash Drops**. A value of zero implies that the splashing model will not be used.

  The **Critical Temperature Factor** is used to determine the transition temperature (Equation 16.222 and Equation 16.250 in the *Fluent Theory Guide* for the `stanton-rutland` and `kuhnke` splashing models, respectively).

  Detailed information on the wall film model can be found in Wall-Film Model Theory in the *Fluent Theory Guide*.

  For a list of limitations that exist with `wall-film` boundary conditions, see Limitations on Using the Lagrangian Wall Film Model (p. 1240).

- `interior`

  This boundary condition means that the particles will pass through the internal boundary. This option is available only for internal boundary zones, such as a radiator or a porous jump.

It is also possible to use a user-defined function to compute the behavior of the particles at a physical boundary. More information about user-defined functions can be found in the Fluent Customization Manual.

Because you can stipulate any of these conditions at flow boundaries, it is possible to incorporate mixed discrete phase boundary conditions in your ANSYS Fluent model.

23.4.2. Default Discrete Phase Boundary Conditions

ANSYS Fluent makes the following assumptions regarding boundary conditions:

- The `reflect` type is assumed at wall, symmetry, and axis boundaries, with both coefficients of restitution equal to 1.0
- The `escape` type is assumed at all flow boundaries (pressure and velocity inlets, pressure outlets, and so on)
- The `interior` type is assumed at all internal boundaries (radiator, porous jump, and so on)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The coefficient of restitution can be modified only for wall boundaries.

23.4.3. Coefficients of Restitution

A normal or tangential coefficient of restitution equal to 1.0 implies that the particle retains all of its normal or tangential momentum after the rebound (an elastic collision). A normal or tangential coefficient of restitution equal to 0.0 implies that the particle retains none of its normal or tangential momentum after the rebound.

Nonconstant coefficients of restitution can be specified for wall zones with the `reflect` type boundary condition. The coefficients are set as a function of the impact angle, θ_1, in Particle Reflection at Wall in the *Fluent Theory Guide*.

Note that the default setting for both coefficients of restitution is a constant value of 1.0 (all normal and tangential momentum retained).

If you select the `reflect` type at a wall (only), you can define the **Normal** and **Tangent** coefficients of restitution under **Discrete Phase Reflection Coefficients**. You can select a `constant`, `polynomial`, `piecewise-linear`, or `piecewise-polynomial` function from the relevant drop-down lists. The dialog boxes for defining the polynomial, piecewise-linear, and piecewise-polynomial functions are the same as those used for defining temperature-dependent properties. The applied wall heat transfer model assumes that a liquid is getting in contact with the wall. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details.

23.4.4. Friction Coefficient

When at least one injection accounts for particle rotation (the **Enable Rotation** option is selected under the **Physical Models** tab in the **Set Injections Properties** dialog box), you can specify friction coefficients for wall zones with the `reflect` type boundary condition. In the **Wall** dialog box, under the **DPM** tab, you can define the **Friction Coefficient** as a `constant` or as a `polynomial`, `piecewise-linear`, or `piecewise-polynomial` function.

The default value for the `constant` is 0.2. For the piecewise-linear and piecewise-polynomial profiles, the friction coefficient is computed in terms of the relative tangential velocity. The default inputs for these functions are derived from the friction collision law (The Friction Collision Law in the *Fluent Theory Guide*) and are as follows.

- The `piecewise-linear` approximation is defined using the following default points for the relative (particle-to-wall) tangential velocity:
  - Point 1: 0 m/s
  - Point 2: 1 m/s
  - Point 3: 10 m/s
  - Point 4: 210 m/s

- The `piecewise-polynomial` approximation is defined in the three relative (particle-to-wall) tangential velocity ranges as follows:
  - Range 1: 0–1 m/s: a quadratic function
  - Range 2: 1–10 m/s: a constant
  - Range 3: 10–210 m/s: a linear function

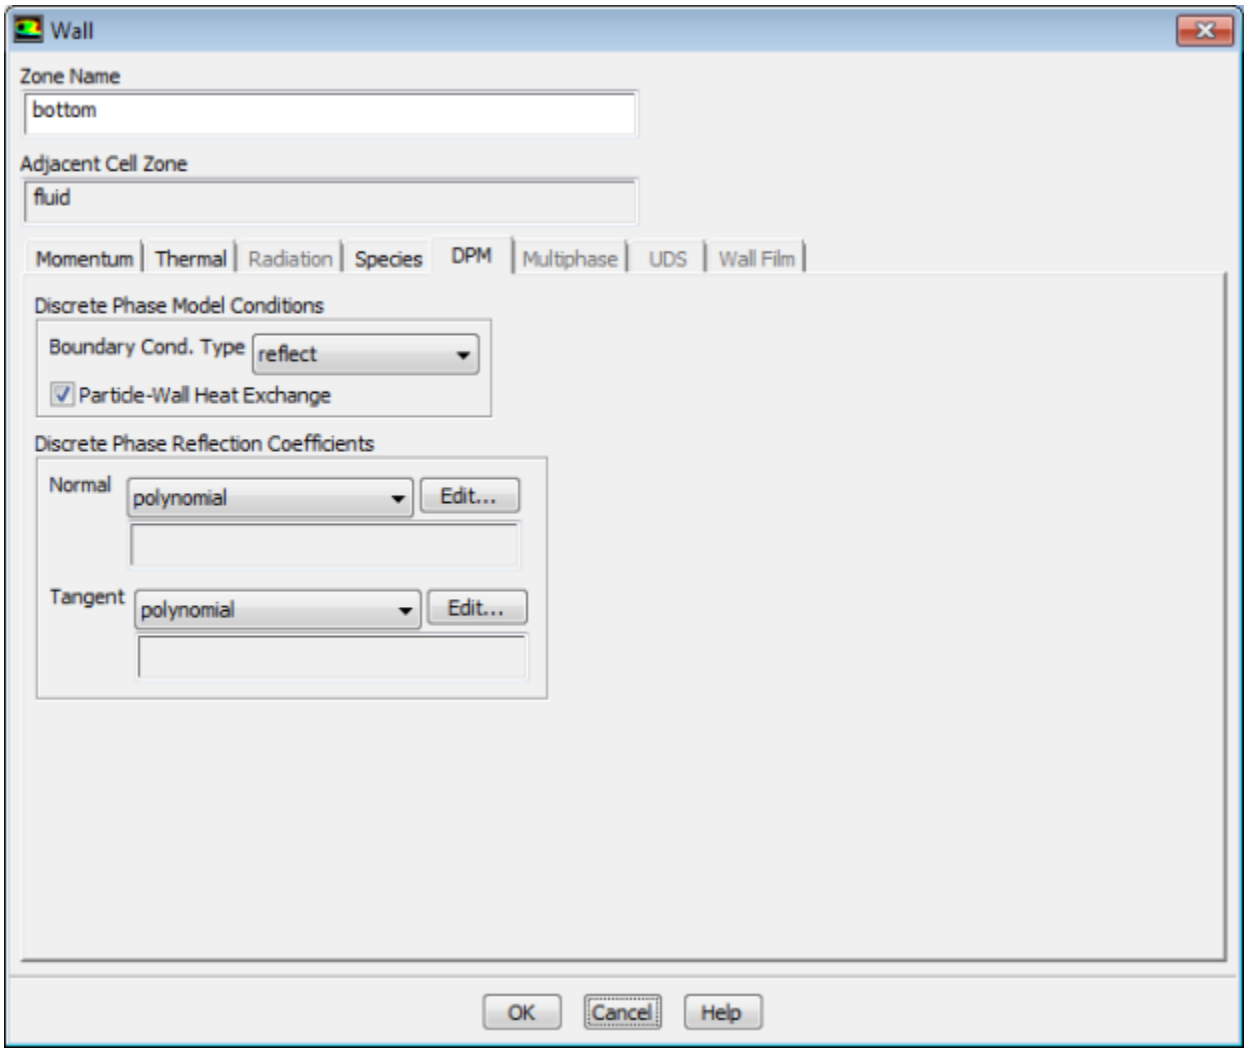
For details about using the **Piecewise-Linear Profile** dialog box and **Piecewise-Polynomial Profile** dialog box see Inputs for Piecewise-Linear Functions (p. 476) and Inputs for Piecewise-Polynomial Functions (p. 478), respectively.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.4.5. Particle-Wall Impingement Heat Transfer

To enable the particle-to-wall heat exchange for the `reflect`, `wall-jet`, or `wall-film` boundary conditions: In the **Wall** dialog box, under the **DPM** tab, enable the **Particle-Wall Heat Exchange** option. The option is available only for wall boundary conditions and unsteady particle tracking when the energy equation is enabled.

Figure 23.27: The Wall Dialog Box: the Particle-Wall Heat Exchange Option



Note that when a particle is reflected from a wall with the wall film DPM boundary condition, the particle-to-wall heat exchange is calculated directly between the particle and the wall. Any wall film present is not taken into account.

The model is applied for all inert, droplet, and multicomponent particles impinging on the wall. The specific model is not applied for the splashed particles. When the wall film DPM boundary condition is active, the model is applied in the Rebound Regime, and it is assumed that the particles hit the wall irrespective of the presence of a film. In the Splashing regime, the mass fraction that is deposited mixes with any existing film, and the splashed particles retain the impinging droplet temperature.

For combusting particles, the wall heat transfer is calculated only if the **Wet Combustion Model** option is enabled in the **Set Injection Properties** dialog box, and the particle liquid fraction is nonzero, otherwise the **Particle-Wall Heat Exchange** option has no effect.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Particle–Wall Impingement Heat Transfer Theory in the *Fluent Theory Guide* for the underlying theory and equations of the particle–wall impingement heat transfer model.

23.4.6. Film Condensation Model

Condensation can be defined as the transition from the gas phase to the liquid phase as a vapor condenses on a surface. The ANSYS Fluent film condensation model is triggered when the partial pressure of vapor species i in the bulk gas mixture exceeds either its vapor pressure at the wall-film or, in case no film exists, at the wall temperature. When these conditions are met, the vapor species will condense and form the liquid film on the wall faces.

The following limitations currently exist in the film condensation model:

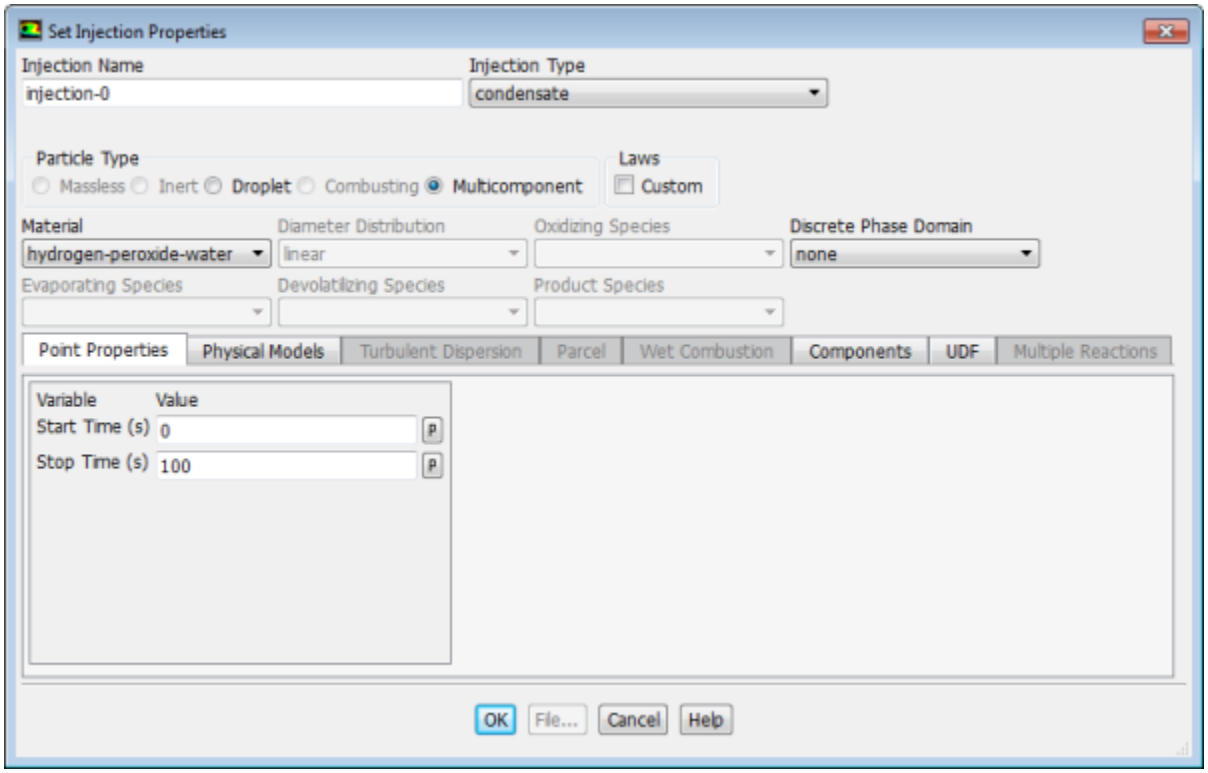
- The film particles are stagnant
- Only particles of a single material (droplet or multicomponent) can condense on a particular wall face
- At least one species in the mixture must be non-condensable

To use the film condensation model:

1. Enable the following models:
   - Energy equation
   - Species Transport model
   - **Unsteady Particle Tracking** (in the **Discrete Phase Model** dialog box)
2. If no droplet or multicomponent injection exists in the DPM case setup, create a condensate injection by selecting **condensate** from the **Injection Type** dropdown list in the **Set Injection Properties** dialog box and define the injection properties as appropriate.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.28: The Set Injection Properties Dialog Box: Condensate Injection



Note

A droplet or multicomponent injection must exist to define the vapor–liquid material pair for the condensation process.

For further information, see Injection Types (p. 1266), Point Properties for Condensate Injections (p. 1281), and Defining Injection Properties (p. 1286).

3. For each droplet and multicomponent injection, specify the condensable species by selecting the **Evaporating Species**.

4. In the **Wall** dialog box, under the **DPM** tab, select **wall-film** from the **Boundary Cond. Type** drop-down list and enable the **Film Condensation** option for each wall where condensation may occur. The Fluent solver automatically enables the **Wall Boundary Layer Model**. For more information, see Wall Boundary Layer Model (p. 1309).

Note

Film Condensation is available only with the **wall-film** DPM boundary condition.

5. Enable **Linearized Source Terms** in the **Numerics** tab of the **Discrete Phase Model** dialog box.

   Enabling the **Linearized Source Terms** option helps to stabilize the condensation solution and is strongly advisable.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the appropriate conditions exist, the evaporating species you have selected will condense on the walls that have the **Film Condensation** option enabled forming either droplet or multicomponent film particles (depending on the **Particle Type** selected in the **Set Injection Properties** dialog box).

For information about the theory behind the Film Condensation model, see Film Condensation in the *Fluent Theory Guide*.

23.4.7. Wall Boundary Layer Model

The Wall Boundary Layer model enables the boundary layer formulations for the mass and heat transfer equations for film vaporization and boiling as described in Film Vaporization and Boiling and Energy Transfer from the Film in the *Fluent Theory Guide*.

To enable the model, select **Wall Boundary Layer Model** in the **DPM** tab of the **Wall** dialog box. Note that the boundary layer formulations are always used for both condensation and vaporization rates when the Film Condensation model is enabled.

23.4.8. Setting Particle Erosion and Accretion Parameters

If the **Erosion/Accretion** option is selected in the **Physical Models** tab of the Discrete Phase Model Dialog Box (p. 2278) (see Monitoring Erosion/Accretion of Particles at Walls (p. 1251)), you can enable erosion models in the **DPM** tab of the Wall Dialog Box (p. 2456) and specify the corresponding erosion rate parameters at the walls.

Important

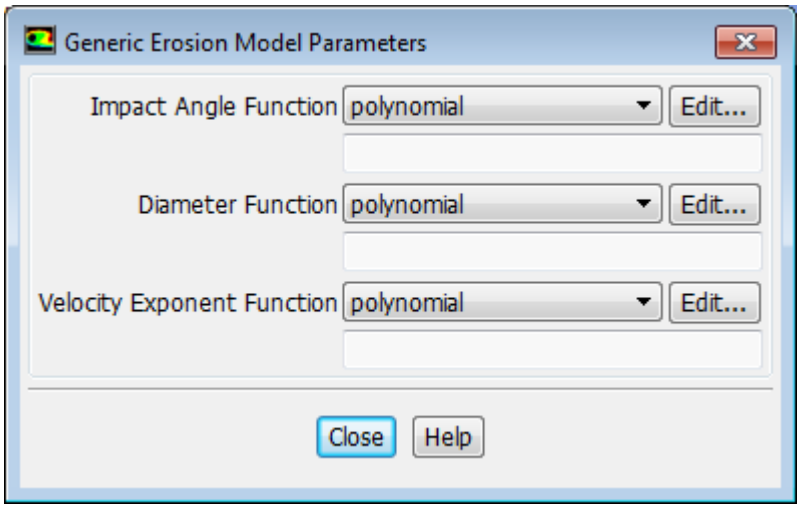
The default erosion rate parameters for each erosion model may not be appropriate for your analysis and must be adjusted based on your own experimental data.

The following models are available in ANSYS Fluent:

- **Generic Model**

  The erosion rate of the generic model is defined in Equation 16.308 in the Theory Guide as a product of the mass flux and specified functions for the particle diameter, impact angle, and velocity exponent. To specify the erosion parameters for the Generic model, click **Edit...** next to **Generic Model**.

Figure 23.29: TheGeneric Erosion Model Parameters Dialog Box



In the **Generic Erosion Model Parameters** dialog box, specify the following parameters using a `constant`, `polynomial`, `piecewise-linear`, or `piecewise-polynomial` function:

– **Impact Angle Function**: $f(\gamma)$ in Equation 16.308 in the *Fluent Theory Guide*.

– **Diameter Function**: $C(d_p)$ in Equation 16.308 in the *Fluent Theory Guide*.

– **Velocity Exponent Function**: $b(v)$ in Equation 16.308 in the *Fluent Theory Guide*.

See Accretion in the Theory Guide for a detailed description of these functions and Defining Properties Using Temperature-Dependent Functions (p. 475) for details about using the dialog boxes for defining polynomial, piecewise-linear, and piecewise-polynomial functions.

- **Finnie**

  To specify the erosion parameters for the Finnie model, click **Edit...** next to **Finnie**.

  Figure 23.30: TheFinnie Model Parameters Dialog Box

  
  In the **Finnie Model Parameters** dialog box, specify the following parameters:

  – **Model Constant, k**: k in Equation 16.301 in the *Fluent Theory Guide*.

  – **Velocity Exponent**: n in Equation 16.301 in the *Fluent Theory Guide*. The default value is 2. The value of the **Velocity Exponent** is generally within the range of 2.3 to 2.5 for metals.

  – **Angle of Maximum Erosion**: the impact angle between the approaching particle track and the wall at which the erosion reaches maximum.

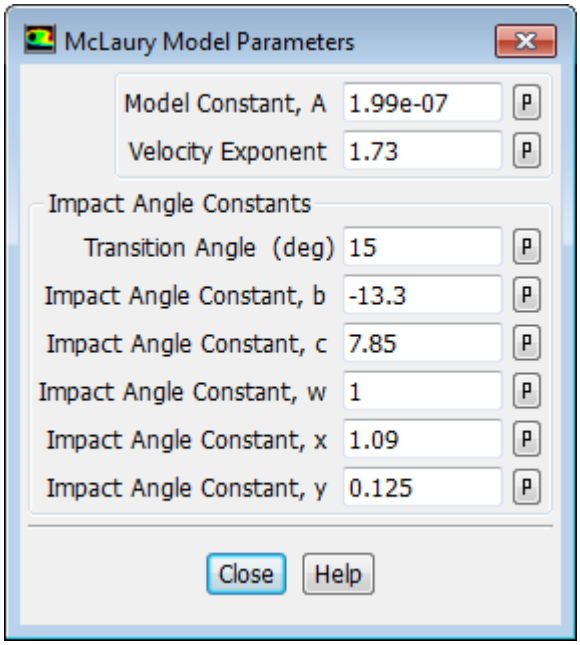
    For information about the theory behind the Finnie model, see Finnie Erosion Model in the *Fluent Theory Guide*.

- **McLaury**

  To specify the erosion parameters for the McLaury model, click **Edit...** next to **McLaury**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.31: TheMcLaury Model Parameters Dialog Box



In the **McLaury Model Parameters** dialog box, specify the following parameters:

– **Model Constant, A**: A in Equation 16.305 in the *Fluent Theory Guide*.

– **Velocity Exponent**: V in Equation 16.305 in the *Fluent Theory Guide*.

– **Transition Angle**: $\gamma_{\lim}$ in Equation 16.306 and Equation 16.307 in the *Fluent Theory Guide*.

– **Impact Angle Constant, b**: b in Equation 16.306 in the *Fluent Theory Guide*.

– **Impact Angle Constant, c**: c in Equation 16.306 in the *Fluent Theory Guide*.

– **Impact Angle Constant, w**: w in Equation 16.307 in the *Fluent Theory Guide*.

– **Impact Angle Constant, x**: x in Equation 16.307 in the *Fluent Theory Guide*.

– **Impact Angle Constant, y**: y in Equation 16.307 in the *Fluent Theory Guide*.

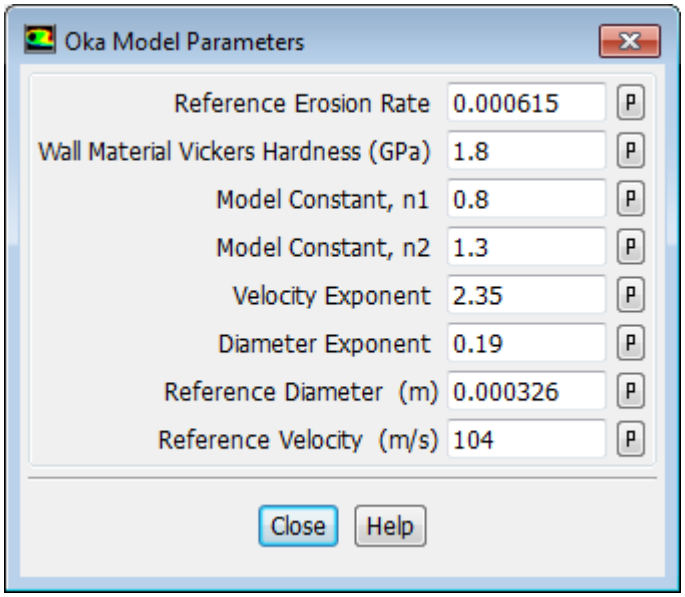
See Example of the McLaury Erosion Model Constants in the *Fluent Theory Guide* for more information about the McLaury model parameters. For theoretical background on the McLaury model, see McLaury Erosion Model in the *Fluent Theory Guide*.

- **Oka**

  To specify the erosion parameters for the Oka model, click **Edit...** next to **Oka**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.32: TheOka Model Parameters Dialog Box



In the **Oka Model Parameters** dialog box, specify the following parameters:

– **Reference Erosion Rate**: E_{90} in Equation 16.303 in the *Fluent Theory Guide*.

– **Wall Material Hardness**: H_v in Equation 16.304 in the *Fluent Theory Guide*.

– **Model Constant, n1**: n_1 in Equation 16.304 in the *Fluent Theory Guide*.

– **Model Constant, n2**: n_2 in Equation 16.304 in the *Fluent Theory Guide*.

– **Velocity Exponent**: k_2 in Equation 16.303 in the *Fluent Theory Guide*.

– **Diameter Exponent**: k_3 in Equation 16.303 in the *Fluent Theory Guide*.

– **Reference Diameter**: d_{ref} in Equation 16.303 in the *Fluent Theory Guide*.

– **Reference Velocity**: V_{ref} in Equation 16.303 in the *Fluent Theory Guide*.

See Example of the Oka Erosion Model Constants in the *Fluent Theory Guide* for an example of the Oka model parameters' values. For more information on the theory behind the Oka model, see Oka Erosion Model in the *Fluent Theory Guide*.

By default, all erosion models are enabled.

Important

- The default constants for the Finnie, Oka, and McLaury models have been tuned to match the experiment described by Oka [75] (p. 2891) in which 326-micron sand particles impact a carbon steel wall at a speed of 104 m/s and therefore are only valid for those specific conditions. You can use the default values as a starting point for your simulation and then adjust them as needed.
- Predictive capabilities of the erosion models are limited and strongly case dependent.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.5. Setting Material Properties for the Discrete Phase

In order to apply the physical models described in earlier sections to the prediction of the discrete phase trajectories and heat/mass transfer, ANSYS Fluent requires many physical property inputs.

For additional information, see the following sections:

23.5.1. Summary of Property Inputs
23.5.2. Setting Discrete-Phase Physical Properties

23.5.1. Summary of Property Inputs

Table 23.1: Property Inputs for Inert Particles (p. 1313) – Table 23.5: Property Inputs for Multicomponent Particles (Law 7) (p. 1315) summarize which of these property inputs are used for each particle type and in which of the equations for heat and mass transfer each property input is used. Detailed descriptions of each input are provided in Setting Discrete-Phase Physical Properties (p. 1316).

Table 23.1: Property Inputs for Inert Particles

Property	Symbol
density	ρ_p in Equation 16.1 in the Theory Guide
specific heat	c_p in Equation 16.92 and Equation 16.293
thermal conductivity	k_p in Equation 16.12 and k_l in Equation 16.294

23.5.2. Setting Discrete-Phase Physical Properties

23.5.2.1. The Concept of Discrete-Phase Materials

When you create a particle injection and define the initial conditions for the discrete phase (as described in Setting Initial Conditions for the Discrete Phase (p. 1265)), you choose a particular material as the particle's material. All particle streams of that material will have the same physical properties.

Important

Note that you will not choose a **Material** for a **Massless** particle type in the **Set Injections Properties** dialog box.

Discrete-phase materials are divided into four categories, corresponding to the four types of particles available. These material types are **inert-particle**, **droplet-particle**, **combusting-particle**, and **multicomponent-particle**. Each material type will be added to the **Material Type** list in the Create/Edit Materials Dialog Box (p. 2302) when an injection of that type of particle is defined (in the **Set Injection Properties** or **Set Multiple Injection Properties** dialog box, as described in Setting Initial Conditions for the Discrete Phase (p. 1265)). The first time you create an injection of each particle type, you will be able to choose a material from the database, and this will become the default material for that type of particle. That is, if you create another injection of the same type of particle, your selected material will be used for that injection as well. You may choose to modify the predefined properties for your selected particle material, if you want (as described in Modifying Properties of an Existing Material (p. 463)). If you need only one set of properties for each type of particle, you need not define any new materials; you can simply use the same material for all particles.

Important

If you do not find the material you want in the database, you can select a material that is close to the one you want to use, and then modify the properties and give the material a new name, as described in Creating a New Material (p. 466).

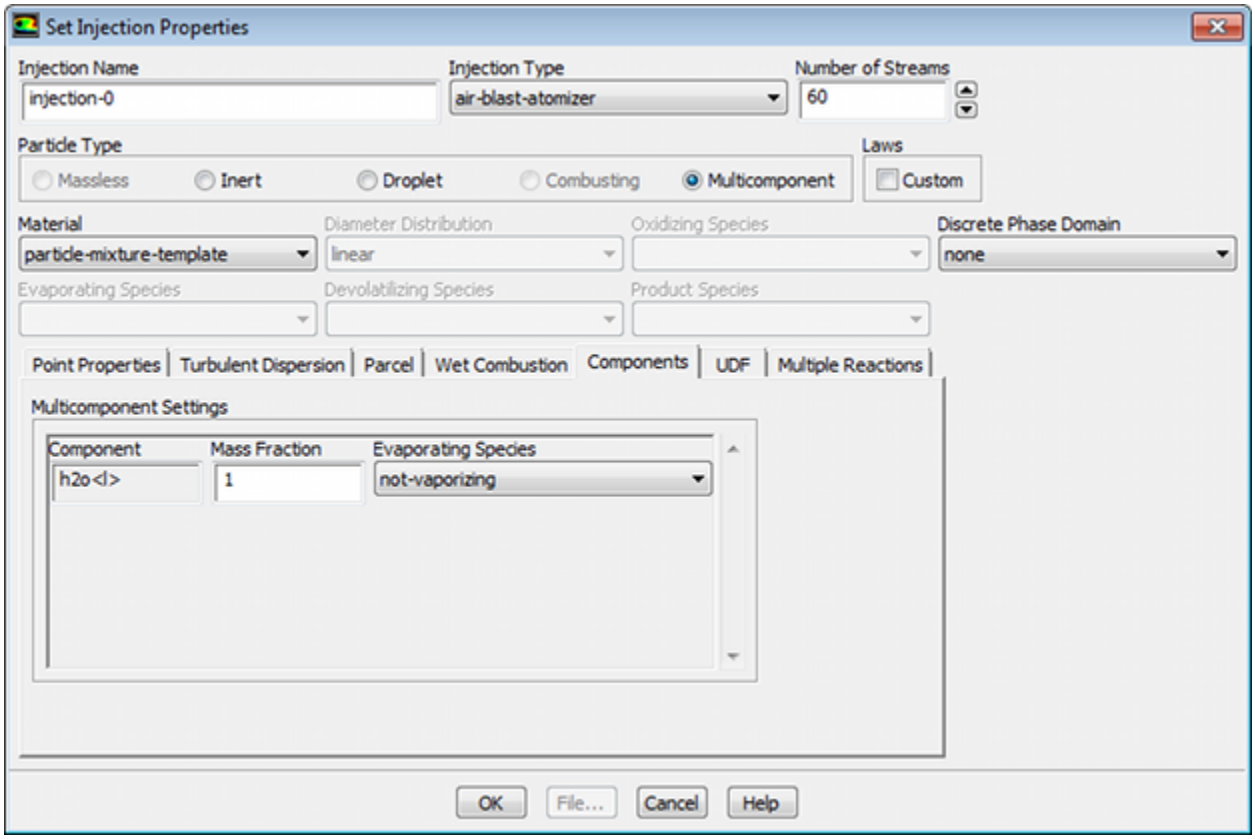
Important

Note that a discrete-phase material type will not appear in the **Material Type** list in the **Create/Edit Materials** dialog boxes until you have defined an injection of that type of particles. This means, for example, that you cannot define or modify any combusting-particle materials until you have defined a combusting particle injection (as described in Setting Initial Conditions for the Discrete Phase (p. 1265)).

For a **particle-mixture** material type, you must select the species in your mixture. To do this, click the **Edit...** button next to **Mixture Species** in the **Create/Edit Materials** dialog box. The **Species** dialog box will open, where you will include your **Selected Species**. The selected species will now be available in the **Set Injection Properties** dialog box, under the **Components** tab (Figure 23.33: The Components Tab (p. 1317)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.33: The Components Tab



23.5.2.1.1. Defining Additional Discrete-Phase Materials

In many cases, a single set of physical properties (density, heat capacity, and so on) is appropriate for each type of discrete phase particle considered in a given model. Sometimes, however, a single model may contain two different types of inert, droplet, combusting particles, or multicomponent particles (for example, heavy particles and gaseous bubbles or two different types of evaporating liquid droplets). In such cases, it is necessary to assign a different set of properties to the two (or more) different types of particles. This is easily accomplished by defining two or more inert, droplet, or combusting particle materials and using the appropriate one for each particle injection.

You can define additional discrete-phase materials either by copying them from the database or by creating them from scratch. See Using the **Create/Edit Materials** Dialog Box (p. 461) for instructions on using the Create/Edit Materials Dialog Box (p. 2302) to perform these actions.

Important

Recall that you must define at least one injection (as described in Setting Initial Conditions for the Discrete Phase (p. 1265)) containing particles of a certain type before you will be able to define additional materials for that particle type.

23.5.2.2. Description of the Properties

The properties that appear in the Create/Edit Materials Dialog Box (p. 2302) vary depending on the particle type (selected in the **Set Injection Properties** or **Set Multiple Injection Properties** dialog box, as described in Defining Injection Properties (p. 1286) and Defining Properties Common to More than One Injection (p. 1297)) and the physical models you are using in conjunction with the discrete-phase model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

All properties you may need to define for a discrete-phase material are listed below (alphabetically). See Table 23.1: Property Inputs for Inert Particles (p. 1313) – Table 23.4: Property Inputs for Combusting Particles (Law 5) (p. 1315) to see which properties are defined for each type of particle.

Binary Diffusivity

is the mass diffusion coefficient used in the vaporization law (Law 2), $D_{i,m}$ in Equation 16.104 and D_i in Equation 16.279 in the Theory Guide. This input is also used to define the mass diffusion of the oxidizing species to the surface of a combusting particle, $D_{i,m}$, as given in Equation 16.165 in the Theory Guide. (Note that the diffusion coefficient inputs that you supply for the continuous phase are not used for the discrete phase.)

For **Droplet Particle** type **Materials**, select **film-averaged** from the **Binary Diffusivity** drop-down list and specify parameters for the film-averaged model (see Equation 16.108 in the Theory Guide) using the **Film Binary Diffusivity** dialog box. The **film-averaged** model is recommended when accurate temperature-dependent binary diffusivity data are available.

To apply the unity Lewis number model (Equation 16.109 in the *Fluent Theory Guide*) select **unity-lewis-number** from the **Binary Diffusivity** drop-down. The unity Lewis number model is a simplified approach and is not appropriate when the molecular weights of the evaporating species (or oxidizing species for combusting particles) and the gas-phase mixture are very different. The model can be applied, for example, for the evaporation of water, light hydrocarbons, or methanol in air, but is not appropriate for heavy hydrocarbons.

You also have the option of implementing a user-defined function to model the particle binary diffusivity. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

To enable the pressure dependence for the binary diffusivity, in the **Create/Edit Materials** dialog box, under **Properties**, from the **Diffusivity Reference Pressure** drop-down list, select `constant` (see Equation 16.110 in the *Fluent Theory Guide*) and enter a value for the reference pressure P_{ref} that corresponds to the value defined for the **Binary Diffusivity** material property. The pressure dependence option is available with all property methods for the binary diffusivity, including `user-defined`, with the exception of the unity Lewis number model, for which the pressure dependence is already accounted for through the density variable in the model equation.

Boiling Point

is the temperature, T_{bp}, at which the calculation of the boiling rate equation (Equation 16.120 in the Theory Guide) is initiated by ANSYS Fluent. When a droplet particle reaches the boiling point, ANSYS Fluent applies Law 3 and assumes that the droplet temperature is constant at T_{bp}. The boiling point denotes the temperature at which the particle law transitions from the vaporization law to the boiling law.

For multicomponent particles the boiling point of the components is used only as a reference temperature of the latent heat. Instead, the boiling starts when the sum of the partial component saturation pressures reach the total fluid pressure. The definition of the saturation pressure curve is therefore essential for the boiling of multicomponent particles.

You also have the option of implementing a user-defined function to model the particle boiling point. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

Burnout Stoichiometric Ratio

is the stoichiometric requirement, S_b, for the burnout reaction, Equation 16.164 in the Theory Guide, in terms of mass of oxidant per mass of char in the particle.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Combustible Fraction

is the mass fraction of char, f_{comb}, in the coal particle, that is, the fraction of the initial combusting particle that will react in the surface reaction, Law 5 (Equation 16.163 in the Theory Guide).

Combustion Model

defines which version of the surface char combustion law (Law5) is being used. If you want to use the default diffusion-limited rate model, retain the selection of **diffusion-limited** in the drop-down list to the right of **Combustion Model**. No additional inputs are necessary, because the binary diffusivity defined above will be used in Equation 16.165 in the Theory Guide.

To use the kinetics/diffusion-limited rate model for the surface combustion model, select **kinetics/diffusion-limited** in the drop-down list. The Kinetics/Diffusion-Limited Combustion Model Dialog Box (p. 2352) will appear and you will enter the **Mass Diffusion Limited Rate Constant** (C_1 in Equation 16.166 in the Theory Guide), **Kinetics Limited Rate Pre-exponential Factor** (C_2 in Equation 16.167), and **Kinetics Limited Rate Activation Energy** (E in Equation 16.167).

Note that the **Kinetics/Diffusion-Limited Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.

To use the intrinsic model for the surface combustion model, select **intrinsic-model** in the drop-down list. The Intrinsic Combustion Model Dialog Box (p. 2353) will appear and you will enter the **Mass Diffusion Limited Rate Constant** (C_1 in Equation 16.166 in the Theory Guide), **Kinetics Limited Rate Pre-exponential Factor** (A_i in Equation 16.176), **Kinetics Limited Rate Activation Energy** (E_i in Equation 16.176), **Char Porosity** (θ in Equation 16.173), **Mean Pore Radius** ($\overline{r}_p$ in Equation 16.175), **Specific Internal Surface Area** (A_g in Equation 16.170 Equation 16.172), **Tortuosity** (τ in Equation 16.173), and **Burning Mode, alpha** (α in Equation 16.177).

Note that the **Intrinsic Combustion Model** dialog box is a modal dialog box, which means that you must tend to it immediately before continuing the property definitions.

To use the multiple surface reactions model, select **multiple-surface-reactions** in the drop-down list. ANSYS Fluent will display the Multiple Surface Reactions Dialog Box (p. 2354) informing you to open the **Reactions** dialog box, where you can review or modify the particle surface reactions that you specified as described in Overview of User Inputs for Modeling Species Transport and Reactions (p. 958). In addition, you can set property options for the char specific heat and density:

Composition Dependent Specific Heat

if this option is enabled, your input for the particle c_p property will be used to determine the specific heat of the volatiles and ash component. The specific heat of the char will be calculated as a mass-weighted average of the particle specific heat values, and the particle specific heat is finally calculated as the mass average of the char and volatiles+ash fractions. The specific heat of the particle surface species should be defined in the corresponding fluid materials of the Mixture material.

Composition Dependent Density

if this option is enabled, your input for the particle Density property will be used to determine the density of the volatiles and ash component. The density of the char will be calculated as a volume-weighted average value of the particle surface species densities, and the particle density is finally calculated as the volume-weighted average of the char and volatiles+ash fractions. The

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

density of the particle surface species should be defined in the corresponding fluid materials of the Mixture material.

Important

If you have not yet defined any particle surface reactions, you must be sure to define them now. See Using the Multiple Surface Reactions Model for Discrete-Phase Particle Combustion (p. 1002) for more information about using the multiple surface reactions model.

You will notice that the **Burnout Stoichiometric Ratio** and **Heat of Reaction for Burnout** are no longer available in the **Create/Edit Materials** dialog box, as these parameters are now computed from the particle surface reactions you defined in the **Reactions** dialog box.

Note that the multiple surface reactions model is available only if the **Particle Surface** option for **Reactions** is enabled in the **Species Model** dialog box. See User Inputs for Particle Surface Reactions (p. 1001) for details.

Composition Averaging Coefficient,

is the coefficient α_Y in Equation 16.201 in the *Fluent Theory Guide*. To assume bulk gas composition for the physical properties in the particle vaporization and heating rates equations, select `none` from the **Composition Averaging Coefficient** drop-down in the **Create/Edit Materials** dialog box, under **Properties**. To enable property averaging, select `constant` and enter a value between 0 and 1 for the **Composition Averaging Coefficient**. $\alpha_Y = 1$ corresponds to bulk gas mixture. For $\alpha_Y = 0$, the composition reverts to the particle surface composition.

Important

When you define the **Composition Averaging Coefficient** with a `constant` value other than 1, you must also specify **Specific Heat**, **Viscosity** and **Thermal Conductivity** for the evaporating species (in the **Create/Edit Materials** dialog box, under **Properties**, for the corresponding fluid material of the continuous phase mixture). Note that for the definition of the evaporating species properties, the **user-defined** method is not supported and should not be used.

The default and recommended value for the averaging coefficient is 1/3. However, to improve the simulation results, you must provide accurate temperature-dependent data for the vapor material (through the **Create/Edit Materials** dialog box).

Cp

is the specific heat, c_p, of the particle. The specific heat may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Cp**. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties. For multicomponent particles, it can be calculated as a mass-weighted value of the specific heat of the droplet component.

You also have the option of implementing a user-defined function to model the particle specific heat. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

A composition-dependent char specific heat option can be enabled if you are using the multiple-surface-reactions model for a combusting particle. For details on enabling this model, see **Combustion Model** (p. 1319).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you are using the non-premixed or the partially-premixed combustion model in the continuous phase calculation, the specific heat defined for the particle material will be used for the specific heat and enthalpy calculations of the non-volatile/non-reacting particle mass.

Density

is the density of the particulate phase in units of mass per unit volume of the discrete phase. This density is the mass density and not the volumetric density. The density may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Density**. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties. For compressible flows, or if any of the real-gas models is enabled, the **compressible-liquid** method is also available. See Compressible Liquid Density Method (p. 480) for details. For multicomponent particles, it can be calculated as a volume-weighted value of the density of the droplet components.

You also have the option of implementing a user-defined function to model the particle density. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

For a combusting particle that swells during the trajectory calculations, the temperature-dependent density calculation is suspended during the devolatilization law and your input is used to determine the initial particle diameter, $d_{p,0}$ at the start of the devolatilization in Equation 16.157 in the *Fluent Theory Guide*. A composition-dependent char density option can be enabled if you are using the multiple-surface-reactions model for a combusting particle. For details on enabling this model, see **Combustion Model** (p. 1319).

Devolatilization Model

defines which version of the devolatilization model, Law 4, is being used. If you want to use the default constant rate devolatilization model, Equation 16.126 in the Theory Guide, retain the selection of **constant** in the drop-down list to the right of **Devolatilization Model** and input the rate constant A_0 in the field below the list.

You can choose one of the optional devolatilization models (the single kinetic rate, two kinetic rates, or CPD model, as described in Devolatilization (Law 4) in the Theory Guide) by selecting **single rate**, **two-competing-rates**, or **cpd-model** in the drop-down list.

When the single kinetic rate model (**single-rate**) is selected, the Single Rate Devolatilization Dialog Box (p. 2350) will appear and you will enter the **Pre-exponential Factor**, A_1, and the **Activation Energy**, E, to be used in Equation 16.128 in the Theory Guide for the computation of the kinetic rate.

When the two competing rates model (**two-competing-rates**) is selected, the Two Competing Rates Model Dialog Box (p. 2351) will appear and you will enter, for the **First Rate** and the **Second Rate**, the **Pre-exponential Factor** (A_1 in Equation 16.130 and A_2 in Equation 16.131 in the Theory Guide), **Activation Energy** (E_1 in Equation 16.130 and E_2 in Equation 16.131), and **Weighting Factor** (α_1 and α_2 in Equation 16.132). The constants you specify are used in Equation 16.130 through Equation 16.132.

When the CPD model (**cpd-model**) is selected, the **CPD Model** dialog box will appear and you will enter the **Initial Fraction of Bridges in Coal Lattice** (p_0 in Equation 16.143 of the Theory Guide), **Initial Fraction of Char Bridges** (c_0 in Equation 16.142), **Lattice Coordination Number** ($\sigma+1$ in Equation 16.154), **Cluster Molecular Weight** ($M_{w,1}$ in Equation 16.154), and **Side Chain Molecular Weight** ($M_{w,\delta}$ in Equation 16.153).

Note that the **Single Rate Devolatilization Model**, **Two Competing Rates Model**, and **CPD Model** dialog boxes are modal dialog boxes, which means that you must tend to them immediately before continuing the property definitions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Diffusivity Reference Pressure

is the reference pressure P_{ref} for the pressure dependent binary diffusivity in Equation 16.110 in the *Fluent Theory Guide*. To apply the pressure dependence, in the **Create/Edit Materials** dialog box, under **Properties**, from the **Diffusivity Reference Pressure** drop-down list, select `constant` and enter a reference pressure value corresponding to the value for the **Binary Diffusivity** material property. If `none` is selected from the **Diffusivity Reference Pressure** drop-down list, ANSYS Fluent assumes no pressure dependence for the binary diffusivity.

Heat of Pyrolysis

is the heat of the instantaneous pyrolysis reaction , h_{pyrol}, that the evaporating/boiling species may undergo when released to the continuous phase. This input represents the conversion of the evaporating species to lighter components during the evaporation process. The heat of pyrolysis should be specified as a positive number for exothermic reaction and as a negative number for endothermic reaction. The default value of zero implies that the heat of pyrolysis is not considered. This input is used in Equation 16.436 in the Theory Guide.

Heat of Reaction for Burnout

is the heat released by the surface char combustion reaction, Law 5 (Equation 16.164 in the Theory Guide). This parameter is specified in terms of heat release (for example, Joules) per unit mass of char consumed in the surface reaction.

Latent Heat

is the latent heat of vaporization, h_{fg}, required for phase change from an evaporating liquid droplet (Equation 16.112, Equation 16.285, Equation 16.286, and Equation 16.300 in the Theory Guide) or for the evolution of volatiles from a combusting particle (Equation 16.158 in the Theory Guide). This input is supplied in units of J/kg in SI units or of Btu/lb_m in British units and is treated as a constant by ANSYS Fluent. For the droplet particle, the latent heat value at the boiling point temperature should be used.

You also have the option of implementing a user-defined function to model the particle latent heat. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

React. Heat Fraction Absorbed by Solid

is the parameter f_h (Equation 16.178 in the Theory Guide), which controls the distribution of the heat of reaction between the particle and the continuous phase. The default value of zero implies that the entire heat of reaction is released to the continuous phase.

Saturation Vapor Pressure

is the saturated vapor pressure, p_{sat}, defined as a function of temperature, which is used in the vaporization law, Law 2 (Equation 16.102 in the Theory Guide). The saturated vapor pressure may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of its name. (See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties.) In the case of unrealistic inputs, ANSYS Fluent restricts the range of P_{sat} to between 0.0 and the operating pressure. Correct specification of a realistic vapor pressure curve is essential for accurate results from the vaporization model.

You also have the option of implementing a user-defined function to model the particle saturation vapor pressure. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

Swelling Coefficient

is the coefficient C_{sw} in Equation 16.157 in the Theory Guide, which governs the swelling of the coal particle during the devolatilization law, Law 4 (Devolatilization (Law 4) in the Theory Guide). A swelling coefficient

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of unity (the default) implies that the coal particle stays at constant diameter during the devolatilization process.

You also have the option of implementing a user-defined function to model the particle swelling coefficient. See DEFINE_DPM_PROPERTY in the *Fluent Customization Manual* for more information.

Thermal Conductivity

is the thermal conductivity of the particle, k_p. This input is specified in units of W/m-K in SI units or $^{\text{Btu}}/_{\text{ft-h-}^0\text{F}}$ in British units and is treated as a constant by ANSYS Fluent.

Temperature Averaging Coefficient,

is the coefficient α_T in Equation 16.200 in the *Fluent Theory Guide*. To assume bulk gas temperature for the physical properties in the particle vaporization and heating rates equations, select none from the **Temperature Averaging Coefficient** drop-down in the **Create/Edit Materials** dialog box, under **Properties**. To enable property averaging, select constant and enter a value between 0 and 1 for the **Temperature Averaging Coefficient**. α_T= 1 corresponds to bulk gas conditions. For α_T= 0, the temperature reverts to the particle surface temperature.

Important

When you define the **Temperature Averaging Coefficient** with a constant value other than 1, you must also define **Specific Heat**, **Viscosity** and **Thermal Conductivity** for the evaporating species (in the **Create/Edit Materials** dialog box, under **Properties**, for the corresponding fluid material of the continuous phase mixture). Note that for the definition of the evaporating species properties, the **user-defined** method is not supported and should not be used.

The default and recommended value for the averaging coefficient is 1/3. However, to improve the simulation results, you must provide accurate temperature-dependent data for the evaporating vapor material (through the **Create/Edit Materials** dialog box).

Thermophoretic Coefficient

is the coefficient $D_{T,p}$ in Equation 16.11 in the Theory Guide, and appears when the thermophoretic force (which is described in Thermophoretic Force in the Theory Guide) is included in the trajectory calculation (that is, when the **Thermophoretic Force** option is enabled in the **Discrete Phase Model** dialog box). The default is the expression developed by Talbot [117] (p. 2893) (**talbot-diffusion-coeff**) and requires no input from you. You can also define the thermophoretic coefficient as a function of temperature by selecting one of the function types from the drop-down list to the right of **Thermophoretic Coefficient**. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties.

You also have the option of implementing a user-defined function to model the particle thermophoretic coefficient. See DEFINE_DPM_PROPERTY in the *Fluent Customization Manual* for more information.

Vaporization Temperature

is the temperature, T_{vap}, at which the calculation of vaporization from a liquid droplet or devolatilization from a combusting particle is initiated by ANSYS Fluent. Until the particle temperature reaches T_{vap}, the particle is heated via Law 1, Equation 16.92 in the Theory Guide. This temperature input represents a modeling decision rather than any physical characteristic of the discrete phase.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You also have the option of implementing a user-defined function to model the particle vaporization temperature. See DEFINE_DPM_PROPERTY in the *Fluent Customization Manual* for more information.

Vapor-Particle-Equilibrium

is the selected approach for the calculation of the vapor concentration of the components at the surface. This can be Raoult's law (Equation 16.191 in the Theory Guide), the Peng-Robinson real gas model (Equation 16.199 in the Theory Guide), or a user-defined function that defines the equilibrium.

Vaporization Model

defines which vaporization model is used for pure droplets (Law 2) and for multicomponent droplets (Law 7). If you want to use the default diffusion controlled model, retain the selection of **diffusion-controlled** from the drop-down list to the right of **Vaporization Model**. This will apply Equation 16.101 in the Theory Guide.

To use the convection/diffusion controlled model for vaporization select **convection/diffusion-controlled** from the drop-down list. Equation 16.106 in the Theory Guide will be applied for the calculation of the vaporization rate, and Equation 16.116 in the Theory Guide will be applied in the particle heat transfer calculations This model is recommended when evaporation rates are high. For slowly evaporating droplets both models are expected to give similar results.

If you have selected the **convection/diffusion-controlled**, you can enable the **Variable Lewis Number Formulation** option in the **Convection/Diffusion Model** dialog box to compute the Spalding heat number from Equation 16.115 in the *Fluent Theory Guide*. If the option is disabled ANSYS Fluent uses Equation 16.116.

You can also enable averaging of the Spalding heat transfer term for the convection/diffusion-controlled model according to Equation 16.117 in the *Fluent Theory Guide* by using the TUI command `define/models/dpm/options/vaporization-heat-transfer-averaging`. This option has the net effect of increasing the heat-transfer to the droplet and may produce more realistic results for cases with large temperature differences between droplet and bulk gas.

Volatile Component Fraction

(f_{v0}) is the mass fraction of a droplet particle that may vaporize via Laws 2 and/or 3 (Droplet Vaporization (Law 2) in the Theory Guide). For combusting particles, it is the mass fraction of volatiles that may be evolved via Law 4 (Devolatilization (Law 4) in the Theory Guide).

When the effect of particles on radiation is enabled (for the P-1 or discrete ordinates radiation model only) in the Discrete Phase Model Dialog Box (p. 2278), you must define the following additional parameters:

Particle Emissivity

is the emissivity of particles in your model, ε_p, used to compute radiation heat transfer to the particles (Equation 16.92, Equation 16.112, Equation 16.123, Equation 16.158, and Equation 16.178 in the Theory Guide) when the P-1 or discrete ordinates radiation model is active. Note that you must enable radiation to particles, using the **Particle Radiation Interaction** option in the Discrete Phase Model Dialog Box (p. 2278). Recommended values of particle emissivity are 1.0 for coal particles and 0.5 for ash [62] (p. 2890).

You also have the option of implementing a user-defined function to model the particle emissivity. See DEFINE_DPM_PROPERTY in the *Fluent Customization Manual* for more information.

Particle Scattering Factor

is the scattering factor, f_p, due to particles in the P-1 or discrete ordinates radiation model (Equation 5.34 in the Theory Guide). Note that you must enable particle effects in the radiation model, using the **Particle Radiation Interaction** option in the Discrete Phase Model Dialog Box (p. 2278). The recommended value of

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

f_p for coal combustion modeling is 0.9 [62] (p. 2890). Note that if the effect of particles on radiation is enabled, scattering in the continuous phase will be ignored in the radiation model.

You also have the option of implementing a user-defined function to model the particle scattering factor. See `DEFINE_DPM_PROPERTY` in the *Fluent Customization Manual* for more information.

When an atomizer injection model and/or the droplet breakup or collision model is enabled in the Set Injection Properties Dialog Box (p. 2796) (atomizers) and/or Discrete Phase Model Dialog Box (p. 2278) (droplet breakup/collision), you must define the following additional parameters:

Droplet Surface Tension

is the droplet surface tension, σ. The surface tension may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Droplet Surface Tension**. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties. You also have the option of implementing a user-defined function to model the droplet surface tension. More information about user-defined functions can be found in the Fluent Customization Manual.

Viscosity

is the droplet viscosity, μ_l. The viscosity may be defined as a function of temperature by selecting one of the function types from the drop-down list to the right of **Viscosity**. See Defining Properties Using Temperature-Dependent Functions (p. 475) for details about temperature-dependent properties. You also have the option of implementing a user-defined function to model the droplet viscosity. More information about user-defined functions can be found in the Fluent Customization Manual.

23.6. Solution Strategies for the Discrete Phase

Solution of the discrete phase implies integration in time of the force balance on the particle (Equation 16.1 in the Theory Guide) to yield the particle trajectory. As the particle is moved along its trajectory, heat and mass transfer between the particle and the continuous phase are also computed via the heat/mass transfer laws (Laws for Heat and Mass Exchange in the Theory Guide). The accuracy of the discrete phase calculation therefore depends on the time accuracy of the integration and upon the appropriate coupling between the discrete and continuous phases when required. Numerical controls are described in Numerics of the Discrete Phase Model (p. 1260). Coupling and performing trajectory calculations are described in Performing Trajectory Calculations (p. 1325). Resetting the Interphase Exchange Terms (p. 1329) and Parallel Processing for the Discrete Phase Model (p. 1360) provide information about resetting interphase exchange terms and using the parallel solver for a discrete phase calculation.

For additional information, see the following sections:

23.6.1. Performing Trajectory Calculations
23.6.2. Resetting the Interphase Exchange Terms

23.6.1. Performing Trajectory Calculations

The trajectories of your discrete phase injections are computed when you display the trajectories using graphics or when you perform solution iterations. That is, you can display trajectories without impacting the continuous phase, or you can include their effect on the continuum (termed a coupled calculation). In turbulent flows, trajectories can be based on mean (time-averaged) continuous phase velocities or they can be impacted by instantaneous velocity fluctuations in the fluid. This section describes the procedures and commands you use to perform coupled or uncoupled trajectory calculations, with or without stochastic tracking or cloud tracking.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.6.1.1. Uncoupled Calculations

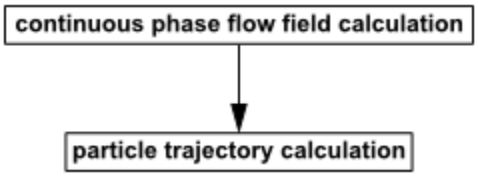
For the uncoupled calculation, you will perform the following two steps:

1. Solve the continuous phase flow field.

2. Plot (and report) the particle trajectories for discrete phase injections of interest.

In the uncoupled approach, this two-step procedure completes the modeling effort, as illustrated in Figure 23.34: Uncoupled Discrete Phase Calculations (p. 1326). The particle trajectories are computed as they are displayed, based on a fixed continuous-phase flow field. Graphical and reporting options are detailed in Postprocessing for the Discrete Phase (p. 1329).

Figure 23.34: Uncoupled Discrete Phase Calculations



This procedure is adequate when the discrete phase is present at a low mass and momentum loading, in which case the continuous phase is not impacted by the presence of the discrete phase.

23.6.1.2. Coupled Calculations

In a coupled two-phase simulation, ANSYS Fluent modifies the two-step procedure above as follows:

1. Solve the continuous phase flow field (prior to introduction of the discrete phase).

2. Introduce the discrete phase by calculating the particle trajectories for each discrete phase injection.

3. Recalculate the continuous phase flow, using the interphase exchange of momentum, heat, and mass determined during the previous particle calculation.

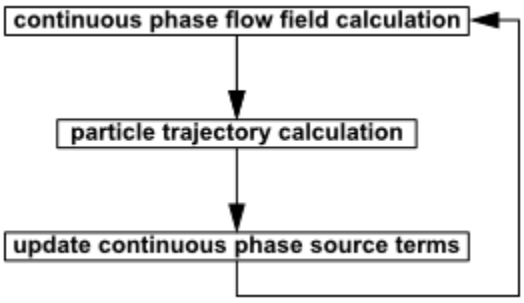
4. Recalculate the discrete phase trajectories in the modified continuous phase flow field.

5. Repeat the previous two steps until a converged solution is achieved in which both the continuous phase flow field and the discrete phase particle trajectories are unchanged with each additional calculation.

This coupled calculation procedure is illustrated in Figure 23.35: Coupled Discrete Phase Calculations (p. 1327). When your ANSYS Fluent model includes a high mass and/or momentum loading in the discrete phase, the coupled procedure must be followed in order to include the important impact of the discrete phase on the continuous phase flow field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.35: Coupled Discrete Phase Calculations



Important

When you perform coupled calculations, all defined discrete phase injections will be computed. You cannot calculate a subset of the injections you have defined. If there are massless particle injections defined, these will have no effect in the coupled calculation.

23.6.1.2.1. Procedures for a Coupled Two-Phase Flow

If your ANSYS Fluent model includes prediction of a coupled two-phase flow, you should begin with a partially (or fully) converged continuous-phase flow field. You will then create your injection(s) and set up the coupled calculation.

For each discrete-phase iteration, ANSYS Fluent computes the particle/droplet trajectories and updates the interphase exchange of momentum, heat, and mass in each control volume. These interphase exchange terms then impact the continuous phase when the continuous phase iteration is performed. During the coupled calculation, ANSYS Fluent will perform the discrete phase iteration at specified intervals during the continuous-phase calculation. The coupled calculation continues until the continuous phase flow field no longer changes with further calculations (that is, all convergence criteria are satisfied). When convergence is reached, the discrete phase trajectories no longer change either, since changes in the discrete phase trajectories would result in changes in the continuous phase flow field.

The steps for setting up the coupled calculation are as follows:

1. Solve the continuous phase flow field.

2. In the Discrete Phase Model Dialog Box (p. 2278) (Figure 23.1: The Discrete Phase Model Dialog Box and the Tracking Parameters (p. 1247)), enable the **Interaction with Continuous Phase** option.

3. Set the frequency with which the particle trajectory calculations are introduced in the **DPM Iteration Interval** field. If you set this parameter to 5, for example, a discrete phase iteration will be performed every fifth continuous phase iteration. The optimum number of iterations between trajectory calculations depends upon the physics of your ANSYS Fluent model.

   Important

   Note that if you set this parameter to 0, ANSYS Fluent will not perform any discrete phase iterations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

During the coupled calculation (which you initiate using the Run Calculation Task Page (p. 2537) in the usual manner) you will see the following information in the ANSYS Fluent console as the continuous and discrete phase iterations are performed:

```
 iter   continuity   x-velocity   y-velocity       k         epsilon       energy    time/it

```

Note that you can perform a discrete phase calculation at any time by using the `solve/dpm-update` text command.

23.6.1.2.2. Stochastic Tracking in Coupled Calculations

If you include the stochastic prediction of turbulent dispersion in the coupled two-phase flow calculations, the number of stochastic tries applied each time the discrete phase trajectories are introduced during coupled calculations will be equal to the **Number of Tries** specified in the Set Injection Properties Dialog Box (p. 2796). For transient particle tracking, the number of tries is set to 1. Input of this parameter is described in Stochastic Tracking (p. 1294). An input of $n \geq 1$ requests n stochastic trajectory calculations for each particle in the injection. When the number of stochastic tracks included is small, you may find that the ensemble average of the trajectories is quite different each time the trajectories are computed. These differences may, in turn, impact the convergence of your coupled solution. For good convergence of a coupled solution, a statistical independent distribution of tracks can be achieved with an adequate number of stochastic tracks and/or a sufficient number of different starting locations of the tracks.

23.6.1.2.3. Under-Relaxation of the Interphase Exchange Terms

When you are coupling the discrete and continuous phases using the calculation procedures noted above, ANSYS Fluent applies under-relaxation to the momentum, heat, and mass transfer terms. This under-relaxation serves to increase the stability of the coupled calculation procedure by letting the impact of the discrete phase change only gradually:

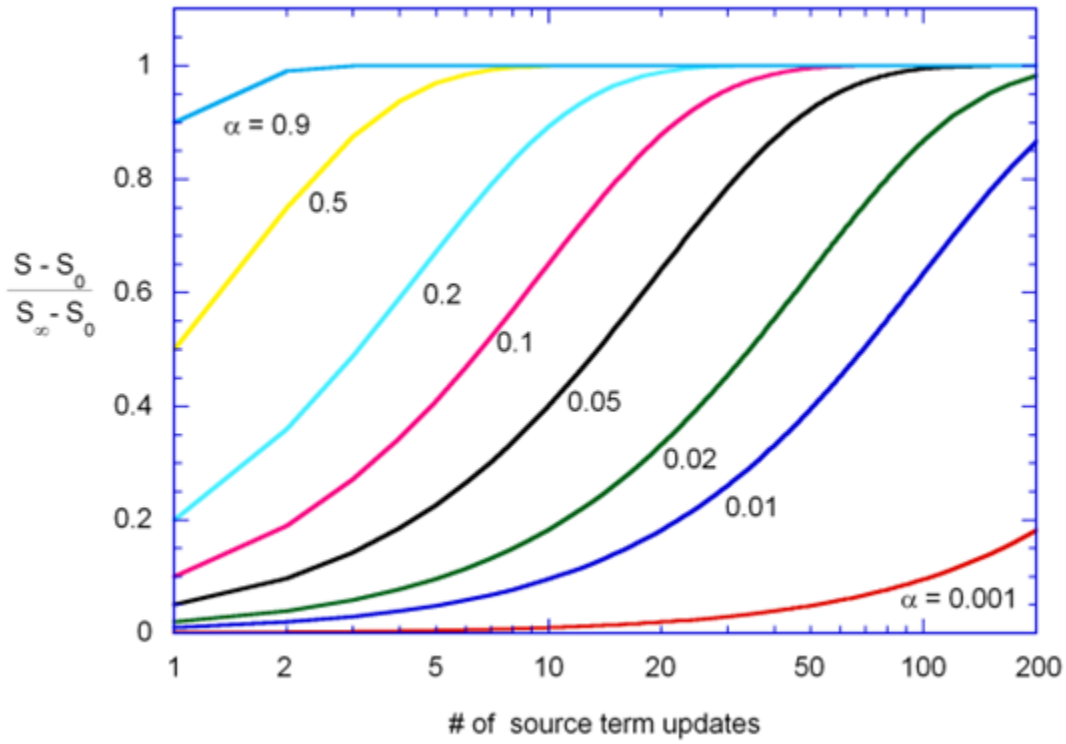
$$E_{new} = E_{old} + \alpha \left(E_{calculated} - E_{old} \right) \tag{23.13}$$

where E_{new} is the exchange term, E_{old} is the previous value, $E_{calculated}$ is the newly computed value, and α is the particle/droplet under-relaxation factor. For α, ANSYS Fluent uses a default value of 0.5 for all types of analysis except transient flows with unsteady particle tracking, in which case the default value of 0.9 is used. You can modify α by changing the value in the **Discrete Phase Sources** field under **Under-Relaxation Factors** in the **Solution Controls** task page. You may need to decrease α in order to improve the stability of coupled discrete phase calculations.

Figure 23.36: Effect of Number of Source Term Updates on Source Term Applied to Flow Equations (p. 1329) shows how the source term, S, when applied to the flow equations, changes with the number of updates for varying under-relaxation factors. In Figure 23.36: Effect of Number of Source Term Updates on Source Term Applied to Flow Equations (p. 1329), S_∞ is the final source term for which a value is reached after a certain number of updates and S_0 is the initial source term at the start of the computation. The value of S_0 is typically zero at the beginning of the calculation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.36: Effect of Number of Source Term Updates on Source Term Applied to Flow Equations



In a continuous flow simulation, with continuous DPM tracking, suppose that the DPM under-relaxation factor is chosen to be 0.5, with 20 continuous phase iterations per DPM iteration. From Figure 23.36: Effect of Number of Source Term Updates on Source Term Applied to Flow Equations (p. 1329), we see that approximately 10 source term updates are required for the DPM sources to reach their final values. Therefore, in this example, at least 200 continuous phase iterations are required after any change to the DPM sources (for example, a new injection or a changed DPM mass flow rate), to ensure that the change has taken effect.

23.6.2. Resetting the Interphase Exchange Terms

If you have performed coupled calculations, resulting in nonzero interphase sources/sinks of momentum, heat, and/or mass that you do not want to include in subsequent calculations, you can reset these sources to zero.

Solution → Initialization → Reset DPM Sources

When you select **Reset DPM Sources**, the sources will immediately be reset to zero without any further confirmation from you.

23.7. Postprocessing for the Discrete Phase

After you have completed your discrete phase inputs and any coupled two-phase calculations of interest, you can display and store the particle trajectory predictions. ANSYS Fluent provides both graphical and alphanumeric reporting facilities for the discrete phase, including the following:

- graphical display of the particle trajectories

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- summary reports of trajectory fates
- step-by-step reports of the particle position, velocity, temperature, and diameter
- alphanumeric reports and graphical display of the interphase exchange of momentum, heat, and mass
- optionally, alphanumeric reports and graphical display of various cell-averaged discrete phase field variables
- sampling of trajectories at boundaries and lines/planes
- summary reporting of current particles in the domain
- histograms of trajectory data at sample planes
- display of erosion/accretion rates
- exporting of trajectories to Fieldview and Ensight

This section provides detailed descriptions of each of these postprocessing options.

(Note that plotting or reporting trajectories does not change the source terms.)

For additional information, see the following sections:
23.7.1. Displaying of Trajectories
23.7.2. Reporting of Trajectory Fates
23.7.3. Step-by-Step Reporting of Trajectories
23.7.4. Reporting of Current Positions for Unsteady Tracking
23.7.5. Reporting of Interphase Exchange Terms (Discrete Phase Sources)
23.7.6. Reporting of Discrete Phase Variables
23.7.7. Reporting of Unsteady DPM Statistics
23.7.8. Sampling of Trajectories
23.7.9. Histogram Reporting of Samples
23.7.10. Summary Reporting of Current Particles
23.7.11. Postprocessing of Erosion/Accretion Rates

23.7.1. Displaying of Trajectories

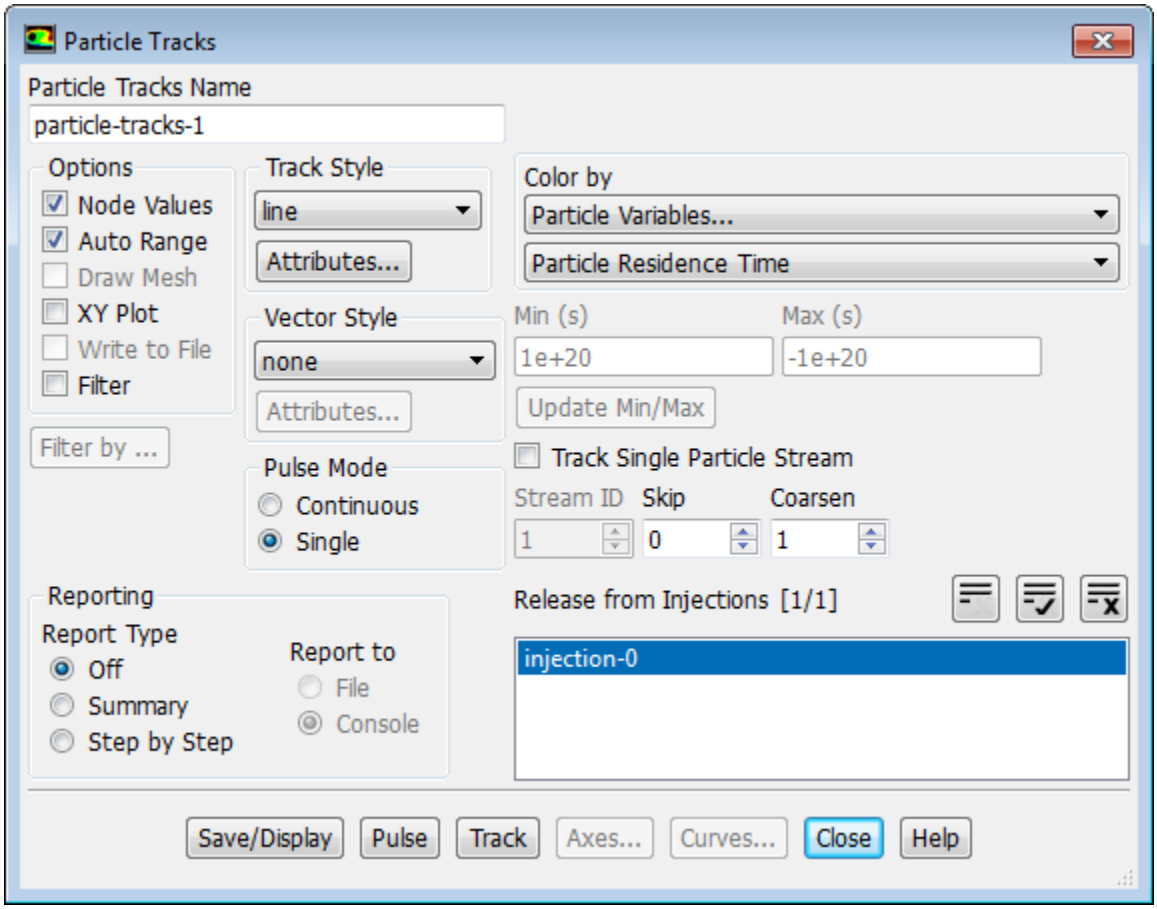
When you have defined discrete phase particle injections, as described in Setting Initial Conditions for the Discrete Phase (p. 1265), you can display the trajectories of these discrete particles using the Particle Tracks Dialog Box (p. 2761) (Figure 23.37: The Particle Tracks Dialog Box (p. 1331)).

You can create named particle track definitions and save them for later use. See Creating and Using Contour Plot Definitions (p. 1762) for additional information on graphics object definitions.

Results → Graphics → Particle Tracks → New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.37: The Particle Tracks Dialog Box



The procedure for drawing trajectories for particle injections is as follows:

1. Select the particle injection(s) you want to track in the **Release from Injections** list. (You can choose to track a specific particle, instead, as described below.)

2. Set the length scale and the maximum number of steps in the Discrete Phase Model Dialog Box (p. 2278), as described in Numerics of the Discrete Phase Model (p. 1260).

   Setup → Models → Discrete Phase Edit...

   If stochastic and/or cloud tracking is desired, set the related parameters in the **Set Injection Properties** dialog box, as described in Stochastic Tracking (p. 1294).

   Note

   Displaying tracks multiple times at the same solution state will result in identical random tracks. This is because the same random seeds are used enabling you to postprocess different variables on the same particle tracks.

3. Set any of the display options described below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Click the **Display** button to draw the trajectories or click the **Pulse** button to animate the particle positions. The **Pulse** button will become the **Stop !** button during the animation, and you must click **Stop !** to stop the pulsing.

Important

For unsteady particle tracking simulations, clicking **Display** will show only the current location of the particles. Typically, you should select **point** in the **Track Style** drop-down list when displaying transient particle locations since individual positions will be displayed. The **Pulse** button option is not available for unsteady tracking.

23.7.1.1. Specifying Particles for Display

You can display the trajectory for an individual particle stream instead of for all the streams in a given injection. Additionally, you can visualize the trajectories for the wall film particles (if they are present in the simulation) and/or free stream particles. To do so, you must first determine which particle is of interest. Use the Injections Dialog Box (p. 2716) to list the particle streams in the desired injection, as described in Creating and Modifying Injections (p. 1284).

Setup → Models → Discrete Phase → Injections Edit...

Note the ID numbers listed in the first column of the listing printed in the ANSYS Fluent console. Then perform the following steps after step 1 above. In the Particle Tracks Dialog Box (p. 2761):

1. Enable **Free Stream Particles** if you want to display those types of particles. Note that this option is available only when the Lagrangian wall film model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.

2. Enable **Wall Film Particles** if you want to display those types of particles. Note that this option is available only when the Lagrangian wall film model is enabled in the wall boundary conditions dialog box, under the **DPM** tab.

3. Enable the **Track Single Particle Stream** to display those types of particles.

4. In the **Stream ID** field, specify the ID number of the particle stream for which you want to plot the trajectory.

23.7.1.1.1. Controlling the Particle Tracking Style

Particle tracking can be displayed as lines (with or without arrows), ribbons, cylinders (coarse, medium, or fine), triangles, spheres, or a set of points. You can choose **line**, **line-arrows**, **point**, **sphere**, **ribbon**, **triangle**, **coarse-cylinder**, **medium-cylinder**, or **fine-cylinder** in the **Track Style** drop-down list in the **Particle Tracks** dialog box. Pulsing can be done only on **point**, **sphere**, or **line** styles.

Once you have selected the track style, click the **Attributes...** button to specify how you would like to display the particle tracks.

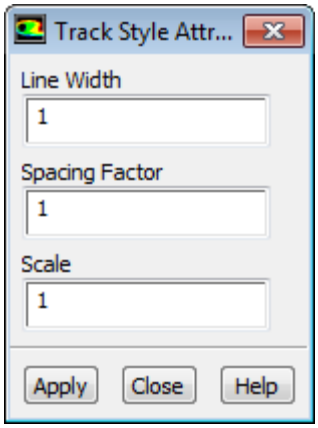
Note

The **Track Style** options that will appear depend on whether you are running a transient or steady-state simulation. For a transient case, the only **Track Style** options available are the **point** and **sphere** styles.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you are using the **line** or **line-arrows** style, set the **Line Width** in the **Track Style Attributes** dialog box (Figure 23.38: The Track Style Attributes Dialog Box (p. 1333)) that appears when you click the **Attributes...** button. For **line-arrows** you will also set the **Spacing Factor**, which controls the spacing between the particles tracks. The size of the arrow heads can be adjusted by entering a value in the **Scale** text-entry box.

  Figure 23.38: The Track Style Attributes Dialog Box



- If you are using the **point** style, you will set the **Marker Size** in the **Track Style Attributes** dialog box. The thickness of the particle track will be the thickness of the marker.

- If you are using the **sphere** style, you will set the **Diameter**, **scale**, and **Detail** in the **Particle Sphere Style Attributes** dialog box (Figure 23.39: The Particle Sphere Style Attributes Dialog Box (p. 1334)). You have the option of specifying a constant diameter if you enable **Constant** under **Options** and you will then specify the **Diameter**. If you enable **Variable**, you can select a particle variable to estimate the size of the spheres. The spheres are scaled by the factor entered in the **Scale** entry box.

  The best constant diameter to use will depend on the dimensions of the domain, the view, and the particle density. However, an adequate starting point would be a diameter on the order of 1/4 of the average cell size or 1/4 step size. Units for the **Diameter** field correspond to the mesh dimensional units.

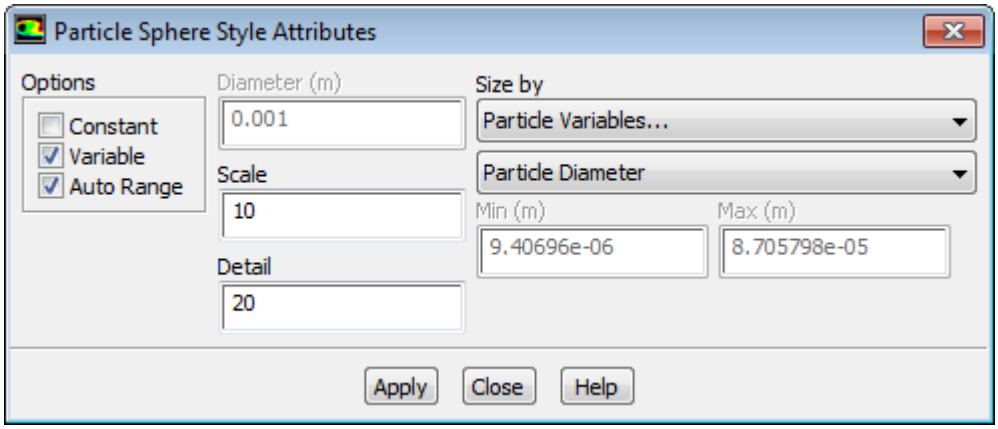
  The level of detail applied to the graphical rendering of the spheres can be controlled using the **Detail** field. The level of detail uses integer values ranging from 4 to 50. Note that the performance of the graphical rendering as well as the memory consumption will be better when using a small level of detail, that is, very coarse spheres, such as 6 or 8. The rendering performance significantly decreases with higher levels of detail. You should gradually increase the detail to determine the best-case scenario between performance and quality.

  Whenever **Auto Range** is disabled, the spheres are displayed only if they have values between **Min** and **Max**.

  Also note that to take full advantage of spherical rendering, lighting should be turned on in the view. The Gouraud setting provides much smoother looking spheres than the Flat setting and better performance than the Phong setting. For more information on lighting, see Adding Lights (p. 1796).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.39: The Particle Sphere Style Attributes Dialog Box



- If you are using the **triangle** or any of the **cylinder** styles, you will set the **Width** in the **Track Style Attributes** dialog box. For triangles, the specified value will be half the width of the triangle's base, and for cylinders, the value will be the cylinder's radius.

- If you are using the **ribbon** style, clicking on the **Attributes...** button will open the Ribbon Attributes Dialog Box (p. 2560), in which you can set the ribbon's **Width**. You can also specify parameters for twisting the ribbon tracks. In the **Twist By** drop-down list, you can select a scalar field on which the tracks twisting is based (for example, helicity). Select the desired category in the upper list and then select a related quantity in the lower list. The twisting may not be displayed smoothly because the scalar field by which you are twisting the tracks is calculated at cell centers only (and not interpolated to a particle's position). The **Twist Scale** sets the amount of twist for the selected scalar field. To magnify the twist for a field with very little change, increase this factor; to display less twist for a field with dramatic changes, decrease this factor.

  When you click **Compute**, the **Min** and **Max** fields will be updated to show the range of the **Twist By** scalar field.

23.7.1.1.2. Controlling the Vector Style of Particle Tracks

You can choose to have the particle tracks displayed as vectors. Choose the **Vector Style** from the drop-down list in the **Particle Tracks** dialog box:

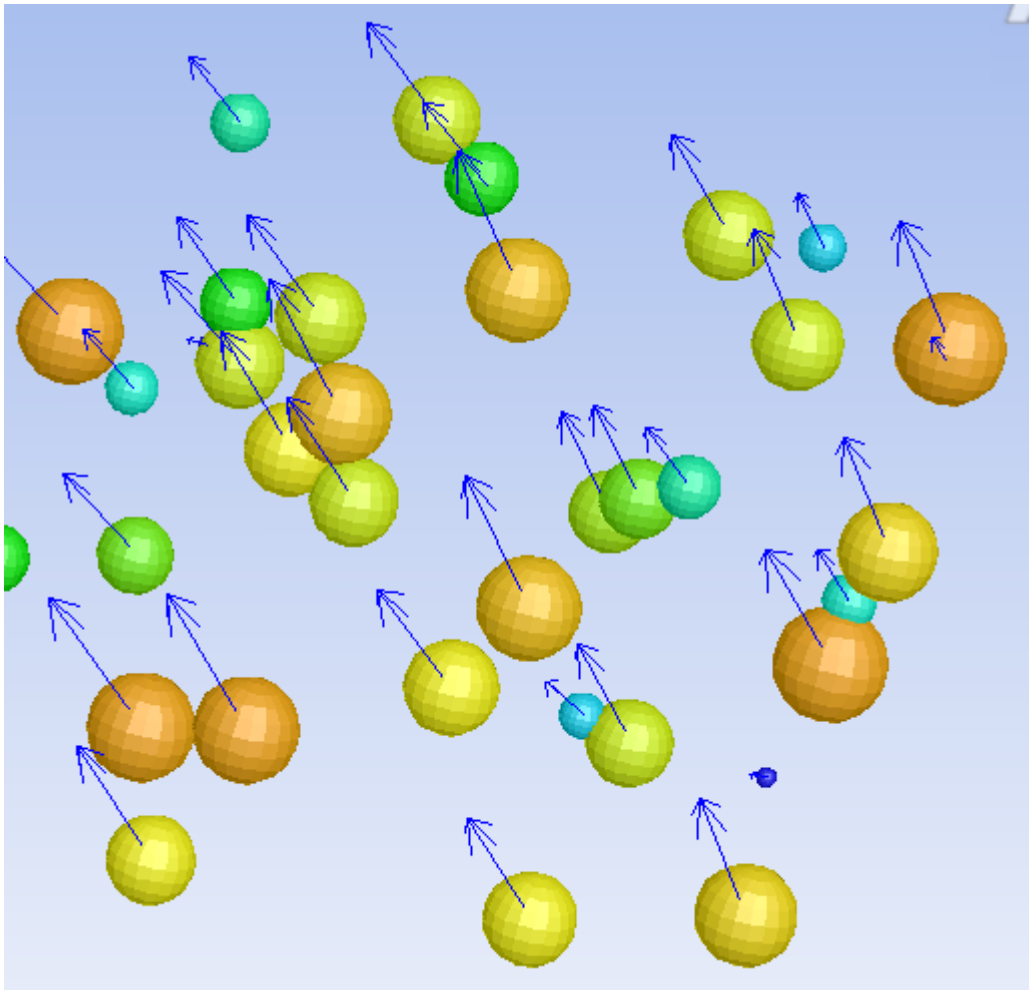
- If you select **vector**, the vector will be generated starting in the center of the particle, as shown in Figure 23.40: Particles with the Vector Style (p. 1335).

- If you select **centered-vector**, the midpoint of the vector will appear in the center of the particle, as shown in Figure 23.41: Particles with the Centered Vector Style (p. 1336).

- If you select **centered-cylinder**, the midpoint of the cylinder will appear in the center of the particle, as shown in Figure 23.42: Particles with the Centered Cylinder Style (p. 1337).

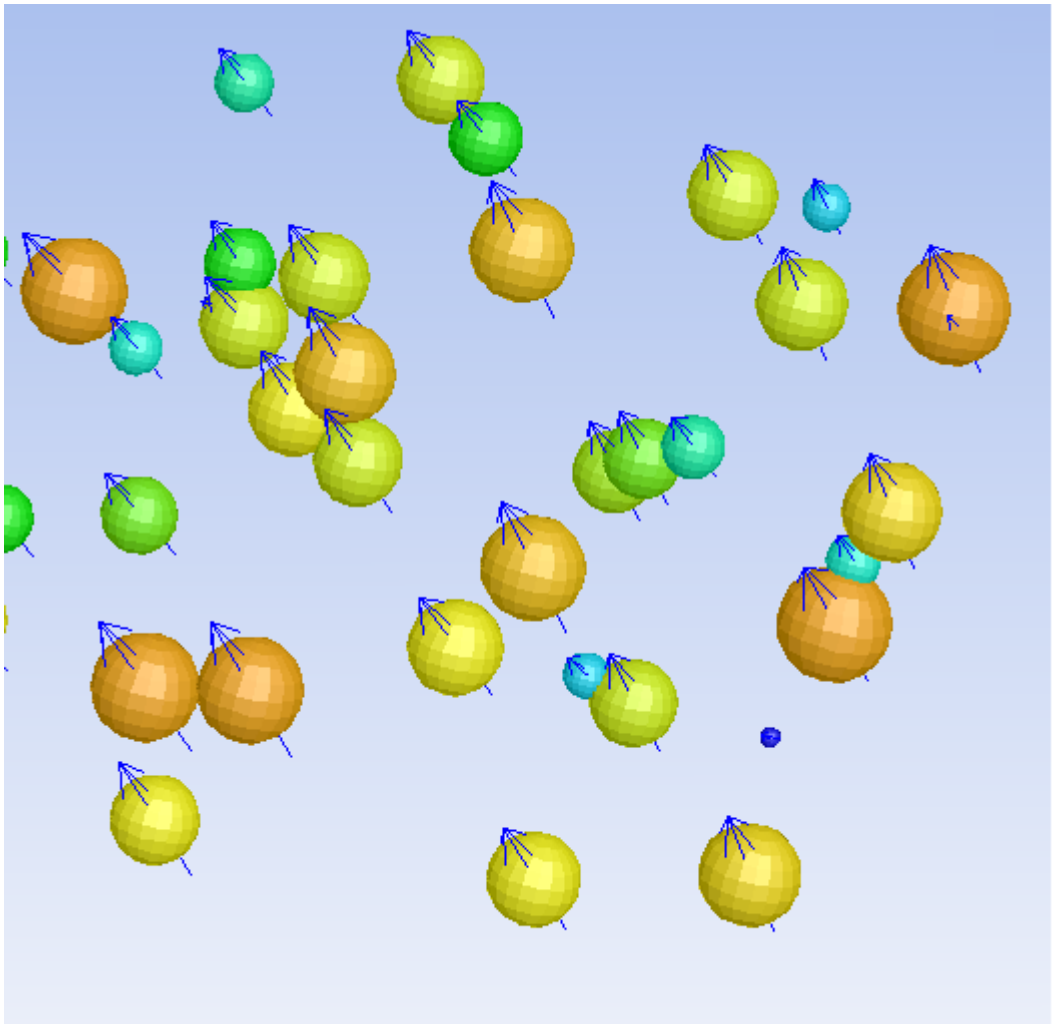
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.40: Particles with the Vector Style



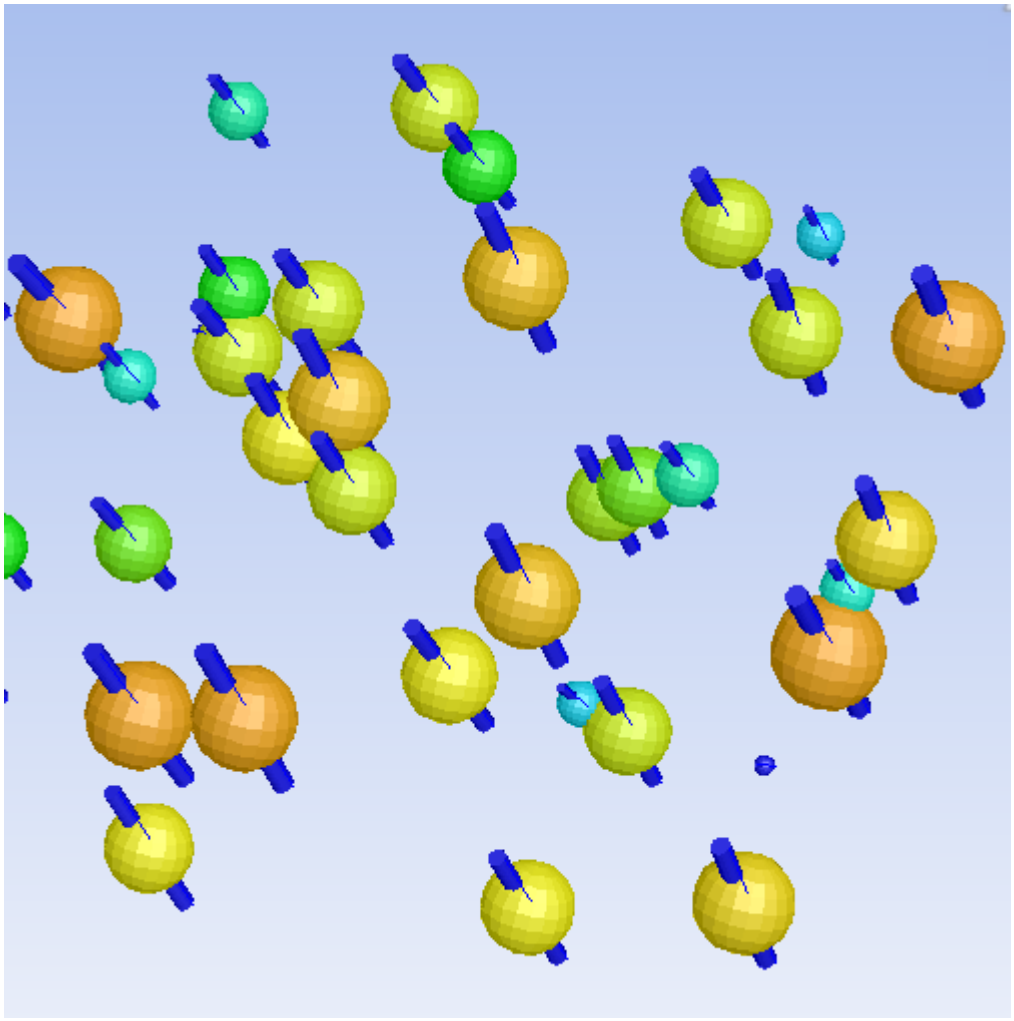
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.41: Particles with the Centered Vector Style



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.42: Particles with the Centered Cylinder Style

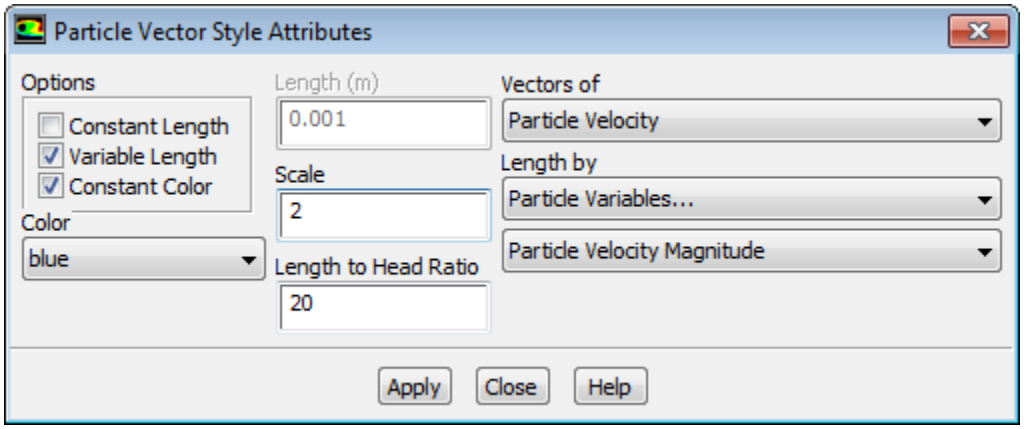


Click the **Attributes...** button to specify how you would like to display the particle tracks. In the **Particle Vector Style Attributes** dialog box (Figure 23.43: The Particle Vector Style Attributes Dialog Box (p. 1338)) you will set the **Length**, **Scale**, and **Length to Head Ratio**. The direction of the vectors is displayed for the selected variable under **Vectors of**. You have the option of specifying a **Constant Length** or a **Variable Length**, which is based on the variable selected under **Length by**. If **Constant Color** is enabled, then all vectors/cylinders are colored by the color selected in the **Color** drop-down list. Otherwise, it is the color selected in the **Particle Tracks** dialog box (seen in the **Mesh Colors** dialog box when **Draw Mesh** is enabled).

Vectors can be scaled by the factor given in the **Scale** entry box. The ratio of vector length to vector head size can be changed in the box **Length to Head Ratio**. In the case of a cylinder, the ratio of the length to the diameter is affected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.43: The Particle Vector Style Attributes Dialog Box

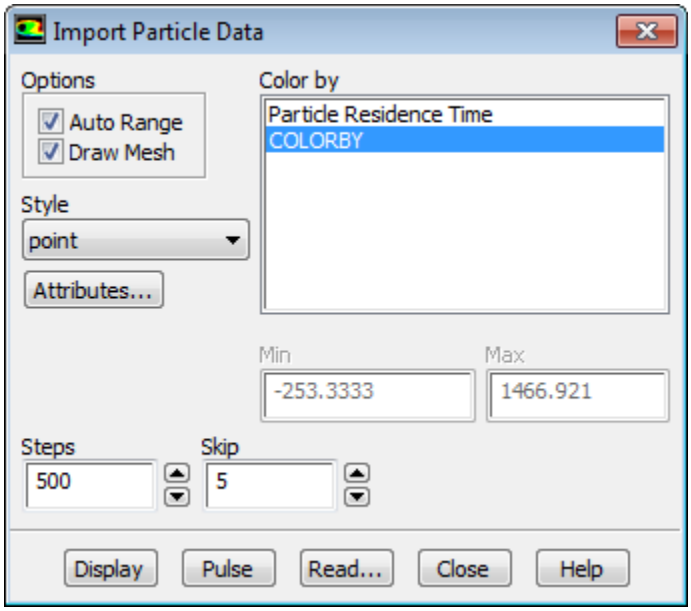


23.7.1.2. Importing Particle Data

Use the **Import Particle Data** dialog box (Figure 23.44: The Import Particle Data Dialog Box (p. 1338)) to import particle data to display in the graphics window.

Postprocessing → Model Specific → Discrete Phase → Import Particle Data...

Figure 23.44: The Import Particle Data Dialog Box



1. Click **Read...** to display a file selection dialog box where you can enter a file name and a directory that contains the imported data.

2. Choose from the available import options by selecting **Auto Range** and/or **Draw Mesh** under **Options**. If you prefer to restrict the range of the scalar field, disable the **Auto Range** option and set the **Min** and **Max** values manually beneath the **Color by** list.

3. Choose to color the particle pathlines by any of the scalar fields in the **Color by** list. If you select **COLORBY**, the pathlines will be colored by the quantity that was chosen when the particle data file was created. (See Exporting Steady-State Particle History Data (p. 84))

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

4. Select a pathline style under **Style**. To set pathline style attributes, click the **Attributes...** button. For more information about the pathline style types, see Controlling the Pathline Style (p. 1774).

5. The value of **Steps** sets the maximum number of steps a particle can advance. A particle will stop when it has traveled this number of steps or when it leaves the domain.

6. If your pathline plot is difficult to understand because there are too many paths displayed, you can "thin out" the pathlines by changing the **Skip** value.

7. Click the **Display** button to draw the pathlines, or click the **Pulse** button to animate the particle positions. The **Pulse** button will become the **Stop !** button during the animation, and you must click **Stop !** to stop the pulsing.

23.7.1.3. Options for Particle Trajectory Plots

You can include the mesh in the trajectory display, control the style of the trajectories (including the twisting of ribbon-style trajectories), color them by different scalar fields and control the color scale, and coarsen trajectory plots. You can also choose node or cell values for display. If you are "pulsing" the trajectories, you can control the pulse mode. Finally, you can generate an XY plot of the particle trajectory data (for example, residence time) as a function of time or path length and save this XY plot data to a file.

Note

The **Draw Mesh** option settings are not saved with the particle track plot definition. Once the dialog box is closed these settings will revert to being disabled. If you want these settings persisted within the current session, you can use the non-persistent **Particle Tracks** dialog box.

Postprocessing → **Graphics** → **Particle Tracks** → **Edit...**

Plotting particle trajectories can be very time consuming, therefore, to reduce the plotting time, a coarsening factor can be used to reduce the number of points that are plotted. Providing a coarsening factor of n, will result in each n^{th} point being plotted for a given trajectory in any cell. This coarsening factor is specified in the Particle Tracks Dialog Box (p. 2761), in the **Coarsen** field and is only valid for steady-state cases. For example, if the coarsening factor is set to 2, then ANSYS Fluent will plot alternate points.

Important

Note that if any particle or pathline enters a new cell, this point will always be plotted.

To reduce plotting time in transient cases, ANSYS Fluent has available an option to skip plotting every n^{th} particle in an injection. Selecting this option is also done in the Particle Tracks Dialog Box (p. 2761) by specifying a nonzero integer in the **Skip** field. For example, if an individual stream is selected and the skip option is set to 1, every other particle will be plotted. If the entire injection is selected with a skip option of 1, every other particle will be plotted for all streams in the injection.

These options are controlled in exactly the same way that pathline-plotting options are controlled. See Options for Pathline Plots (p. 1773) for details about setting the trajectory plotting options mentioned above.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Note that in addition to coloring the trajectories by continuous phase variables, you can also color them according to the following discrete phase variables: particle time, particle velocity, particle diameter, particle density, particle mass, particle temperature, particle law number, particle time step, and particle Reynolds number. If **DEM Collisions** is enabled in the **Discrete Phase Model** dialog box, you can also select the magnitude or components of the collisional force acting on the DEM parcel, total force acting on the DEM parcel, and total acceleration experienced by the particles in the parcel. These variables are included in the **Particle Variables...** category of the **Color by** list. To display the minimum and maximum values in the domain, click the **Update Min/Max** button.

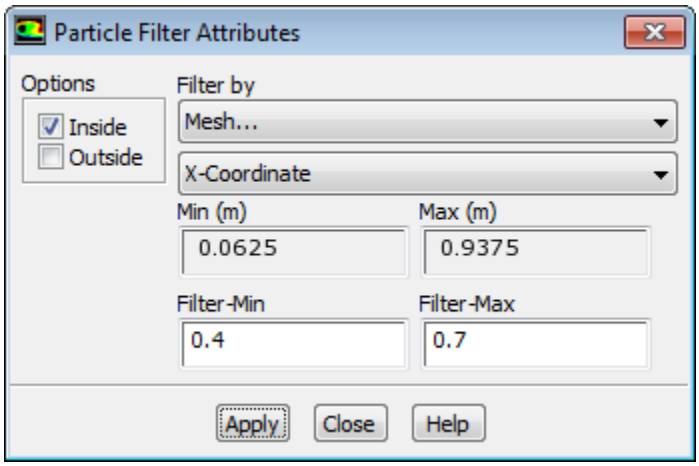
23.7.1.4. Particle Filtering

You can specify how you would like to filter the particles being displayed, by first enabling the **Enable Filter** option, then clicking the **Filter by...** button. In the **Particle Filter Attributes** dialog box, select the field variable by which you want to filter, then specify whether you would like to display all the particle tracks **Inside** or **Outside** the **Filter-Min** and **Filter-Max** range, as shown in Figure 23.45: The Particle Filter Attributes Dialog Box (p. 1340).

Note

All particle variables as well as any field variable except for **Custom Field Functions...** can be used as a filter variable.

Figure 23.45: The Particle Filter Attributes Dialog Box



23.7.1.5. Graphical Display for Axisymmetric Geometries

For axisymmetric problems in which the particle has a nonzero circumferential velocity component, the trajectory of an individual particle is often a spiral about the centerline of rotation. ANSYS Fluent displays the r and x components of the trajectory (but not the θ component) projected in the axisymmetric plane.

23.7.2. Reporting of Trajectory Fates

When you perform trajectory calculations by displaying the trajectories (as described in Displaying of Trajectories (p. 1330)), ANSYS Fluent will provide information about the trajectories as they are completed. By default, the number of trajectories with each possible fate (escaped, aborted, evaporated, and so on) is reported:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
DPM Iteration ....
 num. tracked = 7, escaped = 4, aborted = 0, trapped = 0, evaporated = 3, inco
Done.
```

You can also track particles through the domain without displaying the trajectories by clicking the **Track** button at the bottom of the dialog box. This allows the listing of reports without also displaying the tracks.

23.7.2.1. Trajectory Fates

The possible fates for a particle trajectory are as follows:

- "Escaped" trajectories are those that terminate at a flow boundary for which the "escape" condition is set.
- "Incomplete" trajectories are those that were terminated when the maximum allowed number of time steps — as defined by the **Max. Number of Steps** input in the Discrete Phase Model Dialog Box (p. 2278) (see Numerics of the Discrete Phase Model (p. 1260)) — was exceeded.
- "Incomplete_parallel" may appear as an additional fate for parallel simulations. This means that the number of particle exchanges between partitions has been exceeded. Any remaining particles on the compute nodes are stopped, which is indicated by the number following this fate. Therefore no further source terms from these particles are considered. The number of particle exchanges is limited to avoid very long computational time due to incomplete particles. You can change the default value of 1000 to a value of 20000 with a scheme command. Contact the technical support engineer for this information.
- "Trapped" trajectories are those that terminate at a flow boundary where the "trap" condition has been set.
- "Evaporated" trajectories include those trajectories along which the particles were evaporated within the domain.
- "Aborted" trajectories are those that fail to complete due to roundoff reasons. You may want to retry the calculation with a modified length scale and/or different initial conditions.
- "Shed" trajectories are newly generated particles during the breakup of a larger droplet. They appear only if a breakup model is enabled.
- "Coalesced" trajectories are removed particles which have coalesced after particle-particle collisions. They appear only if the coalescence model is enabled.
- "Splashed" trajectories are particles that are newly generated when a particle touches a wall film. Those trajectories appear only if the wall film model is enabled.

23.7.2.2. Summary Reports

You can request additional detail about the trajectory fates as the particles exit the domain, including the mass flow rates through each boundary zone, mass flow rate of evaporated droplets, and composition of the particles.

1. Follow steps 1 and 2 in Displaying of Trajectories (p. 1330) for displaying trajectories.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Select **Summary** as the **Report Type** and click **Display** or **Track**.

> **Important**
>
> For steady-state simulations, DPM summary data is not stored in the `.dat` file, since it is possible to track particles on single or combinations of injections. Transient simulations store this data since it is accumulated over time starting from initialization.

A detailed report similar to the following example will appear in the console window. (You may also choose to write this report to a file by selecting **File** as the **Report to** option, clicking the **Write...** button (which was originally the **Display** button), and specifying a file name for the summary report file in The Select File Dialog Box (p. 19).)

```

The report groups together particles with each possible fate, and reports the number of particles, the time elapsed during trajectories, and the mass and energy transfer This information can be very useful for obtaining information such as where particles are escaping from the domain, where particles are colliding with surfaces, and the extent of heat and mass transfer to/from the particles within the domain. Additional information is reported for combusting particles and multicomponent particles.

23.7.2.2.1. Elapsed Time

The number of particles with each fate is listed under the Number heading. (Particles that escape through different zones or are trapped at different zones are considered to have different fates, and are therefore listed separately.) The minimum, maximum, and average time elapsed during the trajectories of these particles, as well as the standard deviation about the average time, are listed in the Min, Max, Avg, and Std Dev columns. This information indicates how much time the particle(s) spent in the domain before they escaped, aborted, evaporated, or were trapped.

```
Fate          Number                          Elapsed  Time  (s)
                                      Min           Max            Avg       Std  Dev

23.7.2.2.2. Mass Transfer Summary

For all droplet or combusting particles with each fate, the total initial and final mass flow rates and the change in mass flow rate are reported in the Initial, Final, and Change columns. With this information, you can determine how much mass was transferred to the continuous phase from the particles.

For unsteady tracking, the report lists the time-integrated mass flow rate of the particle streams that have reached a particular fate at the current flow time. In other words, the report does not include particles that are still being tracked in the domain.

```

```

23.7.2.2.3. Energy Transfer Summary

This report tells you how much heat was transferred from the particles to the continuous phase. The report is organized in two sections. For steady simulations, there is a Heat Rate and a Change of Heat section. For unsteady particle tracking, there is an Energy and a Change of Energy section. The Heat Rate and Energy sections are the same for all particle types, while the other sections report the change of heat due to the various transfer processes, which differ for each particle type. For steady simulations, the report lists the rate and the change of heat for the particle streams organized according

to the particle stream fates. For unsteady tracking, the report lists the time integrated heat rate and change of the particle streams that have reached a particular fate at the current flow time. Note that the report does not include particles that are still being tracked in the domain.

23.7.2.2.4. Heat Rate and Energy Reporting

For all particles with each fate, the total initial and final heat content are reported in the `Initial` and `Final` columns. The particle heat content H_p is defined as follows:

Inert Particles:

$$H_p = m_p \int_{T_{ref}}^{T_p} C_{p_p} dT \tag{23.14}$$

where:

m_p = mass flow rate of particles (kg/s)

T_p = temperature of particles (K)

C_{p_p} = heat capacity of particles (J/kg/K)

T_{ref} = reference temperature for enthalpy (K)

Droplet Particles:

$$H_p = m_p [f_v \left(-H_{lat_{ref}} + H_{pyrol} \right) + \int_{T_{ref}}^{T_p} C_{p_p} dT] \tag{23.15}$$

where:

H_{pyrol} = heat of pyrolysis (J/kg)

$H_{lat_{ref}}$ = latent heat of evaporation at reference conditions (J/kg)

The latent heat at the reference conditions $H_{lat_{ref}}$ is defined in Equation 16.437 in the Theory Guide.

Combusting Particles:

$$H_p = H_w + H_{dry} \tag{23.16}$$

H_w is the heat content of the evaporating/boiling liquid material if Wet Combustion is selected (otherwise $H_w = 0$).

$$H_w = f_w m_p \left[\left(-H_{lat_{ref}} + H_{pyrol} \right) + \int_{T_{ref}}^{T_p} C_{p_p} dT \right] \tag{23.17}$$

where:

f_w is the mass fraction of the liquid in the combusting particle

$H_{lat_{ref}}$, H_{pyrol}, and C_{p_p} are properties of the evaporating liquid material

H_{dry} is the heat content of the dry combusting particle and is calculated as

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$H_{dry}=\left(1-f_w\right)m_p\left[f_v\left(-H_{lat_{ref}}\right)+f_{comb}H_{comb}+\int_{T_{ref}}^{T_p}C_{p_p}dT\right] \tag{23.18}$$

where:

f_v is the volatile fraction

f_{comb} is the combustible fraction

Important

The Heat Rate section of the report is not provided for the multiple surface reactions model.

Multicomponent Particles:

$$H_p=m_p\sum_i\left(y_iH_{p_i}\right) \tag{23.19}$$

where:

y_i = mass fraction of component i in particle

H_{p_i} = heat content of component i

and

$$H_{p_i}=\left[-H_{lat_{ref_i}}+H_{pyrol_i}+\int_{T_{ref}}^{T_p}C_{p_{p_i}}dT\right] \tag{23.20}$$

where:

H_{pyrol_i} = heat of pyrolysis for component i (J/kg)

$H_{lat_{ref_i}}$ = latent heat of evaporation at reference conditions for component i (J/kg)

$C_{p_{p_i}}$ = specific heat of component i (J/kg/K)

23.7.2.2.4.1. Change of Heat and Change of Energy Reporting

This section reports the total heat transferred from the particle to the continuous phase and is analyzed in components of Sensible heat, Latent heat and heat of Reaction. The Total change reported equals the difference between the Initial and Final states of the particle streams. The sensible heat component is reported for all particle types, the latent heat for the droplet, combusting and multicomponent particle, while the heat of reaction is reported for the combusting particle type only. A positive Change of Heat denotes that heat is expelled from the continuous phase and absorbed by the particle, while a negative Change of Heat denotes heat is released by the particle to the continuous phase.

Steady and Transient Simulations

For steady simulations the report lists the heat rate H_p, while for unsteady tracking the time integrated energy E_p from time 0 to current flow time ts is reported.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$E_p = \int_0^{ts} H_P(t)\,dt \tag{23.21}$$

Below is an example of an Energy Transfer Summary report for evaporating droplets:

```

```

Important

In a coupled calculation, for all types of steady flows, the Total Net Change of Heat reported in the Energy Transfer Summary should balance with the opposite of the Sum over all fluid cells of the DPM Sensible Enthalpy Source. If this is not the case, this means that the coupled discrete-continuous phase calculation has not converged, and more DPM phase iterations are required. For more information on coupled calculations, see Performing Trajectory Calculations (p. 1325).

```
                              Sum
  DPM  Sensible  Enthalpy  Source                        (w)
 --------------------------------       --------------------
                           fluid-1                -388937.41
```

23.7.2.2.5. Combusting Particles

If combusting particles are present, ANSYS Fluent will include additional reporting on the volatiles and char converted. These reports are intended to help you identify the composition of the combusting particles as they exit the computational domain.

```
                  (*)-  Combusting  Particles  -(*)
 Fate                  Volatile  Content  (kg/s)           Char  Content  (kg/s)
                           Initial          Final     %Conv       Initial        Final     %Conv
 ----                   ----------     ----------   -------    ----------    ---------   -------
 Incomplete              6.247e-04      0.000e+00    100.00     5.691e-04    0.000e+00    100.00
 Escaped  -  Zone  7     6.758e-04      0.000e+00    100.00     6.158e-04    3.782e-05     93.86
```

The total volatile content at the start and end of the trajectory is reported in the Initial and Final columns under Volatile Content. The percentage of volatiles that has been devolatilized is reported in the %Conv column.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The total reactive portion (char) at the start and end of the trajectory is reported in the `Initial` and `Final` columns under `Char Content`. The percentage of char that reacted is reported in the `%Conv` column.

23.7.2.2.6. Combusting Particles with the Multiple Surface Reaction Model

If the multiple surface reaction model is used with combusting particles, ANSYS Fluent will include additional reporting on the mass of the individual solid species that constitute the particle mass.

```
        (*)-  Multiple  Surface  Reactions  -(*)
Fate                  Species       Species  Content  (kg/s)
                       Names       Initial        Final     %Conv
----                 -------    ----------   ----------   -------
Escaped  -  Zone  6     c<s>     6.080e-02    1.487e-06    100.00
Escaped  -  Zone  6     s<s>     3.200e-03    5.077e-06     99.84
Escaped  -  Zone  6      cao     0.000e+00    1.153e-03      0.00
Escaped  -  Zone  6    caso4     0.000e+00    9.266e-04      0.00
Escaped  -  Zone  6    caco3     8.000e-03    5.260e-03     34.25
```

The total mass of each solid species in the particles at the start and end of the trajectory is reported in the `Initial` and `Final` columns, respectively. The percentage of each species that is reacted is reported in the `%Conv` column. Note that for the solid reaction products (for example, if the mass of a solid species has increased in the particle), the conversion is reported to be 0.

23.7.2.2.7. Multicomponent Particles

If your simulation includes multicomponent particles, ANSYS Fluent generates an additional report for the particle components.

```

```

23.7.3. Step-by-Step Reporting of Trajectories

At times, you may want to obtain a detailed, step-by-step report of the particle trajectory/trajectories. Such reports can be obtained in alphanumeric format. This capability allows you to monitor the particle position, velocity, temperature, or diameter as the trajectory proceeds.

The procedure for generating files containing step-by-step reports is listed below:

1. Follow steps 1 and 2 in Displaying of Trajectories (p. 1330) **Track Single Particle Stream** option.
2. Select **Step by Step** as the **Report Type**.

Important

This option is only available for steady-state cases. For transient cases, see Reporting of Current Positions for Unsteady Tracking (p. 1349).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select **File** as the **Report to** option. (The **Display** button will become the **Write...** button.)

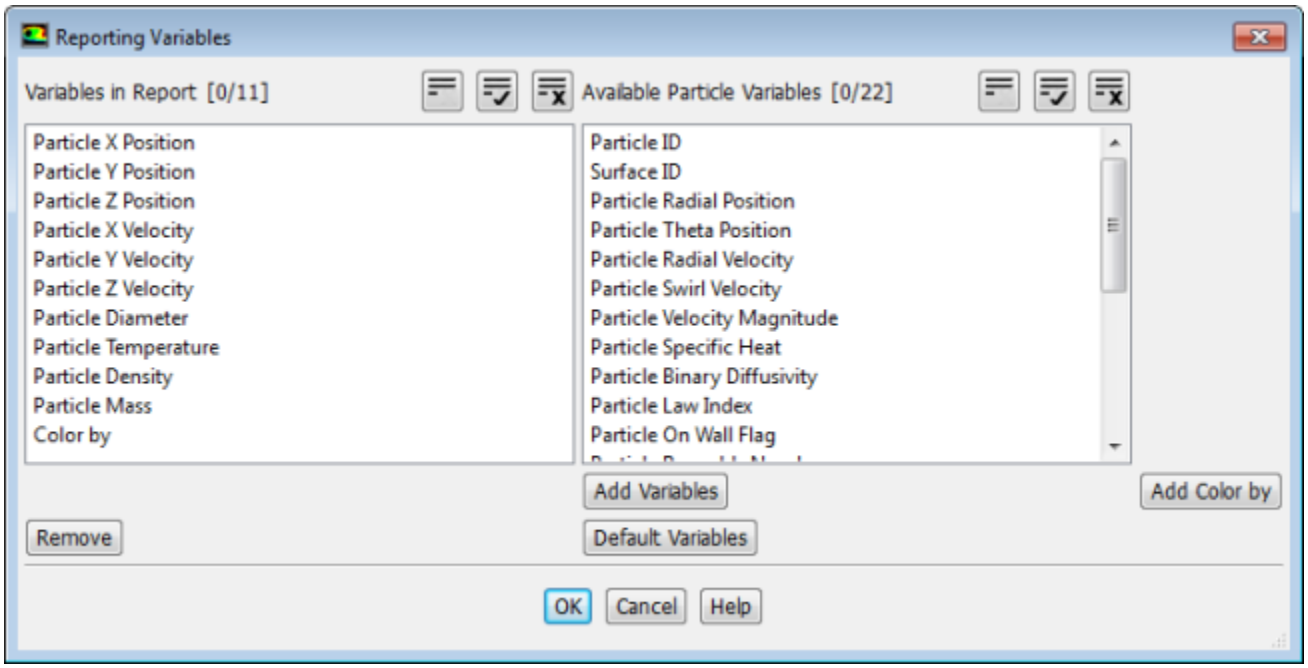
4. In the **Significant Figures** field, enter the number of significant figures to be used in the step-by-step report.

5. Click the **Reporting Variables...** button. The **Reporting Variables** dialog box will appear (Figure 23.46: The Reporting Variables Dialog Box (p. 1348)), where you can change the variables in the report. The list under **Variables in Report** contains all variables currently reported. The **Remove** button removes selected variables from that list. The **Default Variables** button restores the default list. The list under **Particle Variables** contains the particle variables that are available for you to select. You can add selections to the report using the **Add Variable** button. Clicking the **Add Color by** button adds the **Color by** variable to the list of **Variables in Report**, which is the only way to get cell values or customized field functions into the report.

Important

Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

Figure 23.46: The Reporting Variables Dialog Box



6. Click the **Write...** button and specify a file name for the step-by-step report file in The Select File Dialog Box (p. 19).

A detailed report similar to the following example will be saved to the specified file before the trajectories are plotted. (You may also choose to print the report in the console by choosing **Console** as the **Report to** option and clicking **Display** or **Track**, but the report is very long that it is unlikely to be of use to you in that form.)

  1.07087e-07   5.00000e-02   5.00000e-02   5.00000e-02   1.23339e+01   2.6696  .  .  .
  2.51617e-07   5.00000e-02   5.00000e-02   5.00000e-02   1.04417e+01   3.3286  .  .  .
 .              .             .             .             .             .
 .              .             .             .             .             .
 .              .             .             .             .             .
```

The default step-by-step report lists the position, velocity, diameter, temperature, density and mass of the particle at selected time steps along the trajectory. In addition, the variable you have selected in the **Color by** list is also included. If you choose **Console** as the **Report to** option, the variable names are written as the header of each column. (You may need to use the scroll bar to view all variables in this column.)

```
Time       X-Position   Y-Position   Z-Position    X-Velocity   Y-Velocity    Z-Veloc
0.000e+00  1.000e-03    3.120e-02    0.000e+00    1.000e+01     5.000e+00     0.000e

6.675e-05  1.680e-03    3.153e-02    0.000e+00    1.038e+01     4.954e+00     0.000e
8.338e-05  1.854e-03    3.161e-02    0.000e+00    1.047e+01     4.942e+00     0.000e
.          .            .            .            .             .             .
.          .            .            .            .             .             .
.          .            .            .            .             .             .
```

If you change the reporting variables, only those selected will appear in the report. The particle time is always reported in the first column. Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

When the report is written to a file, a table at the beginning of the file lists all variables selected with the corresponding unit. Thus you can display or export any variable along a particle trajectory to the console or to a file.

Note that the **Coarsen** option affects the step-by-step report.

23.7.4. Reporting of Current Positions for Unsteady Tracking

In transient cases, when using unsteady tracking, you may want to obtain a report of the particle trajectory/trajectories showing the current positions of the particles. Selecting **Current Positions** under **Report Type** in the Particle Tracks Dialog Box (p. 2761) enables the display of the current positions of the particles.

The procedure for generating files containing current position reports is listed below:

1. Follow steps 1 and 2 in Displaying of Trajectories (p. 1330) for displaying trajectories. You may want to track only one particle stream at a time, using the **Track Single Particle Stream** option.

2. Select **Current Position** as the **Report Type**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Select **File** as the **Report to** option. (The **Display** button will become the **Write...** button.)

4. In the **Significant Figures** field, enter the number of significant figures to be used in the report.

5. Click the **Reporting Variables...** button. The **Reporting Variables** dialog box will appear (Figure 23.46: The Reporting Variables Dialog Box (p. 1348)), where you can change the variables in the report. The list under **Variables in Report** contains all variables currently reported. The **Remove** button removes selected variables from that list. The **Default Variables** button restores the default list. The list under **Particle Variables** contains the particle variables that are available for you to select. You can add selections to the report using the **Add Variable** button. Clicking the **Add Color by** button adds the **Color by** variable to the list of **Variables in Report**, which is the only way to get cell values or customized field functions into the report.

   Important

   Note that it is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

6. Click the **Write...** button and specify a file name for the current position report file in The Select File Dialog Box (p. 19).

The default current position report lists the position, velocity, diameter, temperature, density, mass and number in parcel of the particle at selected time steps along the trajectory. In addition, the variable you have selected in the **Color by** list is also included. If you change the reporting variables, only those selected will appear in the report. The particle time is always reported in the first column. It is possible to select one variable in the **Reporting Variables** dialog box and a variable from the **Color by** drop-down list in the **Particle Tracks** dialog box, however, each variable is reported only once.

The output to a file or to the console has the same format as the step-by-step report for steady-state cases.

```
   Time         X-Position    Y-Position    Z-Position   X-Velocity    Y-Velocity    Z-Velocity

```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

23.7.5. Reporting of Interphase Exchange Terms (Discrete Phase Sources)

ANSYS Fluent reports the magnitudes of the interphase exchange of momentum, heat, and mass in each control volume in your ANSYS Fluent model. You can display these variables graphically, by drawing contours, profiles, and so on. They are all contained in the **Discrete Phase Sources...** category of the variable selection drop-down list that appears in postprocessing dialog boxes:

- **DPM Mass Source**
- **DPM X,Y,Z Momentum Source**
- **DPM Swirl Momentum Source**
- **DPM Turbulent Kinetic Energy Source**
- **DPM Turbulent Dissipation Source**
- **DPM Sensible Enthalpy Source**
- **DPM Enthalpy Source**
- **DPM Burnout**
- **DPM Evaporation/Devolatilization**
- **DPM (species) Source**

See Field Function Definitions (p. 1931) for definitions of these variables.

Note that these exchange terms are updated and displayed only when coupled calculations are performed. Displaying and reporting particle trajectories (as described in Displaying of Trajectories (p. 1330) and Reporting of Trajectory Fates (p. 1340)) will not affect the values of these exchange terms.

The exchange terms are reported as the rate occurring in each cell. A unit cell depth is used for 2D cases, and a reference cell depth of 1 radian is used for 2D axisymmetric cases.

23.7.6. Reporting of Discrete Phase Variables

ANSYS Fluent reports various discrete phase particle/parcel quantities including erosion/accretion rates, radiation quantities, and (optionally) cell-averaged particle size, velocity, temperature, and so on. You can display these variables graphically, by drawing contours, profiles, and so on. They are accessed in the **Discrete Phase Variables...** category of the variable selection drop-down list that appears in postprocessing dialog boxes.

Several quantities are automatically available depending on the models being used in the simulation. For the cell-averaged quantities to be available, you must first enable **Mean Values** under **Contour Plots for DPM Variables** in the **Discrete Phase Model** dialog box, Discrete Phase Model Dialog Box (p. 2278). RMS quantities are also available for particle velocity and temperature by enabling **RMS Values**.

Note

Enabling Mean Values to track the cell-averaged variables will increase the memory requirements of your simulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The following lists specify those variables that are available automatically and those that require you to enable them

Variables available automatically

- **DPM Erosion Rate (Generic)**
- **DPM Erosion Rate (Finnie)**
- **DPM Erosion Rate (McLaury)**
- **DPM Erosion Rate (Oka)**
- **DPM Accretion Rate**
- **DPM Absorption Coefficient**
- **DPM Emission**
- **DPM Scattering**
- **DPM Concentration**
- **DPM (species) Concentration**
- **DPM Collision Rate**

Particle rotation variables (Particle rotation simulations only)

- **Angular X Velocity**
- **Angular Y Velocity**
- **Angular Z Velocity**
- **Angular Velocity Magnitude**
- **Angular Velocity** (in the **Particle Vector Style** dialog box)

Cell-averaged variables available when Mean Values are enabled

- **DPM Volume Fraction**
- **DPM Particles in Cell**
- **DPM Parcels in Cell**
- **DPM Number Density**
- **DPM X, Y, Z Velocity**
- **DPM Diameter**
- **DPM Density**
- **DPM Temperature**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **DPM Specific Heat**
- **DPM D20**
- **DPM D30**
- **DPM D32**
- **DPM Granular Temperature**
- **DPM Conc. of (component)**

RMS variables available when Mean Values and RMS Values are enabled

- **DPM RMS X, Y, Z Velocity**
- **DPM RMS Temperature**
- **DPM RMS Diameter**

See Field Function Definitions (p. 1931) for definitions of these variables.

Note that these variables are updated and displayed only when coupled calculations are performed. Displaying and reporting particle trajectories (as described in Displaying of Trajectories (p. 1330) and Reporting of Trajectory Fates (p. 1340)) will not affect the values of these variables.

23.7.7. Reporting of Unsteady DPM Statistics

If you are performing a transient simulation, you can include the computation of unsteady time statistics (mean and RMS) for the discrete phase(s) of the transient flow. These are computed on a per-phase basis by event-based time averaging over the discrete phase parcels in the domain. This means that the sampling of the discrete phase particle quantity in a given cell occurs when (and only when) a parcel passes through the cell.

To calculate the unsteady DPM time statistics, enable **Data Sampling for Time Statistics** in the **Run Calculation** task page and enable **DPM Variables** in the **Sampling Options** dialog box when preparing to run your simulation (see User Inputs for Time-Dependent Problems (p. 1609)).

For a discrete phase variable, ϕ, the event-based time average in a cell is calculated from Equation 23.22 (p. 1353).

$$\langle \overline{\phi} \rangle = \frac{\sum_{i=1}^{N} \phi_i w_i}{\sum_{i=1}^{N} w_i} \tag{23.22}$$

where N is the number of parcels in the domain.

$$w_i = \frac{n_{p,i} t_i}{T_j} \tag{23.23}$$

Here $n_{p,i}$ is the number of particles in the i^{th} parcel and t_i is the residence time of the i^{th} parcel in the cell. T_j is the computational time step. The weighting by residence time is necessary because a parcel

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

may pass through more than one cell within a computational time step and therefore its contribution to the averaged cell quantities depends on the fraction of the time step spent in each cell.

The RMS value is also available and is computed from Equation 23.24 (p. 1354).

$$\phi_{rms}=\sqrt{\frac{\sum_{i=1}^{N}\left(\phi_i-\langle\overline{\phi}\rangle\right)^2 w_i}{\sum_{i=1}^{N} w_i}} \tag{23.24}$$

Note that these quantities are averaged over all parcels that have passed through the cell and are therefore different from the instantaneous cell-averaged values described in Reporting of Discrete Phase Variables (p. 1351).

Below is a list of the available unsteady statistics when **DPM Variables** is enabled in the **Sampling Options** dialog box. These are accessible by selecting the **Unsteady DPM Statistics...** category in postprocessing or reporting dialog boxes. Note that the availability of some quantities depends on the physics models being used. For definitions of these quantities, refer to the definitions of the instantaneous quantities from which they are derived (see Alphabetical Listing of Field Variables and Their Definitions (p. 1957)).

Unsteady DPM Statistics

- **Mean DPM Volume Fraction**
- **Accum DPM Particles in Cell**
- **Mean DPM X, Y, Z Velocity**
- **Mean DPM Diameter**
- **Mean DPM Density**
- **Mean DPM Temperature**
- **Mean DPM Granular Temperature**
- **Mean DPM Number Density**
- **Accum DPM Parcels in Cell**
- **Mean DPM D20**
- **Mean DPM D30**
- **Mean DPM D32**
- **Mean DPM Sauter Diameter**
- **RMS DPM Volume Fraction**
- **RMS DPM X, Y, Z Velocity**
- **RMS DPM Diameter**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

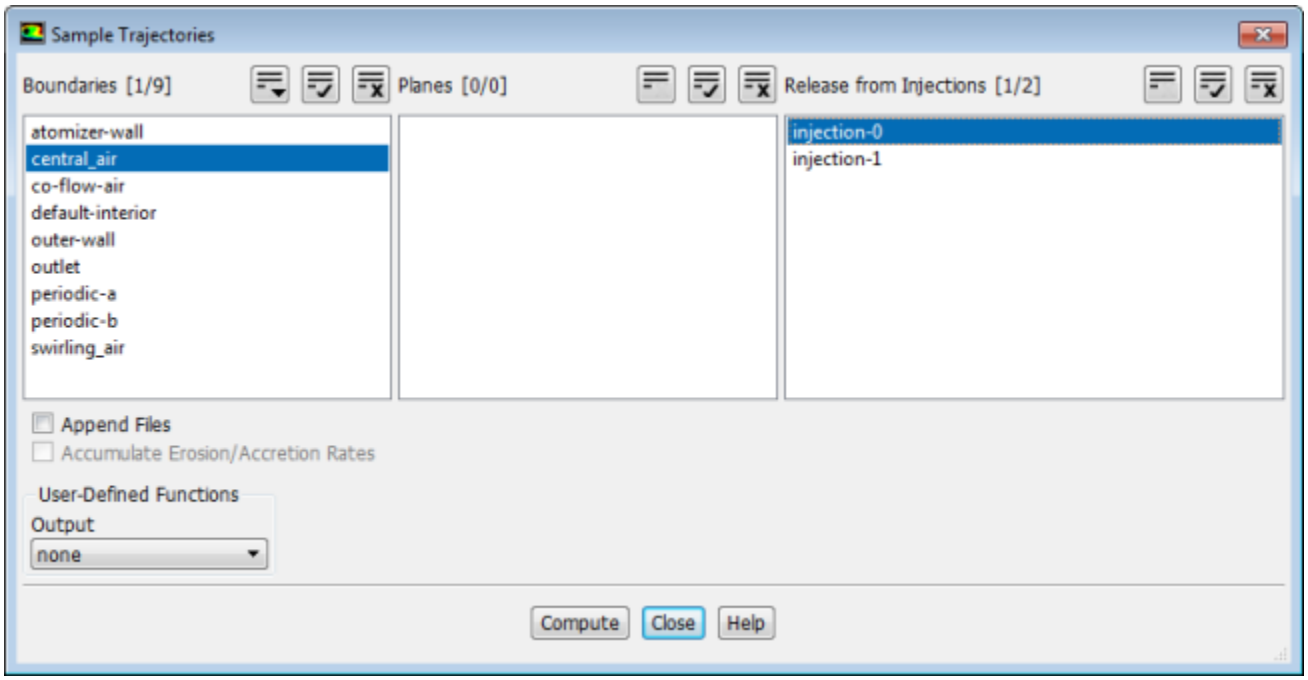
- **RMS DPM Density**
- **RMS DPM Temperature**
- **RMS DPM Granular Temperature**
- **RMS DPM Number Density**

23.7.8. Sampling of Trajectories

Particle states (position, velocity, diameter, temperature, and mass flow rate) can be written to files at various boundaries and planes (lines in 2D) using the Sample Trajectories Dialog Box (p. 2622) (Figure 23.47: The Sample Trajectories Dialog Box (p. 1355)).

Results → Reports → Discrete Phase → Sample → Edit...

Figure 23.47: The Sample Trajectories Dialog Box



The procedure for generating files containing the particle samples is listed below:

1. Select the injections to be tracked in the **Release From Injections** list.
2. Select the surfaces at which samples will be written These can be boundaries from the **Boundaries** list or planes from the **Planes** list (in 3D) or lines from the **Lines** list (in 2D).
3. Click the **Compute** button. Note that for unsteady particle tracking, the **Compute** button will become the **Start** button (to initiate sampling) or a **Stop** button (to stop sampling).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Clicking the **Compute** button will cause the particles to be tracked and their status to be written to files when they encounter selected surfaces. The file names will be formed by appending `.dpm` to the surface name.

Note

If you select a face zone in a mesh interface for sampling, Fluent will sample the particles on both of the interface zones and will write out a total of three files. Two of these files correspond to the particles that encounter each respective interface zone from upstream. The third file contains the complete set of particles that have crossed the mesh interface pair (via either interface zone).

For unsteady particle tracking, clicking the **Start** button will open the files and write the file header sections. If the solution is advanced in time by computing some time steps, the particle trajectories will be updated and the particle states will be written to the files as they cross the selected planes or boundaries. Clicking the **Stop** button will close the files and end the sampling.

For stochastic tracking, it may be useful to repeat this process multiple times and append the results to the same file, while monitoring the sample statistics at each update. To do this, enable the **Append Files** option before repeating the calculation (clicking **Compute**). Similarly, you can cause erosion and accretion rates to be accumulated for repeated trajectory calculations by turning on the **Accumulate Erosion/Accretion Rates** option. (See also Postprocessing of Erosion/Accretion Rates (p. 1360).) The format and the information written for the sample output can also be controlled through a user-defined function, which can be selected in the **Output** drop-down list. More information about user-defined functions can be found in the Fluent Customization Manual.

When sampling steady particle tracks the generated sample files can be used as injection file in a file injection. Both files use a similar file format.

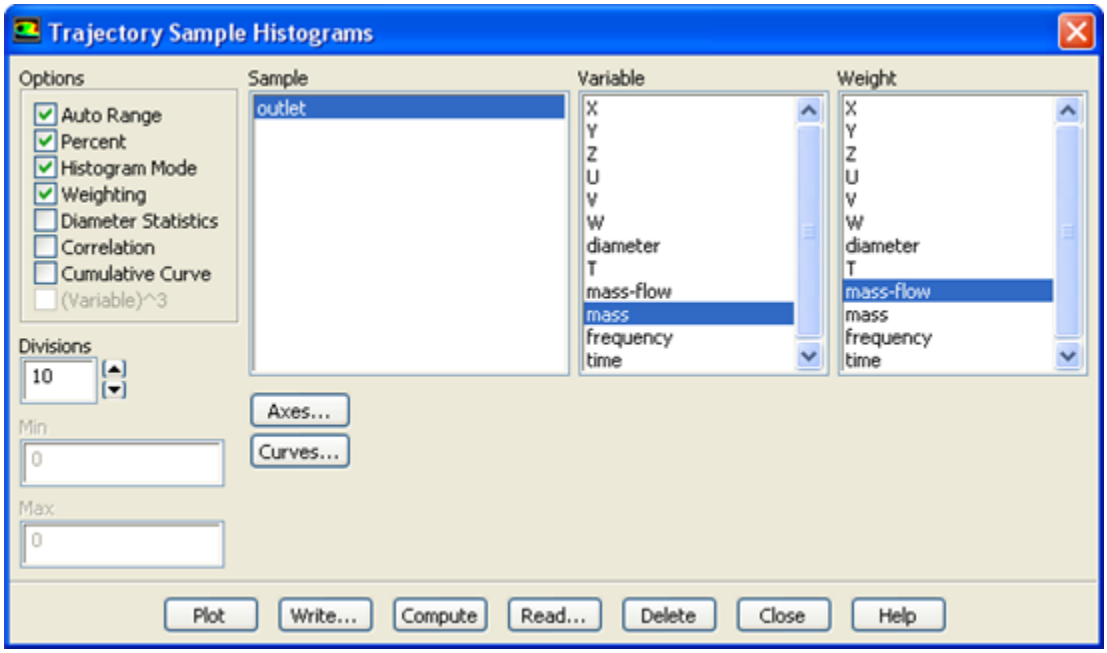
23.7.9. Histogram Reporting of Samples

Histograms can be plotted from sample files created in the Sample Trajectories Dialog Box (p. 2622) (as described in Sampling of Trajectories (p. 1355)) using the Trajectory Sample Histograms Dialog Box (p. 2623) (Figure 23.48: The Trajectory Sample Histograms Dialog Box (p. 1357)).

Results → Reports → Discrete Phase → Histogram Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.48: The Trajectory Sample Histograms Dialog Box



The procedure for plotting histograms from data in a sample file is listed below:

1. Select a file to be read by clicking the **Read...** button. After you read in the sample file, the boundary name will appear in the **Sample** list.

2. Select the data sample in the **Sample** list, and then select the data to be plotted from the **Variable** list.

3. Select the data to weight the variable from the **Weight** list.

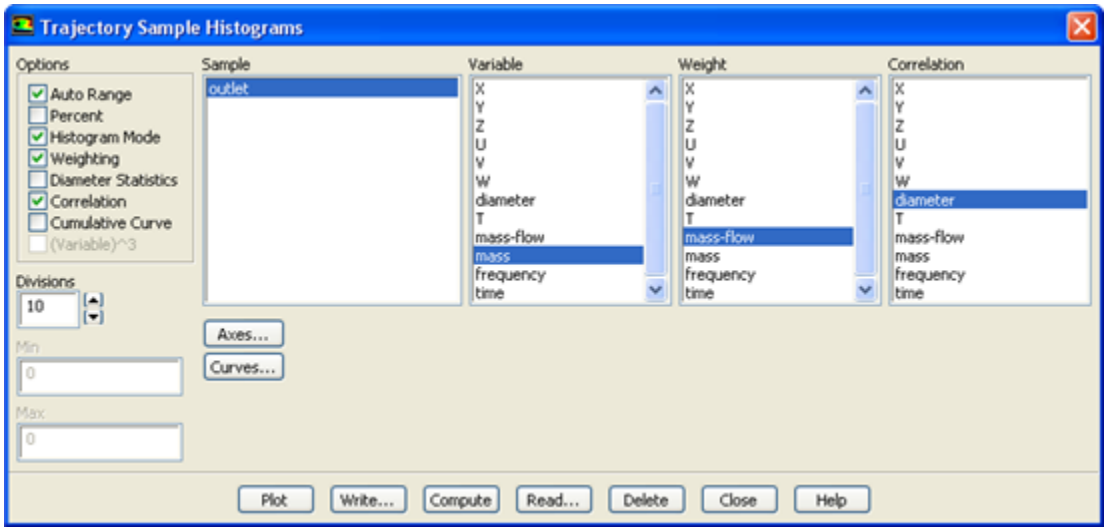
4. Click the **Plot** button at the bottom of the dialog box to display the histogram.

By default, the percent of particles will be plotted on the y axis. You can plot the actual number of particles by deselecting **Percent** under **Options**. The number of "bins" or intervals in the plot can be set in the **Divisions** field. You can delete samples from the list with the **Delete** button and update the **Min/Max** values with the **Compute** button. To display the histogram without the bars, deselect **Histogram Mode** under **Options**. A summary similar to that in Summary Reporting of Current Particles (p. 1358) will be displayed in the console for the selected variables when **Diameter Statistics** is enabled. Although these statistics are computed for the selected variable in the **Variable** list, it is applicable only to the diameter information. When the sampled particle streams all have the same flow rate, you can disable the **Weighting**. To postprocess the histograms with other tools, you can store them in an XY-plot file format using the **Write...** button.

When investigating the behavior of particles, it is sometimes desirable to know how one type of particle variable depends on another particle variable. To facilitate this, the **Correlation** option exists. When you enable this option, an additional column of sampled variables appears, allowing you to choose the correlation variable (see Figure 23.49: The Trajectory Sample Histograms Dialog Box (p. 1358)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.49: The Trajectory Sample Histograms Dialog Box



If you want to know the continuous cumulative distributions, enable the **Cumulative Curve** option. A cumulative distribution curve is computed of the variable that is selected in the **Variable** list. However, if the **Correlation** option is enabled along with the **Cumulative Curve**, then the cumulative curve of the variable selected in the **Correlation** list is plotted. For a constant particle density, you can plot the cumulative mass distribution by selecting the diameter and enabling `(Variable)^3`.

23.7.10. Summary Reporting of Current Particles

For many mass-transfer and flow processes, it is desirable to know the mean diameter of the particles. A mean diameter, D_{jk}, is calculated from the particle size distribution using the following general expression [55] (p. 2890):

$$\left(D_{jk}\right)^{j-k} \equiv \frac{\int_0^\infty D^j f(D)\,dD}{\int_0^\infty D^k f(D)\,dD} \tag{23.25}$$

where j and k are integers and $f(D)$ is the distribution function (for example, Rosin-Rammler). D_{10}, for example, is the average (arithmetic) particle diameter. The Sauter mean diameter (SMD), D_{32}, is the diameter of a particle whose ratio of volume to surface area is equal to that of all particles in the computation. A summary of common mean diameters is given in Table 23.6: Common Mean Diameters and Their Fields of Application (p. 1358).

Table 23.6: Common Mean Diameters and Their Fields of Application

j	k	**Order** $j+k$	**Name**	**Field of Application**
1	0	1	Mean diameter, D_{10}	Comparisons, evaporation
2	0	2	Mean surface diameter, D_{20}	Absorption
3	0	3	Mean volume diameter, D_{30}	Hydrology
2	1	3	Overall surface diameter, D_{21}	Adsorption

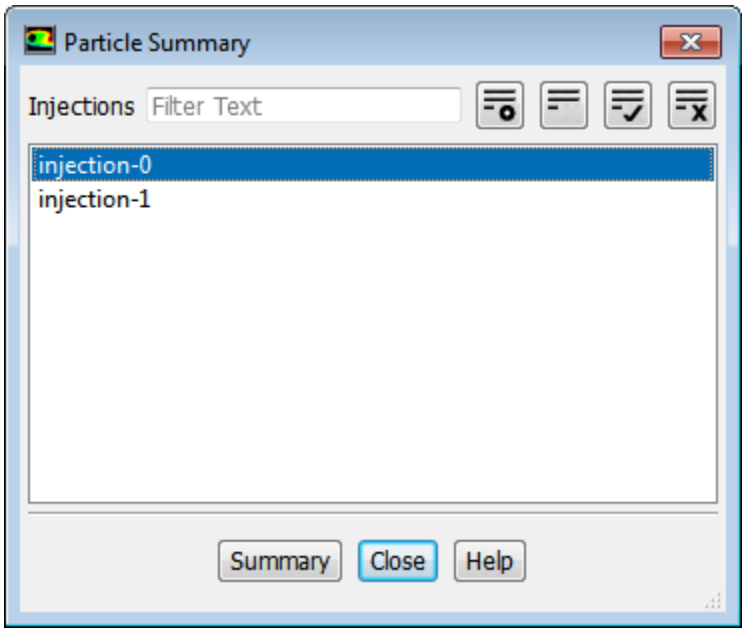
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

j	k	**Order** $j+k$	**Name**	**Field of Application**
3	1	4	Overall volume diameter, D_{31}	Evaporation, molecular diffusion
3	2	5	Sauter mean diameter, D_{32}	Combustion, mass transfer, and efficiency studies
4	3	7	De Brouckere diameter, D_{43}	Combustion equilibrium

Summary information (number, mass, average diameter) for particles currently in the computational domain can be reported using the Particle Summary Dialog Box (p. 2625) (Figure 23.50: The Particle Summary Dialog Box (p. 1359))

Results → Reports → Discrete Phase → Summary Edit...

Figure 23.50: The Particle Summary Dialog Box



The procedure for reporting a summary for particle injections is as follows:

1. Select the particle injection(s) you want summarized in the **Injections** list.

   Fluent provides a shortcut for selecting injections with names that match a specified pattern. To use this shortcut, enter the pattern in the **Filter Text** box. For example, if you specify `drop*`, all injections that have names beginning with **drop** (for example, **drop-1**, **droplet**) will be listed.

2. Click **Summary** to display the injection summary in the console window.

```
 (*)- Summary for Injection: injection-0 -(*)

```

23.7.11. Postprocessing of Erosion/Accretion Rates

You can calculate the erosion and accretion rates in a cumulative manner (over a series of injections) by using the **Sample Trajectories** dialog box. First select an injection in the **Release From Injections** list and compute its trajectory. Then enable the **Accumulate Erosion/Accretion Rates** option, select the next injection (after deselecting the first one), and click **Compute** again. The rates will accumulate at the surfaces each time you click **Compute**.

Important

Both the erosion rate and the accretion rate are defined at wall face surfaces only, so they cannot be displayed at node values.

23.8. Parallel Processing for the Discrete Phase Model

ANSYS Fluent offers three modes of parallel processing for the discrete phase model:

- **Shared Memory**

  The **Shared Memory** method is suitable for computations where the machine running the ANSYS Fluent host process is an adequately large, shared-memory, multiprocessor machine.

- **Message Passing**

  The **Message Passing** option is suitable for generic distributed memory cluster computing.

- **Hybrid** (default)

  The **Hybrid** option is suitable for modern multicore memory cluster computing.

These options are found under the **Parallel** tab, in the **Discrete Phase Model** dialog box.

Important

When tracking particles in parallel, the DPM model cannot be used with any of the multiphase flow models (VOF, mixture, or Eulerian) if the **Shared Memory** option is enabled. (Note that using the **Message Passing** or **Hybrid** option, when running in parallel, enables the compatibility of all multiphase flow models with the DPM model.)

If you want to use **file** injections or to write a DPM summary report directly to a file, your system must meet the following requirements when either the **Message Passing** or **Hybrid** parallel DPM tracking option is selected:

- The machine (for example, cluster node) running the compute-node zero process and the machine running the host process are identical or have the same operating system type (Windows or Linux)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Both machines can access the same file system through the same path specification

If these conditions are not met, you can still write a DPM summary report to a file by starting transcript, reporting the particle tracking summary to the Fluent console, and then stopping transcript. The summary report will be saved in the transcript file.

As a workaround for the DPM summary report, you can start transcript, report the particle tracking summary to the Fluent console, and stop transcript. The summary report will be saved in the transcript file

The **Shared Memory** option (Figure 23.51: The Shared Memory Option with Workpile Algorithm Enabled (p. 1362)) is implemented using POSIX Threads (pthreads) based on a shared-memory model. Once the **Shared Memory** option is enabled, you can then select along with it the **Workpile Algorithm** and specify the **Number of Threads**. By default, the **Number of Threads** is equal to the number of compute nodes specified for the parallel computation. You can modify this value based on the computational requirements of the particle calculations. If, for example, the particle calculations require more computation than the flow calculation, you can increase the **Number of Threads** (up to the number of available processors) to improve performance. When using the **Shared Memory** option, the particle calculations are entirely managed by the ANSYS Fluent host process. You must make sure that the machine executing the host process has enough memory to accommodate the entire mesh.

Important

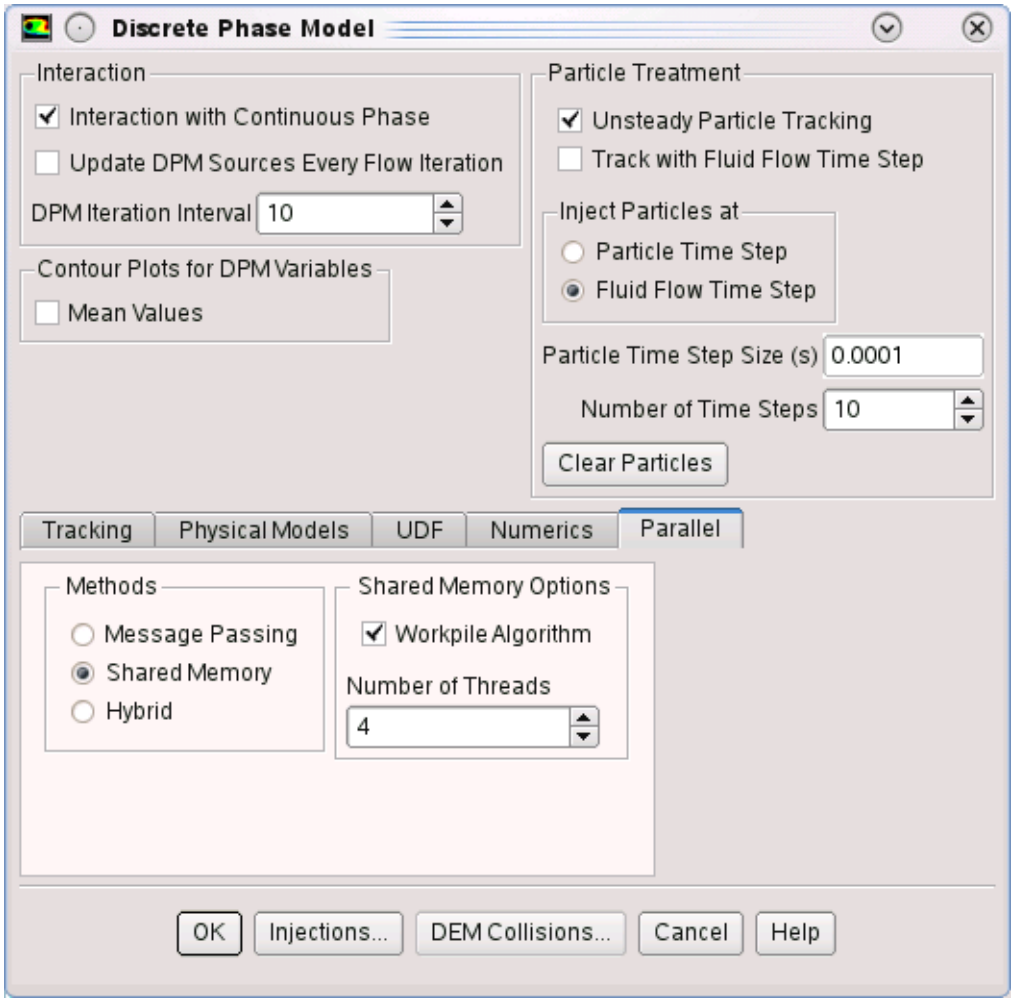
Note that the **Shared Memory** option on Windows based architectures only provides serial tracking on the host, since the **Workpile Algorithm** is not available due to lack of POSIX Threads on these platforms.

Important

Note that the **Workpile Algorithm** option is not available with the wall film boundary condition. It will be disabled automatically when choosing to simulate a wall film on a wall.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 23.51: The Shared Memory Option with Workpile Algorithm Enabled



The **Message Passing** option enables cluster computing and also works on shared-memory machines. With this option enabled, the compute node processes perform the particle work on their local partitions. Particle migration to other compute nodes is implemented using message passing primitives. There are no special requirements for the host machine. Note that this model is not available if the **Cloud Model** option is turned on under the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box. When running ANSYS Fluent in parallel, by default, pathline displays are computed in serial on the host node. Pathline displays may be computed in parallel on distributed memory systems if the **Message Passing** parallel option is selected in the **Discrete Phase Model** dialog box.

The **Hybrid** option combines **Message Passing** and **OpenMP** for a dynamic load balancing without migration of cells, enables multicore cluster computing, and also works on shared-memory machines. With this option enabled, the compute node processes perform the particle calculations on their local partitions. **OpenMP** threads will be spawned, and the number of threads in each ANSYS Fluent node process is based on the evaluation of the particle load on the current machine. The maximum number of threads on each machine can be controlled using the **Thread Control** dialog box (see Controlling the Threads (p. 2058) for details). The default value is the number of ANSYS Fluent node processes on each machine. Particle migration to other compute nodes is implemented using message passing primitives. There are no special requirements for the host machine. Note that this model is not available if the **Cloud Model** option is turned on under the **Turbulent Dispersion** tab of the **Set Injection Properties** dialog box. When running ANSYS Fluent in parallel, pathline displays are computed by default in serial on the host node. Pathline displays may also be computed in parallel on distributed memory

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

systems if the **Message Passing** option is selected from the **Methods** list. For a list of limitations that exist with Hybrid parallel method, see Limitations on Using the Hybrid Parallel Method (p. 1239).

When using the Hybrid method, you may optionally enable **Use DPM Domain** under **Hybrid Options**. This option can provide substantially improved load balancing, and thus scalability, at the expense of additional memory overhead. When **Use DPM Domain** is enabled, particle tracking is performed on a separate domain from the root computational domain. Flow and DPM variables are copied between the domains as part of the solution process. By using a separate domain, and thus partitioning strategy, for particle tracking the continuous and discrete phase loads are balanced independently. This allows the load to be shared more equally among the machines regardless of how particles are distributed throughout the computational domain. This is especially beneficial for simulations with non-uniform particle distributions over the computational domain. For limitations associated with the **Use DPM Domain** option, see Limitations on Using the Hybrid Parallel Method (p. 1239). To enable dynamic load balancing with this option, use the following text command:

`parallel` → `partition` → `set` → `dpm-load-balancing`

When this load balancing is enabled, you will be prompted to define a load imbalance threshold (that is, a percentage above which load balancing will occur), as well as the interval of DPM iterations at which you would like load balancing attempted. It is recommended that you retain the default values, as these are appropriate for a wide range of cases.

You may seamlessly switch among the **Shared Memory** option, the **Message Passing** option, and the **Hybrid** option at any time during the ANSYS Fluent session.

In addition to performing general parallel processing of the Discrete Phase Model, you have the option of implementing DPM-specific user-defined functions in parallel ANSYS Fluent. For more information about the parallelization of DPM UDFs, see Parallelization of Discrete Phase Model (DPM) UDFs in the Fluent Customization Manual.

When using the **Message Passing** or the **Hybrid** option you can make use of ANSYS Fluent's automated load balancing capability by giving an appropriate weight to the particle steps in each cell. In this case the number of particle steps in each partition is considered in the load balancing procedure. Further details can be found in Using the Partitioning and Load Balancing Dialog Box (p. 2033).

Chapter 24: Modeling Multiphase Flows

This chapter discusses the general multiphase models that are available in ANSYS Fluent. For information about the various theories behind the general multiphase models in ANSYS Fluent, see Multiphase Flows in the Theory Guide. Information about using the general multiphase models in ANSYS Fluent is presented in the following sections:

24.1. Introduction
24.2. Steps for Using a Multiphase Model
24.3. Setting Up the VOF Model
24.4. Setting Up the Mixture Model
24.5. Setting Up the Eulerian Model
24.6. Setting Up the Wet Steam Model
24.7. Solution Strategies for Multiphase Modeling
24.8. Multiphase Case Check
24.9. Postprocessing for Multiphase Modeling

24.1. Introduction

The first step in solving any multiphase problem is to determine which of the regimes described in Multiphase Flow Regimes in the Theory Guide best represents your flow. Model Comparisons in the Theory Guide provides some broad guidelines for determining appropriate models for each regime, and Detailed Guidelines provides details about how to determine the degree of interphase coupling for flows involving bubbles, droplets, or particles, and the appropriate model for different amounts of coupling.

The following sections will guide you through the setup, solution, and postprocessing of multiphase flow models.

24.2. Steps for Using a Multiphase Model

The procedure for setting up and solving a general multiphase problem is outlined below, and described in detail in the subsections that follow. Remember that only the steps that are pertinent to general multiphase calculations are shown here. For information about inputs related to other models that you are using in conjunction with the multiphase model, see the appropriate sections for those models.

See also Additional Guidelines for Eulerian Multiphase Simulations (p. 1455) for guidelines on simplifying Eulerian multiphase simulations.

Important

Double Precision is recommended for all multiphase cases.

1. Enable the multiphase model you want to use (VOF, mixture, or Eulerian) and specify the number of phases. For the VOF and Eulerian models, specify the volume fraction scheme as well.

   Setup → **Models** → **Multiphase** → **Edit...**

See Enabling the Multiphase Model (p. 1367) and Choosing Volume Fraction Formulation (p. 1371) for details.

2. Copy the material representing each phase from the materials database.

   Setup → Materials

   If the material you want to use is not in the database, create a new material. See Using the **Create/Edit Materials** Dialog Box (p. 461) for details about copying from the database and creating new materials. See Modeling Compressible Flows (p. 1375) for additional information about specifying material properties for a compressible phase. It is possible to turn off reactions in some materials by selecting **none** in the **Reactions** drop-down list under **Properties** in the **Create/Edit Materials** dialog box.

   Important

   If your model includes a particulate (granular) phase, you will need to create a new material for it in the *fluid* materials category (*not* the solid materials category).

3. Define the phases, and specify any interaction between them (for example, surface tension if you are using the VOF model, slip velocity functions if you are using the mixture model, or drag functions if you are using the Eulerian model).

   Setup → Models → Multiphase → Phases → Edit...

   See Defining the Phases (p. 1377) – Defining the Phases for the Eulerian Model (p. 1456) for details.

4. (Eulerian model only) If the flow is turbulent, define the multiphase turbulence model.

   Setup → Models → Viscous → Edit...

   See Modeling Turbulence (p. 1474) for details.

5. If body forces are present, enable gravity and specify the gravitational acceleration.

   Setup → Cell Zone Conditions → Operating Conditions...

   See Including Body Forces (p. 1377) for details.

6. Specify the boundary conditions, including the secondary-phase volume fractions at flow boundaries and (if you are modeling wall adhesion in a VOF simulation) the contact angles at walls.

   Setup → Boundary Conditions

   See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for details.

7. Set any model-specific solution parameters.

   Solution → Methods

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → **Controls**

See Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation (p. 1445) and Solution Strategies for Multiphase Modeling (p. 1504) for details.

8. Initialize the solution and set the initial volume fractions for the secondary phases.

   Solution → **Initialization** **Patch...**

   See Setting Initial Volume Fractions (p. 1407) for details.

9. Calculate a solution and examine the results. Postprocessing and reporting of results are available for each phase that is selected.

   See Solution Strategies for Multiphase Modeling (p. 1504) and Postprocessing for Multiphase Modeling (p. 1520) for details.

Note

For information on multiphase model compatibility with other Fluent models, see Appendix A: ANSYS Fluent Model Compatibility (p. 2847).

This section provides instructions and guidelines for using the VOF, mixture, and Eulerian multiphase models.

Information is presented in the following subsections:

24.2.1. Enabling the Multiphase Model
24.2.2. Choosing Volume Fraction Formulation
24.2.3. Solving a Homogeneous Multiphase Flow
24.2.4. The Boussinesq Approximation in Multiphase Flow
24.2.5. Modeling Compressible Flows
24.2.6. Defining the Phases
24.2.7. Including Body Forces
24.2.8. Modeling Multiphase Species Transport
24.2.9. Specifying Heterogeneous Reactions
24.2.10. Including Mass Transfer Effects
24.2.11. Defining Multiphase Cell Zone and Boundary Conditions
24.2.12. Setting Initial Volume Fractions

24.2.1. Enabling the Multiphase Model

To enable the VOF, mixture, or Eulerian multiphase model, select **Volume of Fluid**, **Mixture**, or **Eulerian** under **Model** in the Multiphase Model Dialog Box (p. 2171).

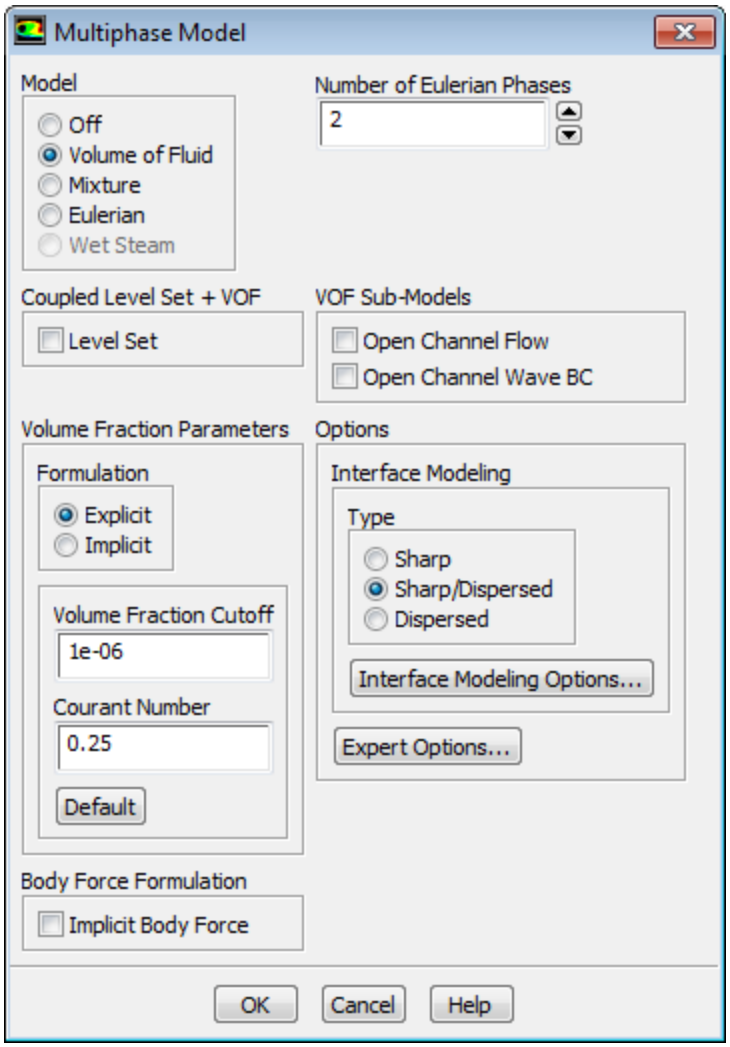
Setup → **Models** → **Multiphase** → **Edit...**

The dialog box will expand to show the relevant inputs for the selected multiphase model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Volume of Fluid Model Inputs

Figure 24.1: Multiphase Model Dialog Box for the VOF Model

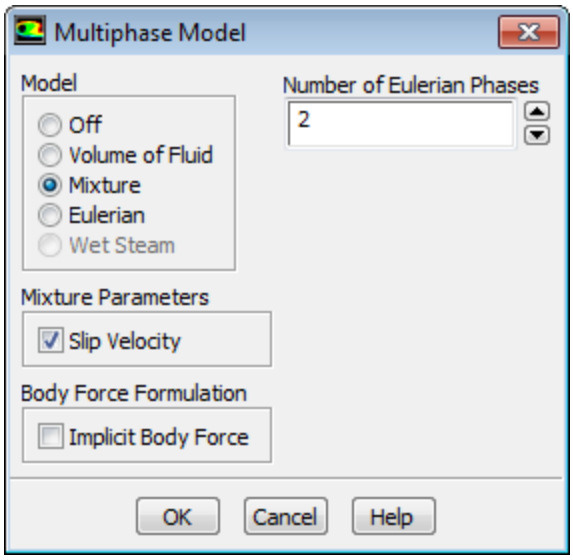


- **Number of Eulerian Phases**
- (optional) **Coupled Level Set + VOF** (see Coupled Level-Set and VOF Model in the Theory Guide)
- volume fraction **Formulation** (**Explicit** or **Implicit**) and associated parameters (see Choosing Volume Fraction Formulation (p. 1371))
- (optional) inclusion of sub-models such as **Open Channel Flow** and **Open Channel Wave BC**
- **Interface Modeling** type and options (see Choosing Volume Fraction Formulation (p. 1371))
- (optional) selection of **Expert Options** (see Expert Options (p. 1374))
- (optional) inclusion of the **Implicit Body Force** formulation (see Including Body Forces (p. 1377))

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Mixture Model Inputs

Figure 24.2: Multiphase Model Dialog Box for the Mixture Model

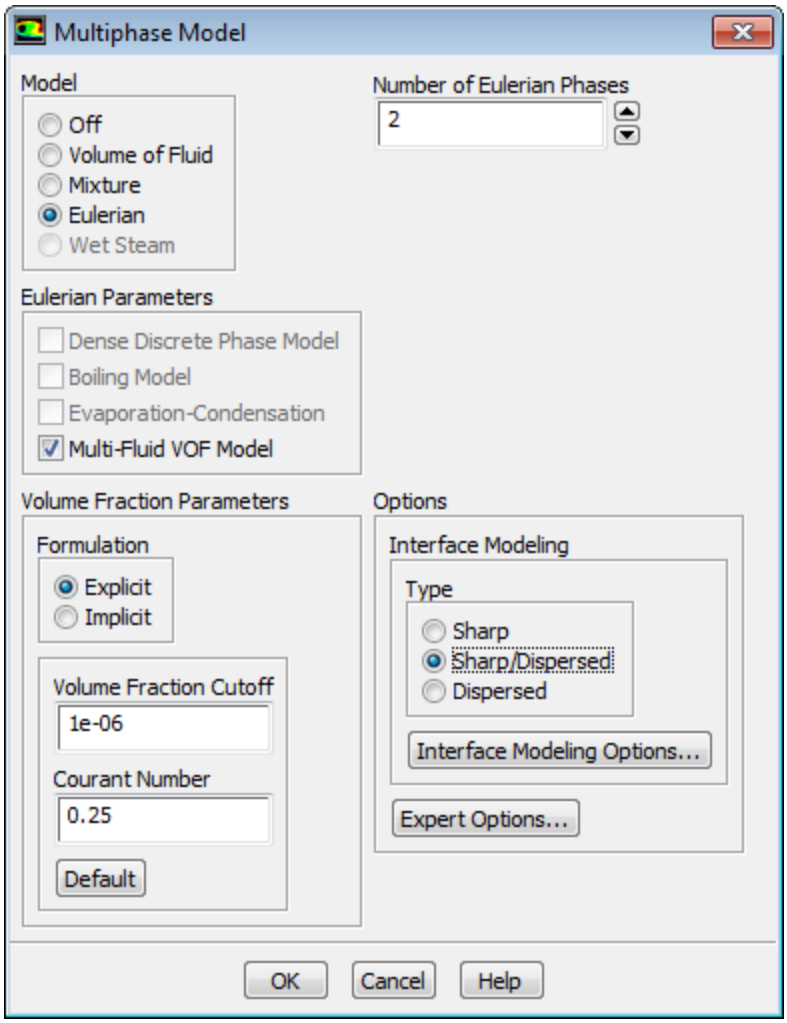


- **Number of Eulerian Phases**
- (optional) inclusion of **Slip Velocity** (see Solving a Homogeneous Multiphase Flow (p. 1375))
- (optional) inclusion of the **Implicit Body Force** formulation (see Including Body Forces (p. 1377))

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Eulerian Model Inputs

Figure 24.3: Multiphase Model Dialog Box for the Eulerian Model



- **Number of Eulerian Phases**
- (optional) inclusion of the **Dense Discrete Phase Model**
- (optional) inclusion of the **Boiling Model**
- (optional) inclusion of **Evaporation-Condensation** modeling
- (optional) inclusion of the **Multi-Fluid VOF Model**
- **Evaporation-Condensation Model Options** where you can choose whether to use the **Lee Model** or **Thermal Phase Change** model for interphase mass transfer.
- volume fraction **Formulation** (**Explicit** or **Implicit**) and associated parameters (see Choosing Volume Fraction Formulation (p. 1371))
- **Interface Modeling** type and options (see Choosing Volume Fraction Formulation (p. 1371)). This is only available if the **Multi-Fluid VOF Model** is enabled.
- (optional) selection of **Expert Options** (see Expert Options (p. 1374))

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To specify the number of phases for the multiphase calculation, enter the appropriate value in the **Number of Eulerian Phases** field. You can specify up to 20 phases.

24.2.2. Choosing Volume Fraction Formulation

ANSYS Fluent supports the following options for volume fraction formulation:

Explicit Formulation
The explicit formulation is non-iterative and is time-dependent. Thus it can only be used with the **Transient** solver. It exhibits better numerical accuracy compared to the implicit formulation. However the time step size is limited by a Courant-based stability criterion.

Implicit Formulation
The implicit formulation is iterative and can be used with either the **Steady** or **Transient** solver. It is well-suited to steady-state applications as the solution information propagates much faster compared to the explicit formulation.

For steady-state flow applications, either a steady-state or a transient simulation may be required, depending on the characteristics of the flow:

- *Steady-state simulation*: If the final steady-state solution is not affected by the initial flow conditions and there is a distinct inflow boundary for each phase.
- *Transient simulation*: If the final steady-state solution is dependant on the initial flow conditions and/or you do not have a distinct inflow boundary for each phase.

For transient flow applications, the implicit formulation may allow you to use a much larger time step than the explicit formulation due to the implicit formulation's unconditional stability. However, the implicit time-step size may be limited by truncation errors. The implicit formulation produces more numerical diffusion than the explicit formulation when using the **First Order** transient formulation. Therefore, the implicit formulation should be used along with higher-order transient formulations to achieve better numerical accuracy.

Both implicit and explicit volume fraction formulations are available for the VOF and Eulerian multiphase models. The mixture multiphase model supports only the implicit formulation.

To specify the volume fraction formulation to be used for the VOF and Eulerian multiphase models, select the appropriate **Formulation** under **Volume Fraction Parameters** in the **Multiphase Model** dialog box.

24.2.2.1. Interface Modeling Type

For the VOF model and for the Eulerian Multiphase model with **Multi-Fluid VOF** enabled, you must specify the interface regime that you will be modeling. This will determine the availability of the various volume fraction discretization schemes (Spatial Discretization Schemes for Volume Fraction (p. 1373)). The following options are available for **Interface Modeling Type**:

Sharp
for when a distinct interface is present between the phases

Dispersed
for when the phases are interpenetrating

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Sharp/Dispersed
a hybrid approach for flows consisting of both sharp and dispersed interfaces. This option can also be used to capture mildly sharp interfaces. Mildly sharp interfaces are those that are neither as sharp as would be captured by the schemes available with the **Sharp** option, nor as diffused as would be captured by the schemes available with the **Dispersed** option.

Interfacial Anti-Diffusion

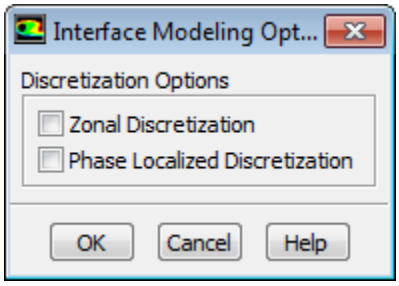
If you are using the Sharp interface modeling type, you can optionally enable the **Interfacial Anti-Diffusion** treatment. This treatment is applied only in interfacial cells and attempts to suppress the numerical diffusion that can arise from the volume fraction advection schemes.

The use of this treatment can have adverse effects on convergence, especially with aggressive settings and large time step size. Therefore, it should be used in cases that use a coarse mesh, that have high aspect-ratio cells, that have large cell-volume jumps in the vicinity of the fluid-fluid interface, or that suffer from excess numerical diffusion.

The strength of the anti-diffusion treatment can be specified using the `define/models/multiphase/interface-modeling-options` text command. The strength can range between `0` (none) and `1` (maximum).

Sharp/Dispersed Interface Modeling Options

Selecting **Sharp/Dispersed** will make available some additional discretization options. To access these, click **Interface Modeling Options...** in the **Multiphase Model** dialog box.



These options allow you to adjust the discretization behavior on a per-zone and/or per-phase-pair basis for cases in which it is important to simultaneously model dispersed and sharp interfaces.

Zonal Discretization
This option is appropriate for applications that require either sharp or dispersed interface modeling depending on the cell zone. After enabling **Zonal Discretization** you will need to specify the slope limiter value on the **Multiphase** tab of the **Fluid** dialog box for each cell zone. (See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391))

Phase Localized Discretization
This option is appropriate for applications that require either sharp or dispersed interface modeling depending on the phase-pair comprising the interface. After enabling **Phase Localized Discretization** you will need to specify the slope limiter values for each phase pair on the **Discretization** tab of the **Phase Interaction** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.2.2.2. Spatial Discretization Schemes for Volume Fraction

You can choose from various spatial discretization schemes for volume fraction depending on the multiphase model in use, the interface regime type, and the volume fraction formulation chosen. The available discretization schemes for each combination off model, formulation, and interface regime are summarized in the following tables:

Table 24.1: Spatial Discretization Schemes for the VOF and Eulerian with Multi-Fluid VOF Models

Interface Modeling Type	Implicit Formulation	Explicit Formulation
Sharp	Compressive BGM (steady state only) Modified HRIC	Geo-Reconstruct CICSAM Compressive Modified HRIC
Sharp/Dispersed	Compressive Modified HRIC	
Dispersed	First Order Upwind Second Order Upwind QUICK	First Order Upwind QUICK

Table 24.2: Spatial Discretization Schemes for the Eulerian Model without Multi-Fluid VOF

Implicit Formulation	Explicit Formulation
First Order Upwind QUICK Modified HRIC	First Order Upwind QUICK Modified HRIC Compressive

Table 24.3: Spatial Discretization Schemes for the Mixture Model

Implicit Formulation	Explicit Formulation
First Order Upwind QUICK	Not Applicable

The **Geo-Reconstruct** scheme is an interface tracking scheme based on geometrical information. It is the most accurate scheme, but is more computationally expensive than the other schemes. **Geo-Reconstruct** is the preferred scheme when solving on meshes of poor quality.

The **CICSAM**, **Modified HRIC**, and **Compressive** schemes are interface capturing schemes based on algebraic information.

The Donor-Acceptor discretization is a scheme applicable only to quad- and hex-meshes. As it is considered obsolete, it does not appear by default in the graphical user interface. However, it can be made available if required using the following text command:

```
/solve/set/expert
<...>
Allow selection of all applicable discretization schemes? [no] yes
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This command can also be used to expose discretization schemes that may be applicable, but are hidden by default according to the tables above.

Important

For the geometric reconstruction and donor-acceptor schemes, if you are using a conformal mesh (that is, if the mesh node locations are identical at the boundaries where two subdomains meet), you must ensure that there are no two-sided (zero-thickness) walls within the domain. If there are, you will need to slit them, as described in Slitting Face Zones (p. 215).

For more details about the implementations of the volume fraction discretization schemes, refer to Interpolation Near the Interface in the *Fluent Theory Guide*.

24.2.2.3. Volume Fraction Limits

The **Volume Fraction Cutoff** allows you to specify a cutoff limit for the volume fraction values. The value that you provide is used as the lower cutoff for the volume fraction. All volume fraction values in the domain below this cutoff value are set to zero. The upper cutoff is calculated as (1.0 - lower cutoff). All volume fraction values above the upper cutoff value are set to 1.0. The default value is 1e-6, which is the recommended value. Using a higher value may lead to a higher volume imbalance.

Important

The **Volume Fraction Cutoff** value can be specified when using the VOF model, or when using the Eulerian Multiphase model with the **Explicit** formulation.

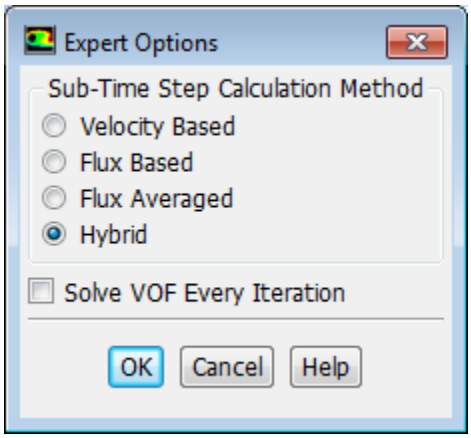
Note

For the **Implicit** formulation, the minimum value allowed is 0 and the maximum allowable value is 1e-6. For the **Explicit** formulation, the minimum value allowed is 0 and the maximum allowable value is 1e-4. A higher cutoff value is available with the **Explicit** formulation because it allows for the local redistribution procedure of partially filled cells, which accounts for volume loss. This treatment is not available with the **Implicit** formulation.

24.2.2.4. Expert Options

When using the **Explicit** formulation, there are several additional options that you can access by clicking **Expert Options...** in the **Multiphase Model** dialog box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Sub-Time Step Calculation Method

This setting controls how the time-scale is computed when determining the time step used for volume fraction.

Solve VOF Every Iteration

This setting controls whether to solve the volume fraction equations once per iteration, or only once per time step.

For a more detailed discussion of how to use these options, refer to Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation (p. 1445).

24.2.3. Solving a Homogeneous Multiphase Flow

If you are using the mixture model, you have the option to disable the calculation of slip velocities and solve a homogeneous multiphase flow (that is, one in which the phases all move at the same velocity). By default, ANSYS Fluent will compute the slip velocities for the secondary phases, as described in Relative (Slip) Velocity and the Drift Velocity in the Theory Guide. If you want to solve a homogeneous multiphase flow, turn off **Slip Velocity** under **Mixture Parameters**.

24.2.4. The Boussinesq Approximation in Multiphase Flow

When using the Boussinesq approximation for density variation in multiphase flows, there are several important items to consider:

- The Boussinesq approximation is only valid for small variations in fluid densities caused by small variations in temperature. Therefore, constant density is assumed, and a momentum source is only added for modeling buoyancy.
- The Boussinesq approximation assumes that small density variations have little effect on inertial terms and strong effects on gravitational terms. Thus, the differences in specific weights between two fluids or layers of fluids is the force driving the flow. (Waves cannot use this approximation.) Two non-dimensional numbers quantify the effect of buoyancy: the Richardson number and the Rayleigh number.
- Operating density should be set to zero.

For additional information on the Boussinesq approximation, see The Boussinesq Model (p. 833).

24.2.5. Modeling Compressible Flows

If you are using any of the multiphase models for a compressible flow, note the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- ANSYS Fluent allows the modeling of:
  - Multiple compressible ideal gas phases and/or incompressible/compressible liquids at any inlet
  - A single real gas or real liquid at any inlet
  - Multiple real gases at a single inlet
  - Multiple compressible liquids using either the Fluent built-in compressible liquid density model based on the Tait law (see Compressible Liquid Density Method (p. 480)) or user-defined functions

  For multiple compressible phases, the fundamental equations for compressible flow remain the same. However, boundary conditions are modified to account for changes in material properties due to compressible fluid mixtures.
- In cases of a mixture of ideal and real gases, the phases must enter the domain through separate inlets.
- When using the VOF model, stability is improved if the primary phase is the compressible ideal gas.
- If you specify the total pressure at a boundary (for example, for a pressure inlet or intake fan), Fluent will use the specified value for temperature at that boundary as total temperature for the compressible phase, and as static temperature for the other phases (which are incompressible).
- For each mass flow inlet, you will need to specify mass flow or mass flux for each individual phase.

Important

Note that if you read a case file that was set up in a version of Fluent previous to 6.1, you will need to redefine the conditions at the mass flow inlets. See Defining Multiphase Cell Zone and Boundary Conditions (p. 1391) for more information on defining conditions for a mass flow inlet in multiphase calculations.

Enhanced Compressible Flow Numerics

Compressible flow simulations may have convergence difficulties due to explicit handling of source term accounting for density variation. These simulations could become extremely unstable in the presence of a large variation in pressure and temperature. In ANSYS Fluent, an enhanced numerical treatment that provides better stability at startup and during calculation of compressible flows is enabled by default. The treatment controls the rate of change of pressure and temperature between iterations and provides additional diagonal dominance to the matrix of equations.

Although disabling the enhanced numerical treatment is not recommended, you can temporarily turn it off to investigate unstable cases using the following text user interface command:

```
solve/set/multiphase-numerics/compressible-flow/enhanced-numerics
...
enhanced compressible flow numerics? [yes] no
```

See Compressible Flows (p. 593) for more information about compressible flows.

Alternative Compressible Flow Numerics

A more general formulation for compressible multiphase flows employs a mathematically rigorous treatment of compressible phases at an inlet boundary. Instead of treating the entering incompressible

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

and compressible phases as a pseudo-mixture, this formulation calculates static temperature and pressure using an iterative method based on fundamental thermodynamic relations (such as the Maxwell relations). This approach involves evaluation of the property derivatives, which can be computed either numerically or through analytic expressions. You can enable this alternative treatment via the text command:

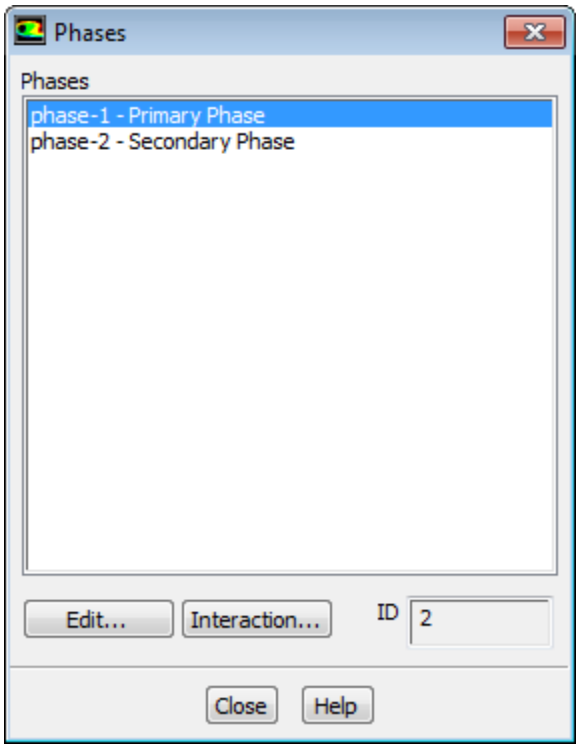
```
solve/set/multiphase-numerics/compressible-flow/alternate-bc-formulation
alternate compressible bc formulation? [no] y
use analytical thermodynamic derivatives? [no] y
```

24.2.6. Defining the Phases

To define the phases (including their material properties) and any interphase interaction (for example, surface tension and wall adhesion for the VOF model, slip velocity for the mixture model, drag functions for the mixture and the Eulerian models), (Figure 24.4: The Phases Dialog Box (p. 1377)).

Setup → Models → Multiphase → Phases Edit...

Figure 24.4: The Phases Dialog Box



Each item in the **Phases** list in this dialog box is one of two types: a **Primary-Phase** indicates that the selected item is the primary phase, and **Secondary-Phase** indicates that the selected item is a secondary phase. To specify any interaction between the phases, click the **Interaction...** button.

Instructions for defining the phases and interaction are provided in Defining the Phases for the VOF Model (p. 1436), Defining the Phases for the Mixture Model (p. 1447), and Defining the Phases for the Eulerian Model (p. 1456) for the VOF, mixture, and Eulerian models, respectively.

24.2.7. Including Body Forces

When large body forces (for example, gravity or surface tension forces) exist in multiphase flows, the body force and pressure gradient terms in the momentum equation are almost in equilibrium while

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the contributions of convective and viscous terms are small in comparison. Segregated algorithms converge poorly unless partial equilibrium of pressure gradient and body forces is taken into account. ANSYS Fluent provides an optional "implicit body force" treatment that can account for this effect, making the solution more robust.

The basic procedure involves augmenting the correction equation for the face flow rate, Equation 21.51 in the Theory Guide, with an additional term involving corrections to the body force. This results in extra body force correction terms in Equation 21.49 in the Theory Guide, and allows the flow to achieve a realistic pressure field very early in the iterative process.

To include this body force, enable **Gravity** in the Operating Conditions Dialog Box (p. 2382) and specify the **Gravitational Acceleration**.

Setup → **Cell Zone Conditions** → **Operating Conditions...**

For VOF calculations, you should also enable the **Specified Operating Density** option in the **Operating Conditions** dialog box, and set the **Operating Density** to be the density of the lightest phase. (This excludes the buildup of hydrostatic pressure within the lightest phase, improving the round-off accuracy for the momentum balance.) If any of the phases is compressible, set the **Operating Density** to zero.

Important

For VOF and mixture calculations involving body forces, it is recommended that you also enable the **Implicit Body Force** treatment for the **Body Force Formulation** in the **Multiphase Model** dialog box. This treatment improves solution convergence by accounting for the partial equilibrium of the pressure gradient and body forces in the momentum equations. See Including Body Forces (p. 1377) for details.

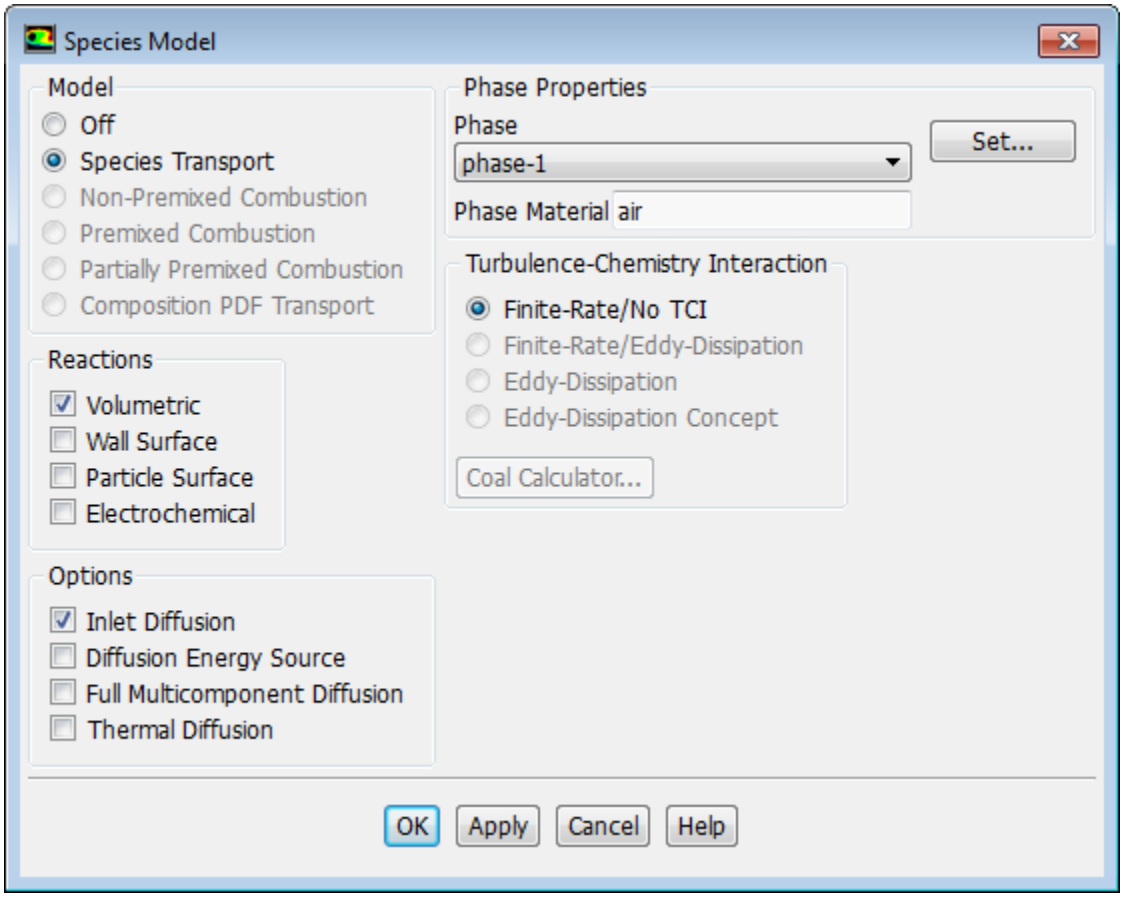
24.2.8. Modeling Multiphase Species Transport

ANSYS Fluent lets you describe a multiphase species transport and volumetric reaction (Modeling Species Transport in Multiphase Flows in the Theory Guide) in a fashion that is similar to setting up a single-phase chemical reaction using the **Species Model** dialog box (for example, Figure 24.5: The Species Model Dialog Box with a Multiphase Model Enabled (p. 1379)).

Setup → **Models** → **Species** → **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

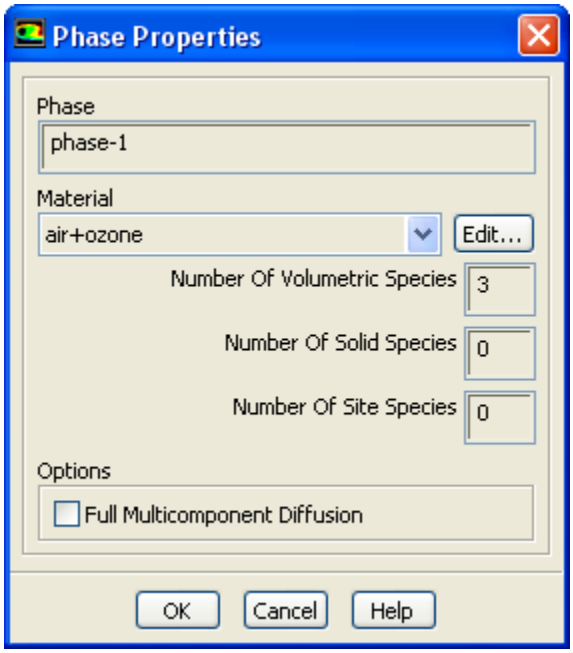
Figure 24.5: The Species Model Dialog Box with a Multiphase Model Enabled



1. Select **Species Transport** under **Model**.
2. Enable **Volumetric** under **Reactions**.
3. Select a specific phase using the **Phase** drop-down list under **Phase Properties**.
4. Click the **Set...** button to display the **Phase Properties** dialog box (Figure 24.6: The Phase Properties Dialog Box (p. 1380)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.6: The Phase Properties Dialog Box



In the **Phase Properties** dialog box, the material for each phase is listed in the **Material** drop-down list. From this list, you can choose the material that you want to use for a specific phase. The drop-down list contains all of the materials, then open the **Edit Material** dialog box by clicking the **Edit...** (or **View...**) button next to the **Material** drop-down list.

5. In the **Species Model** dialog box, choose the **Turbulence-Chemistry Interaction** model. Three models are available:

   Laminar Finite-Rate
   computes only the Arrhenius rate (see Equation 7.7 in the Theory Guide) and neglects turbulence-chemistry interaction.

   Eddy-Dissipation
   (for turbulent flows) computes only the mixing rate (see Equation 7.25 and Equation 7.26 in the Theory Guide).

   Finite-Rate/Eddy-Dissipation
   (for turbulent flows) computes both the Arrhenius rate and the mixing rate and uses the smaller of the two.

When modeling multiphase species transport, additional inputs may also be required depending on your modeling needs. See, for example, Specifying Heterogeneous Reactions (p. 1380) for more information defining heterogeneous reactions, or Including Mass Transfer Effects (p. 1383) for more information on mass transfer effects.

24.2.9. Specifying Heterogeneous Reactions

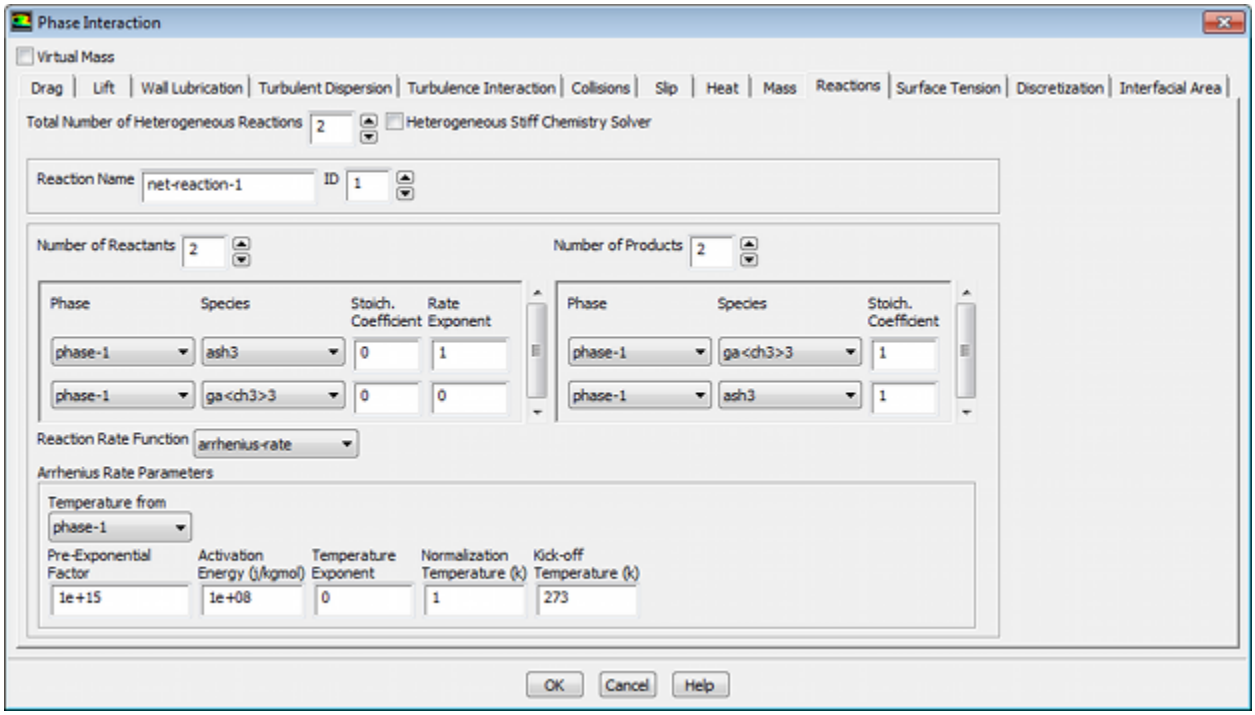
You can use ANSYS Fluent to define multiple heterogeneous reactions and stoichiometry using the **Phase Interaction** dialog box (for example, Figure 24.7: The Phase Interaction Dialog Box for Heterogeneous Reactions (p. 1381)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Multiphase → Phases → Edit... → Interaction...

1. In the **Phases** dialog box (Figure 24.4: The Phases Dialog Box (p. 1377)), click the **Interaction...** button to open the **Phase Interaction** dialog box.

   Figure 24.7: The Phase Interaction Dialog Box for Heterogeneous Reactions



2. Click the **Reactions** tab in the **Phase Interaction** dialog box.

3. Set the total number of reactions (volumetric reactions, wall surface reactions, and particle surface reactions) in the **Total Number of Heterogeneous Reactions** field. (Use the arrows to change the value, or type in the value and press **Enter**.)

4. Enable the **Heterogeneous Stiff Chemistry Solver** option if your inter-phase reaction mechanism contains numerically stiff reactions. This option can improve convergence and is available for transient Eulerian multiphase simulations. When this option is enabled, ANSYS Fluent uses a fractional step algorithm where the flow is advanced without reaction sources for a time step, and then the chemistry is integrated point-by-point for the same time step. The stiff chemistry scheme solves all species in all phases coupled. Note that it is possible to include homogeneous (intra-phase) reactions along with the heterogeneous reactions in the **(Phase Interaction** dialog box (instead of in the reaction mechanism in the **Create/Edit Materials** dialog box), and these reactions will be solved with the stiff solver. The stiff ODE solver tolerances can be set using the following text command:

   `solve → set → heterogeneous-stiff-chemistry`

5. Specify the **Reaction Name** of each reaction that you want to define.

6. Set the **ID** of each reaction you want to define. (Again, if you type in the value be sure to press **Enter**.)

7. For each reaction, specify how many reactants and products are involved in the reaction by increasing the value of the **Number of Reactants** and the **Number of Products**. Select each reactant or product in the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Reaction tab and then set its stoichiometric coefficient in the **Stoich. Coefficient** field. (The stoichiometric coefficient is the constant $\nu'_{i,r}$ or $\nu''_{i,r}$ in Equation 7.6 in the Theory Guide.)

8. For each reaction, indicate the **Phase** and **Species** and the stoichiometric coefficient for each of your reactants and products.

9. For each reaction, use the **Reaction Rate Function** drop-down list to select one of the following:

none
if you do not want to include a reaction rate

population-balance
is the mass transfer due to nucleation and growth. If neither the primary phase or secondary phase has species associated with it, then the mass transfer is modeled as unidirectional. If the mass transfer process involves reactions or species, the problem must be set up as one involving heterogeneous reaction/mass transfer.

Important

The **population-balance** option for **Reaction Rate Function** should not be used if there are multiple reactions leading to the formation of the secondary phase. In this case, the reaction rate functions should be specified either through the standard dialog boxes or user-defined functions and the growth rate function should be a sum of the individual reaction rates. This would ensure consistency between the individual reaction rates and the total mass transfer from the primary to the secondary phase.

You can always use `DEFINE_MASS_TRANSFER` or `DEFINE_HET_RXN_RATE` user-defined function types instead of the **population-balance** option to specify mass transfer rates. However, the growth rate function and the mass transfer rates returned from the UDFs need to be consistent with each other.

arrhenius-rate
to specify rate exponents for an Arrhenius-type reaction (see Heterogeneous Phase Interaction in the Theory Guide for more information)

Important

This simple form of the Arrhenius rate option may only be used for devolatilization reactions only. Char combustion reaction may be more involved and complicated to be simply casted in this form. Additional diffusion rate formulations may be needed to formulate a complete char (or solid phase) reaction system.

Important

Note that you can also specify the heterogeneous reaction rates using a user-defined function. A user-defined function is available for an Arrhenius-type reaction with rate

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

exponents that are equivalent to the stoichiometric coefficients. For more information, see DEFINE_HET_RXN_RATE in the Fluent Customization Manual.

Important

ANSYS Fluent assumes that the reactants are mixed thoroughly *before* reacting together, therefore the heat and momentum transfer is based on this assumption. This assumption can be disabled using a text command. For more information, contact your ANSYS Fluent support engineer.

24.2.10. Including Mass Transfer Effects

As discussed in Modeling Mass Transfer in Multiphase Flows in the Theory Guide, mass transfer effects in the framework of ANSYS Fluent's general multiphase models (that is, Eulerian multiphase, mixture multiphase, or VOF multiphase) can be modeled in one of three ways:

- Unidirectional constant rate mass transfer (not available for VOF calculations)
- UDF-prescribed mass transfer
- mass transfer through cavitation, evaporation-condensation, boiling, or generalized species mass transfer

Because of the different procedures and limitations involved, defining mass transfer through the Singhal et al. cavitation model is described separately in Including Cavitation Effects (p. 1455).

Note

There are limitations and recommendations specific to using cavitation with the VOF model. See Limitations of Cavitation with the VOF Model in the *Fluent Theory Guide* for additional information.

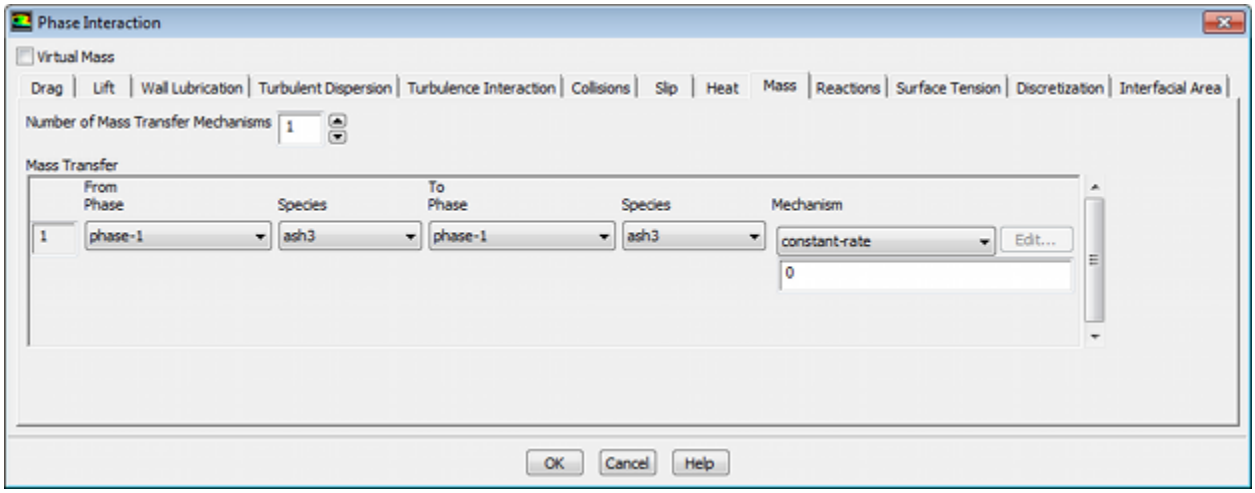
For general limitations regarding the cavitation models, see Limitations of the Cavitation Models in the *Fluent Theory Guide*.

To define mass transfer in a multiphase simulation as a unidirectional constant, using a user-defined function, through population balance, cavitation, evaporation/condensation, or species mass transfer you will need to use the **Phase Interaction** dialog box (for example, Figure 24.8: The Phase Interaction Dialog Box for Mass Transfer (p. 1384)).

Setup → **Models** → **Multiphase** → **Phases** → **Edit...** → **Interaction...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.8: The Phase Interaction Dialog Box for Mass Transfer



1. Click the **Mass** tab in the **Phase Interaction** dialog box.

2. Specify the **Number of Mass Transfer Mechanisms**.

   Important

   In general, you should use only one mass transfer mechanism when you employ one of the available mass transfer models (see Step 7). Although using multiple mass transfer mechanisms is allowed for any pairs of phases (including the same pair of phases), it is not recommended because the mass transfer models have been fundamentally developed for a single mass transfer process. These models do not account for possible interactions between two mass transfer mechanisms in a flow system. In order to account for all relevant physics using UDFs in multiple mass transfer mechanisms, you can use the user-defined option. For additional restrictions when using multiple mass transfer mechanisms, see Step 7.

3. For each mechanism, specify the phase of the source material under **From Phase**. Note that the phase you select for **From Phase** must be a liquid if you plan to select **cavitation**, **evaporation-condensation**, or **boiling** from the **Mechanism** drop-down menu (see Step 7).

4. If species transport is part of the simulation, and the source phase is composed of a mixture material, then specify the species of the source phase mixture material in the corresponding **Species** drop-down list.

5. For each mechanism, specify the phase of the destination material phase under **To Phase**. Note that the phase you select for **To Phase** must be a vapor if you plan to select **cavitation**, **evaporation-condensation**, or **boiling** from the **Mechanism** drop-down menu. If you plan to select **species-mass-transfer** and one of the phases is a gas, it must be specified as the **To Phase** (see Step 7).

6. If species transport is part of the simulation, and the destination phase is composed of a mixture material, then specify the species of the destination phase mixture material in the corresponding **Species** drop-down list.

7. For each pair of phases with mass transfer, select the desired mass transfer mechanism under **Mechanism**. The available mechanisms and their inputs are described in Mass Transfer Mechanisms (p. 1385).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ANSYS Fluent will automatically include the terms needed to model mass transfer in all relevant conservation equations. Another option to model mass transfer between phases is through the use of user-defined sources and their inclusion in the relevant conservation equations. This approach is more involved, but more powerful, allowing you to split the source terms according to a model of your choice.

Important

- Except for the **species-mass-transfer** mechanism, if the same mass transfer model is selected for multiple mass transfer mechanisms, the most recently edited mechanism sub-model, including its parameters, options, and constants (excluding its material properties, such as vaporization pressure or saturation temperature), will apply to all the mass transfer mechanisms.
- When modeling multiple **species-mass-transfer** mechanisms, you can select different species mass transfer models and model options, such as Raoult's Law, Henry's Law, etc. However, because there is a lack of interaction between different species mass transfer models, this should be done with caution. For information on modeling restrictions for interphase species mass transfer, see Interphase Species Mass Transfer in the *Fluent Theory Guide*.
- Momentum, energy, and turbulence are also transported with the mass that is transferred. ANSYS Fluent assumes that the reactants are mixed thoroughly *before* reacting together, therefore the heat and momentum transfer is based on this assumption. This assumption can be disabled using a text command. For more information, contact your ANSYS Fluent support engineer.

When your model involves the transport of multiphase species, you can define a mass transfer mechanism between species from different phases. If a particular phase does not have a species associated with it, then the mass transfer throughout the system will be performed by the bulk fluid material.

Important

Including species transport effects in the mass transport of multiphase simulation requires that **Species Transport** be selected in the **Species Model** dialog box.

Setup → **Models** → **Species**

24.2.10.1. Mass Transfer Mechanisms

When including mass transfer effects in a multiphase simulation, you can choose from the following mechanisms for each phase pair that undergoes mass transfer.

constant-rate
enables a user-specified constant, unidirectional mass transfer. The **constant-rate** must be entered in units of 1/time unit.

user-defined
allows you to implement a correlation reflecting a model of your choice, through a user-defined function.

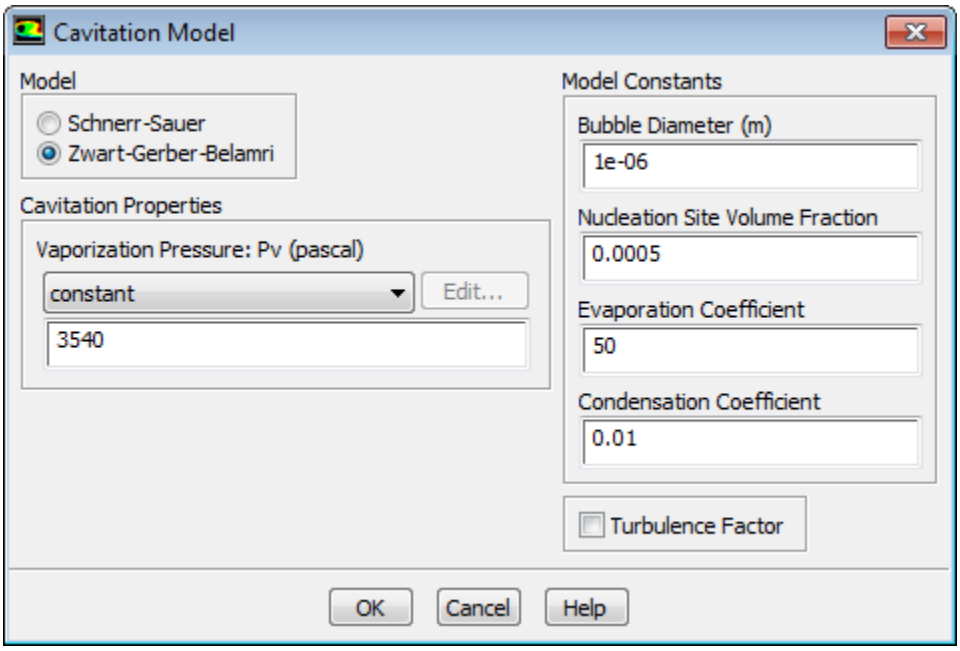
population-balance
allows you to model flow where a number density function is introduced to account for the particle population. With the aid of particle properties (for example, particle size, porosity, composition, and so on),

different particles in the population can be distinguished and their behavior can be described. For a comprehensive understanding of this option, refer to the Population Balance Module Manual.

cavitation

allows you to select a cavitation model. The cavitation models are available when using mixture, VOF, and Eulerian multiphase models. You are provided with two model options: **Schnerr-Sauer** and **Zwart-Gerber-Belamri**. To open the **Cavitation Model** dialog box, select **cavitation** from the **Mechanism** drop-down list. For information about the cavitation models, refer to Cavitation Models in the Theory Guide.

Figure 24.9: The Cavitation Model Dialog Box



Note

If multiple phase pairs have the **cavitation** mechanism selected, the same settings in the **Cavitation Model** dialog box will be used for all phase pairs.

- For the **Schnerr-Sauer** model, specify the **Bubble Number Density** under **Model Constants**.
- For the **Zwart-Gerber-Belamri** model, specify the **Bubble Diameter**, the **Nucleation Site Volume Fraction**, the **Evaporation Coefficient**, and the **Condensation Coefficient** under **Model Constants**.

Note

It is advisable to use the default values for all the model constants in both the **Schnerr-Sauer** and **Zwart-Gerber-Belamri** models.

- Under **Cavitation Properties**, specify the **Vaporization Pressure** and, if desired, a temperature dependence function. In addition to the methods described in Defining Properties Using Temperature-Dependent Functions (p. 475) (**constant**, **polynomial**, **piecewise-linear**, **piecewise-polynomial**, or **user-defined**) you can choose **taylor-approximation**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The **taylor-approximation** method models the vaporization pressure as linearly varying with temperature about the free-stream value. This approach can improve numerical stability, but is only appropriate when deviations about the free-stream temperature are sufficiently small that higher-order terms can be neglected. The expression for the vaporization pressure using the **taylor-approximation** method is:

$$P_v = P_v(T_\infty) + C_{thermal} \frac{\rho_l(T_\infty)\rho_v(T_\infty)L(T_\infty)}{T_\infty\left[\rho_l(T_\infty) - \rho_v(T_\infty)\right]}(T - T_\infty) \tag{24.1}$$

where T_∞ is the free-stream temperature, L is the latent heat, and $C_{thermal}$ is a user-modifiable coefficient. In the **Taylor Approximation** dialog box, you will specify **Vaporization Pressure** (at the free-stream temperature), **Free Stream Temperature**, and **Thermal Coefficient** ($C_{thermal}$).

- If you want to include the influence of turbulence on the threshold cavitation pressure, enable **Turbulence Factor**. If desired, you can adjust the value of the **Turbulent Coefficient**. For details about the implementation of the Turbulence Factor, see Turbulence Factor in the *Fluent Theory Guide*.

Note

If the **Mixture** multiphase model is enabled, then the Singhal et al. cavitation model can be enabled using the `solve/set/expert` text command and responding `yes` to `use Singhal-et-al cavitation model?`. The **Singhal-Et-Al Cavitation Model** option will now be visible in the **Phase Interaction** dialog box, under the **Mass** tab. Enable this option to include the Singhal et al. cavitation model. Refer to Including Cavitation Effects (p. 1455) for information about setting the cavitation parameters. Also refer to Cavitation Models in the Theory Guide for information about the Singhal et al. model.

To disable this model, first deselect the **Singhal-Et-Al Cavitation Model** option in the **Phase Interaction** dialog box, then type the `solve/set/expert` text command again and enter `no` when asked if you want to `use Singhal-et-al cavitation model?`

---

evaporation-condensation

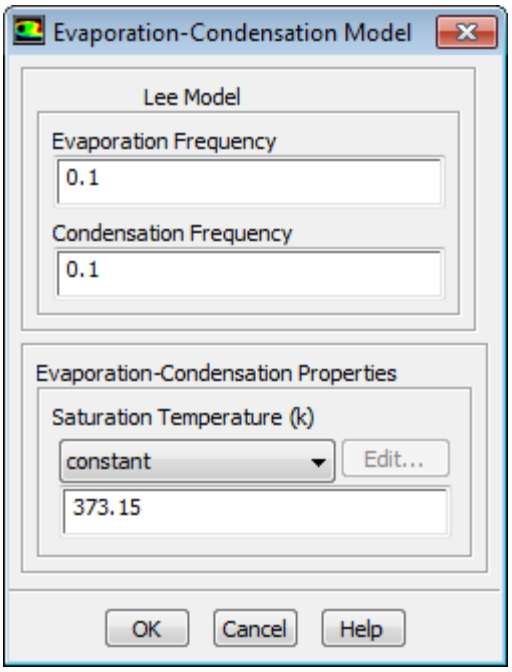
enables you to apply the evaporation-condensation model as the mass transfer mechanism. This model is available with the mixture, VOF, and Eulerian multiphase models. Refer to Evaporation-Condensation Model in the Theory Guide for a theoretical discussion about this model.

Note

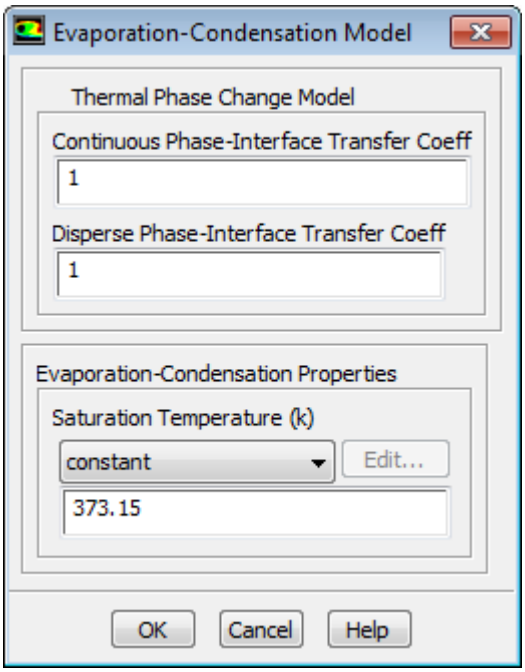
- If multiple phase pairs have the **evaporation-condensation** mechanism selected, the same settings in the **Evaporation-Condensation Model** dialog box will be used for all phase pairs.
- If you are using the **evaporation-condensation** mass transfer mechanism with VOF it is recommended that you use one of the diffusive interface capturing discretization schemes for volume fraction, such as **QUICK**, **HRIC**, or **Phase Localized Compressive** (Discretizing Using the Phase Localized Compressive Scheme (p. 1443)).

- If you are using the mixture or VOF multiphase formulation, or if you have selected the **Lee Model** in the Eulerian formulation, you will need to enter the **Evaporation Frequency** and **Condensation Frequency** model constants. These values correspond to the coefficient $coeff$ (Equation 17.513 in the Theory Guide). The values are `0.1` by default. However, note that the bubble diameter and accommodation coefficient are usually not very well known, so the appropriate values for a given problem can be very different. It is important that the values be tuned to match experimental data.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



- If you are using the Eulerian multiphase formulation and have selected the **Thermal Phase Change** model, enter the **Continuous Phase–Interface Transfer Coeff** and **Dispersed Phase–Interface Transfer Coeff**. If you are using the two-resistance option for heat transfer, these values act as multipliers for the phase heat transfer coefficients determined for each phase and the default value of 1 is usually appropriate. If you are using one of the other heat transfer options, then these parameters correspond to the coefficient $coeff$ (Equation 17.513 in the Theory Guide) and should be tuned based on experimental data.



- Specify the **Saturation Temperature** for your flow regime.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

species-mass-transfer

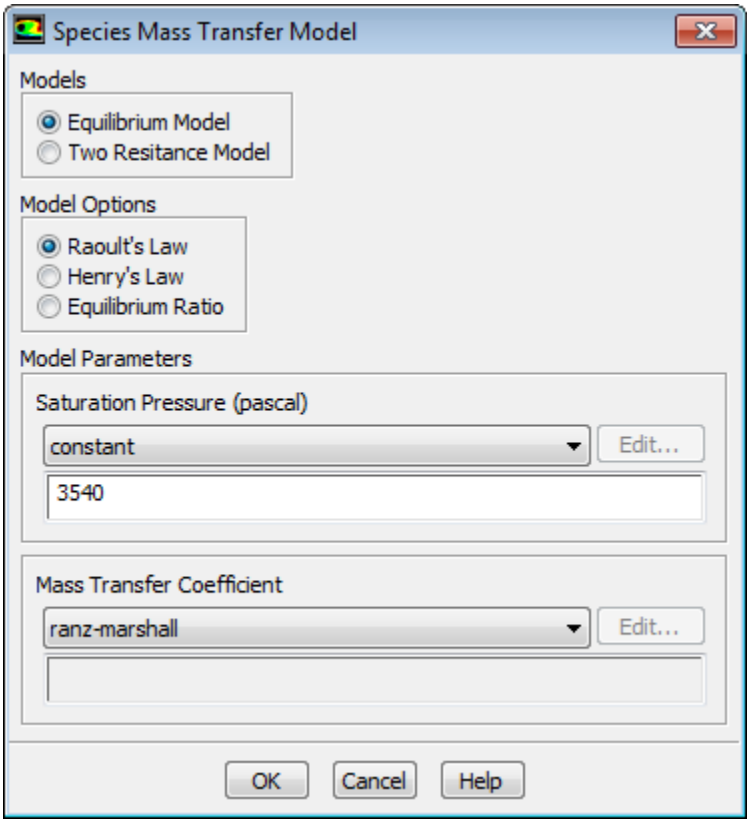
enables you to model generalized interphase species mass transfer in either the Mixture model (when Slip Velocity is enabled) or the Eulerian model subject to the following conditions:

- Both phases consist of mixtures with at least two species, and at least one of species is present in both phases.
- The two mixture phases are in contact and separated by an interface.
- Species mass transfer can only occur between the same species from one phase to the other. For example, evaporation/condensation between water liquid and water vapor.
- As in all interphase mass transfer models in Fluent, if a gas mixture is involved in an interphase species mass transfer process, it is always treated as a **To Phase** and the liquid mixture as a **From Phase**.
- For the species involved in the mass transfer, the mass fractions in both phases must be determined by solving transport equations. For example, the mass fractions of water liquid and water vapor in an evaporation/condensation case must be solved directly from the governing equations, rather than algebraically or from the physical constraint relations.

When you select **species-mass-transfer** under **Mechanism** in the Phase Interactions dialog box, you will be prompted with the **Species Mass Transfer Model** dialog box.

Note

If multiple phase pairs have the **species-mass-transfer** mechanism selected, the same settings in the **Species Mass Transfer Model** dialog box will be used for all phase pairs.



The steps to configure the species mass transfer model are as follows:

1. Under **Models** select either the **Equilibrium Model** or the **Two-Resistance Model**.

   Equilibrium Model
   models the species mass transfer based on equilibrium between the bulk phases.

   Two-Resistance Model
   models the species mass transfer based on equilibrium at the phase interface.

2. Under **Model Options**, choose the sub-model for determining the dynamic equilibrium relations between the same species in a pair of phases.

   Raoult's Law
   Use Raoult's Law as described in Raoult's Law in the *Fluent Theory Guide*. This model is appropriate for gas-liquid cases in which the liquid phase can be modeled as an ideal liquid mixture. If you use Raoult's Law, you must specify the saturation pressure as a constant, polynomial, piecewise-linear, piece-wise polynomial, or as a user-defined function using the `DEFINE_PROPERTY` macro.

   Henry's Law
   Use Henry's Law as described in Henry's Law in the *Fluent Theory Guide*. This model is appropriate for cases in which a gas species is dissolved into a non-ideal liquid mixture phase. If you use Henry's Law you must specify the method for the **Molar Fraction Henry Coeff** or **Molar Concentration Henry Coeff**. You can choose a constant, **vant-hoff** (to use the Van't Hoff correlation), or a user-defined function using the `DEFINE_MASS_TRANSFER` macro. For the **vant-hoff** model, you will need to specify **Reference Henry Constant** (K_H^0 in Equation 17.540 in the *Fluent Theory Guide*) and **Temperature Dependence** ($\frac{\Delta_{soln}H}{R}$) in the **Vant Hoff's Correlation** dialog box.

   Equilibrium Ratio
   Use the Equilibrium Ratio method as described in Equilibrium Ratio in the *Fluent Theory Guide*. This model allows you to specify the equilibrium ratio as a constant, or as a user-defined function. If you use **Equilibrium Ratio** you must specify a constant or user-defined function using the `DEFINE_MASS_TRANSFER` macro for **Molar Fraction Equilibrium Ratio**, **Molar Concentration Equilibrium Ratio**, or **Mass Fraction Equilibrium Ratio**.

3. Choose the sub-model for determining the **Mass Transfer Coefficient**. If you are using the Two Resistance Model, you will need to specify sub-models for both **Continuous-Interface Mass Transfer Coeff.** and **Dispersed-Interface Mass Transfer Coeff.**.

   constant
   Specify a constant value for the mass transfer coefficient.

   sherwood-number
   Specify a constant value for the Sherwood Number. The mass transfer coefficient is calculated from Equation 17.543 in the *Fluent Theory Guide*.

   ranz-marshall
   Use the Ranz-Marshall model as described in Ranz-Marshall Model in the *Fluent Theory Guide*. The Ranz-Marshall model is based on boundary layer theory for steady flow past a spherical particle. It is applicable under the following flow conditions:

$$0 \le \mathrm{Re}_q < 200$$
$$0 \le \mathrm{Sc}_q < 250$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

hughmark
Use the Hughmark model as described in Hughmark Model in the *Fluent Theory Guide*. The Hughmark model extends the Ranz-Marshall model for a wider range of relative Reynolds number, Re_q.

zero-resistance
Specify zero-resistance mass transfer between the bulk phase and interface (available only for the Two-Resistance model).

user-defined
Use a user-defined function for the mass transfer coefficient defined with the `DEFINE_MASS_TRANSFER` macro.

When using the Two-Resistance model, the selection of physically correct mass transfer correlations is highly problem dependent. In the case of mass transfer between a continuous phase and a dispersed phase of approximately spherical particles, the following should be adequate under most situations:

- **ranz-marshall** or **hughmark** for the continuous phase
- **zero-resistance** for the dispersed phase

Using zero-resistance for the dispersed phase implies that the mass transfer occurs very quickly from the interface to the bulk of the dispersed phase. Consequently the interface concentration and bulk concentration in the dispersed phase are equal. This is usually valid for droplet evaporation or gas absorption/dissolution in bubbles. If there exists significant resistance to the mass transfer on the dispersed phase side, one of the other correlations should be chosen for the dispersed phase.

boiling
enables you to apply the boiling model as the mass transfer mechanism. This model is only available with the Eulerian multiphase model (when **Boiling** is enabled in the **Multiphase Model** dialog box). For information about the inputs in Figure 24.62: The Boiling Model Dialog Box (p. 1490), refer to Including the Boiling Model (p. 1486).

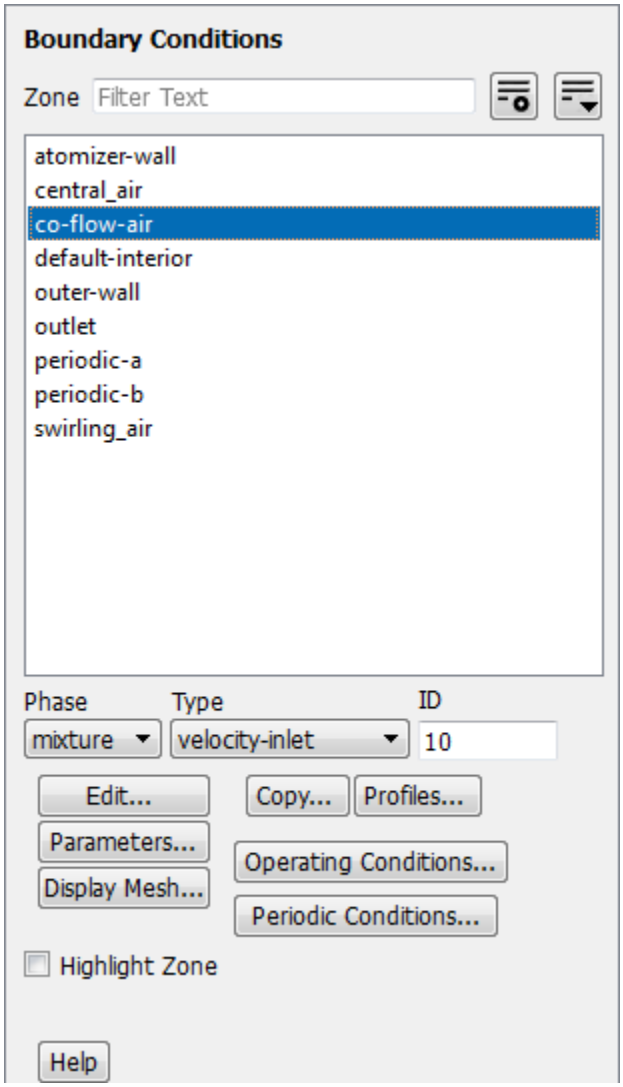
24.2.11. Defining Multiphase Cell Zone and Boundary Conditions

The procedure for setting multiphase cell and boundary conditions is slightly different than for single-phase models. You will need to set some conditions separately for individual phases, while other conditions are shared by all phases (that is, the mixture), as described in Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398).

24.2.11.1. Steps for Setting Boundary Conditions

Setup → Boundary Conditions

Figure 24.10: The Boundary Conditions Task Page



The steps you need to perform for each boundary are as follows:

1. Select the boundary in the **Zone** list in the **Boundary Conditions** task page.

2. Set the conditions for the mixture at this boundary, if necessary. (For information about which conditions need to be set for the mixture, refer to Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398).)

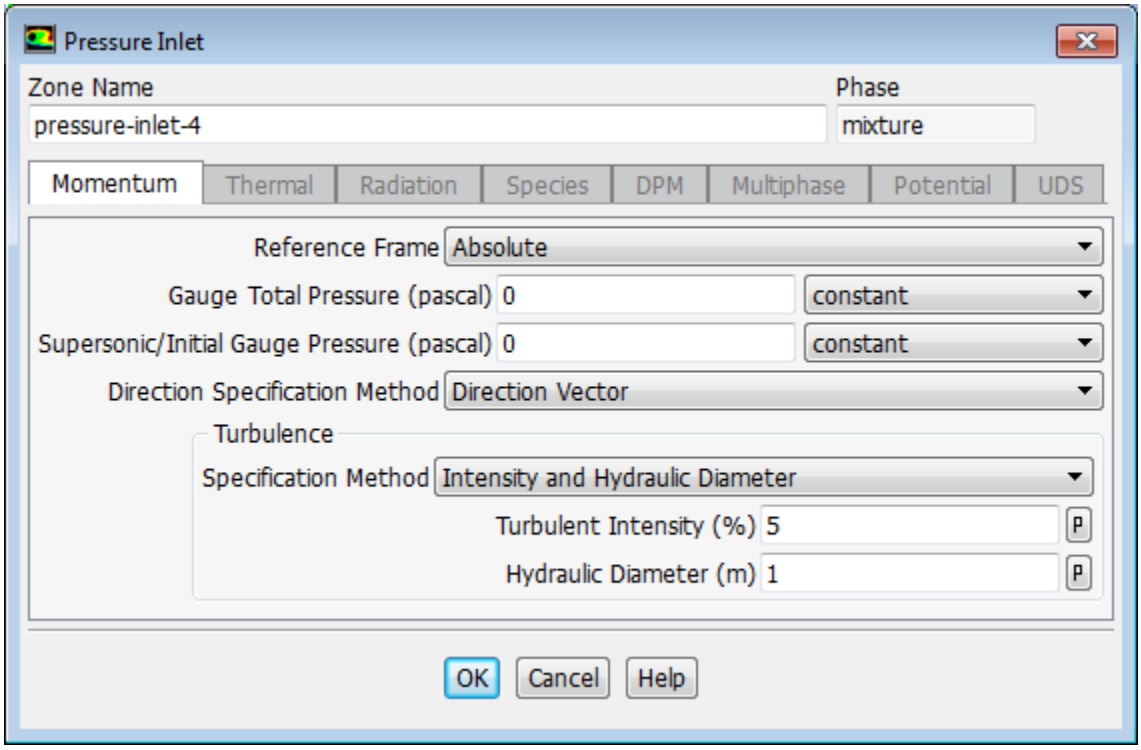
   a. In the **Phase** drop-down list, select **mixture**.

   b. If the current **Type** for this zone is correct, click **Edit...** to open the corresponding boundary condition dialog box (for example, the **Pressure Inlet** dialog box); otherwise, choose the correct zone type in the **Type** drop-down list, confirm the change (when prompted), and the corresponding dialog box will open automatically.

   c. In the boundary condition dialog box for the selected zone type (for example, the **Pressure Inlet** dialog box for the Eulerian model, shown in Figure 24.11: The Pressure Inlet Dialog Box for a Mixture (p. 1393)), specify the mixture boundary conditions.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.11: The Pressure Inlet Dialog Box for a Mixture



Note that only those conditions that apply to all phases, as described in Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398), will appear in this dialog box.

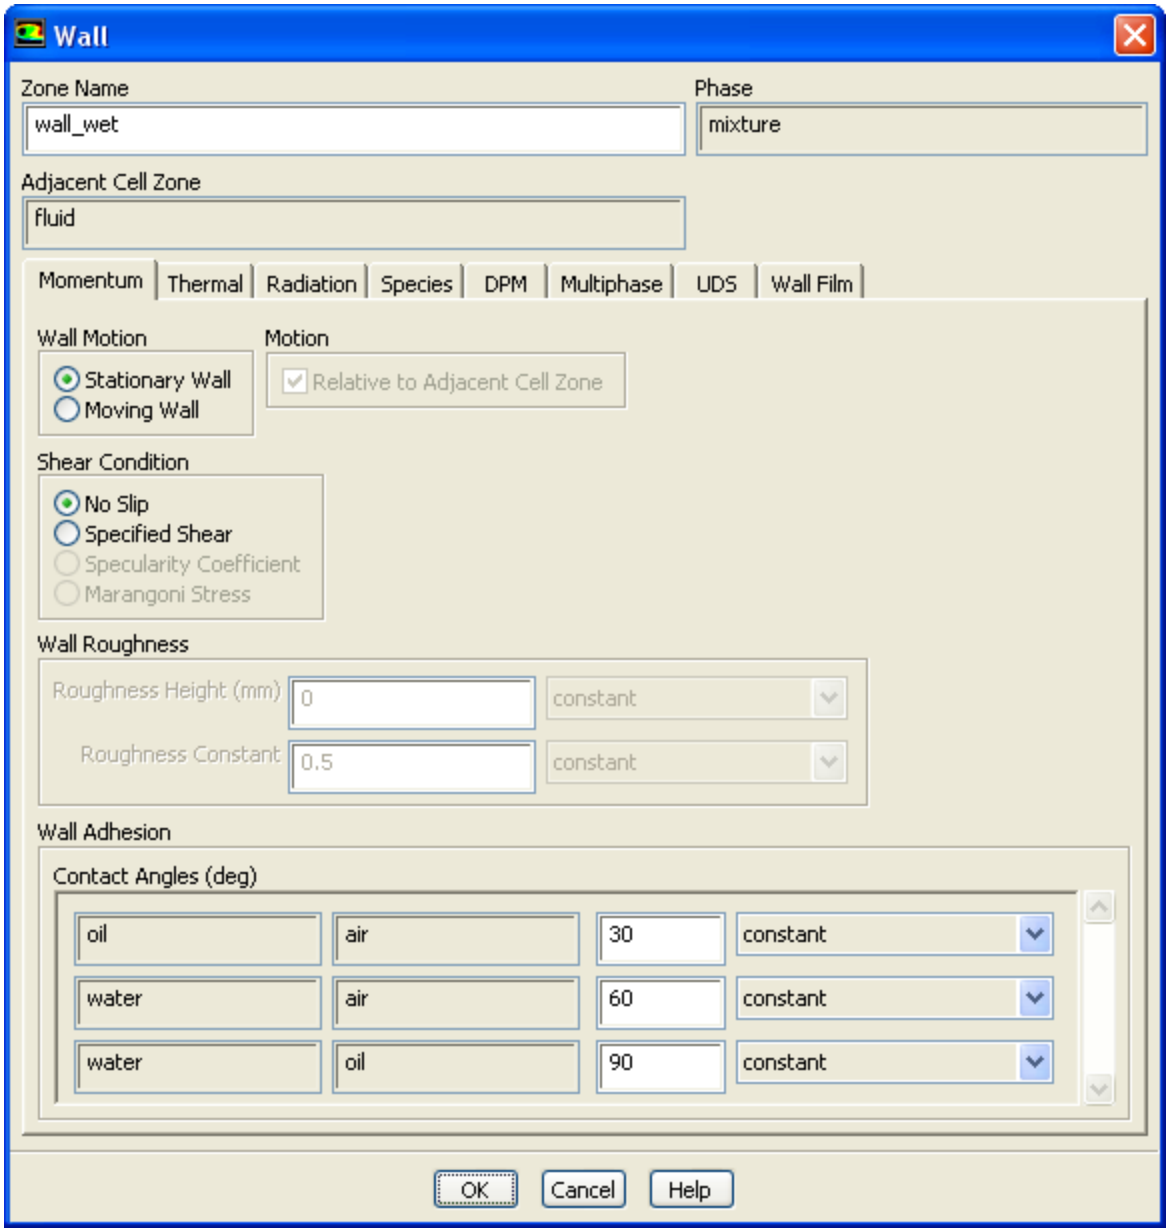
For information about inputs related to the relevant boundary conditions, refer to the appropriate sections for those boundary conditions.

d. Define additional boundary conditions that are specific to the multiphase models.

   i. (VOF and Eulerian models) If you enabled the **Wall Adhesion** option in the **Phase Interaction** dialog box, you can specify the contact angle at the wall for each pair of phases as a constant (as shown in Figure 24.12: The Wall Dialog Box for a Mixture in a VOF or Eulerian Multiphase Calculation with Wall Adhesion (p. 1394)) or a user-defined function (see the Fluent Customization Manual for more information).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.12: The Wall Dialog Box for a Mixture in a VOF or Eulerian Multiphase Calculation with Wall Adhesion



The contact angle (θ_w in Figure 24.31: Measuring the Contact Angle (p. 1442)) is the angle between the wall and the tangent to the interface at the wall, measured inside the phase listed in the left column under **Wall Adhesion** in the **Momentum** tab of the **Wall** dialog box. For example, if you are setting the contact angle between the oil and air phases in the **Wall** dialog box shown in Figure 24.12: The Wall Dialog Box for a Mixture in a VOF or Eulerian Multiphase Calculation with Wall Adhesion (p. 1394), θ_w is measured inside the oil phase.

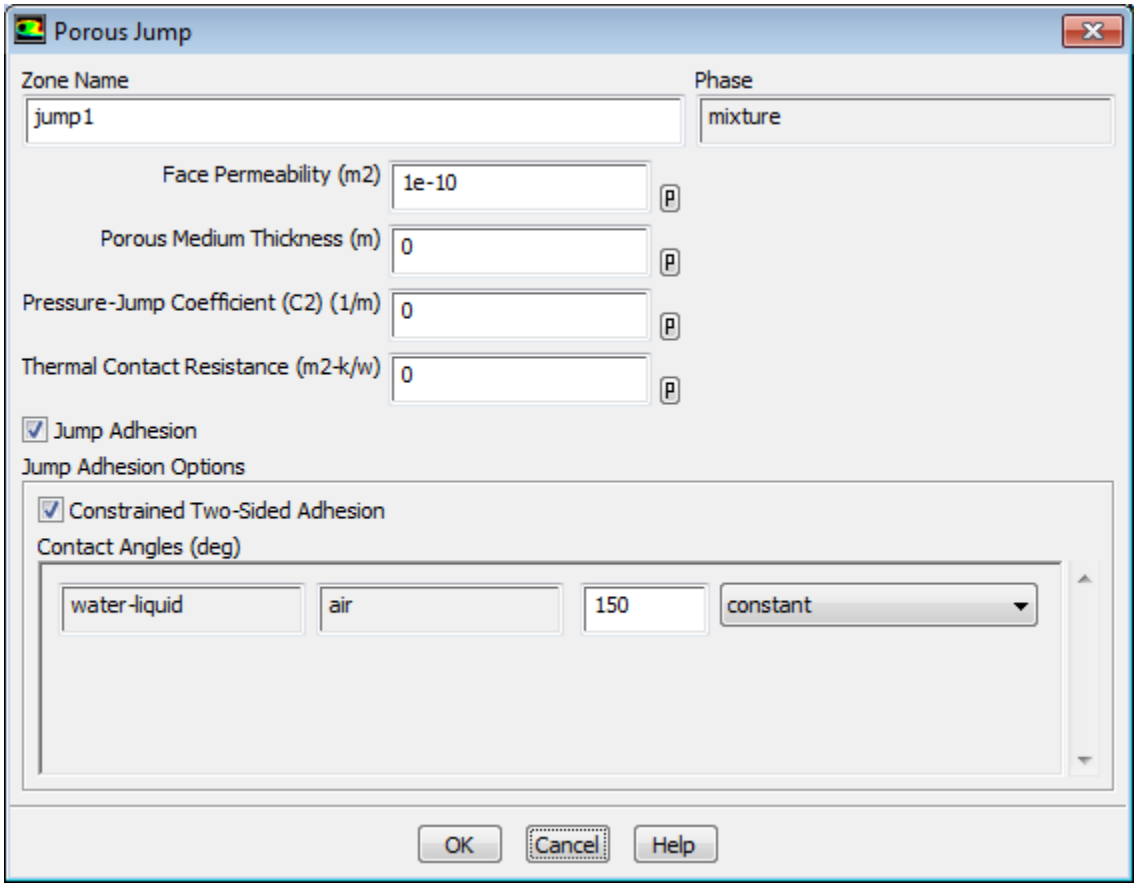
The default value for all pairs is 90 degrees, which is equivalent to no wall adhesion effects (that is, the interface is normal to the adjacent wall). A contact angle of 45°, for example, corresponds to water creeping up the side of a container, as is common with water in a glass.

ii. (VOF model) If you enabled the **Jump Adhesion** option in the **Phase Interaction** dialog box, specify the contact angle at the porous jump for each pair of phases. If you enable the **Jump Adhesion** option in the **Phase Interaction** dialog box, this option becomes visible at each of the porous jump

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

boundaries. You can enable or disable the **Jump Adhesion** option in the **Porous Jump** dialog boxes and provide the inputs for the contact angle at the desired porous jump boundary, as shown in Figure 24.13: The Porous Jump Dialog Box Displaying Jump Adhesion (p. 1395).

Figure 24.13: The Porous Jump Dialog Box Displaying Jump Adhesion



The contact angle θ_w is the angle at the porous jump. To constrain the contact angle at the porous jump based on porous or non-porous fluid zones, enable the **Constrained Two-Sided Adhesion** option. Otherwise, if it is disabled, then the forced two-sided adhesion treatment is in effect. For more detail, see Jump Adhesion.

e. Click **OK** once you complete the boundary condition definition for the mixture.

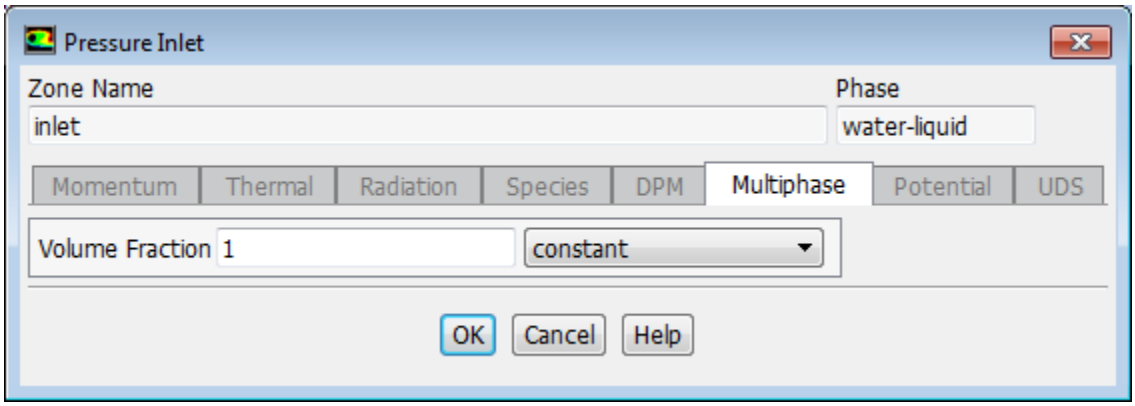
3. Set the conditions for each phase at this boundary, if necessary. (See Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398) for information about which conditions need to be set for the individual phases.)

   a. In the **Phase** drop-down list, select the phase (for example, **water**).

> **Important**
>
> Note that, when you select one of the individual phases (rather than the mixture), only one type of zone appears in the **Type** drop-down list. It is not possible to assign phase-specific zone types at a given boundary; the zone type is specified for the mixture, and it applies to all of the individual phases.

b. Click **Edit...** to open the boundary condition dialog box for this phase (for example, the **Pressure Inlet** dialog box, shown in Figure 24.14: The Pressure Inlet Dialog Box for a Phase (p. 1396)).

Figure 24.14: The Pressure Inlet Dialog Box for a Phase

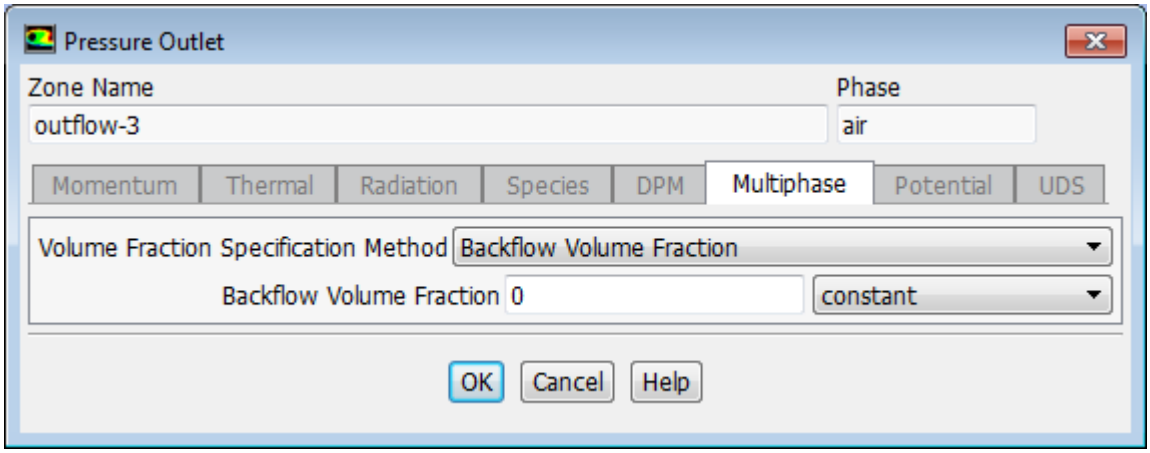


c. Specify the boundary conditions for the phase. Note that only those conditions that apply to the individual phase, as described in Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398), will appear in this dialog box.

d. (Secondary phase only) For the pressure outlet, exhaust fan or outlet vent boundary, you can specify the volume fraction specification method as one of the following options:

- **Backflow Volume Fraction**: You can define the backflow volume fraction as a constant, a profile (see Profiles (p. 435)), or a user-defined function (see the Fluent Customization Manual).

Figure 24.15: The Pressure Outlet Dialog Box for a Phase



- **From Neighboring Cell**: This option does not require the specification of the backflow volume fraction, and the volume fraction value is directly taken from the neighboring cells.

  In the case of reverse flow at the pressure outlet boundary, sometimes it becomes tricky to specify the correct values for the backflow volume fraction. Incorrect specification might lead to instability, convergence issues and unphysical behaviour. The backflow volume fraction specification from the neighboring interior cells can be a good choice if information at the pressure outlet boundary is not known.

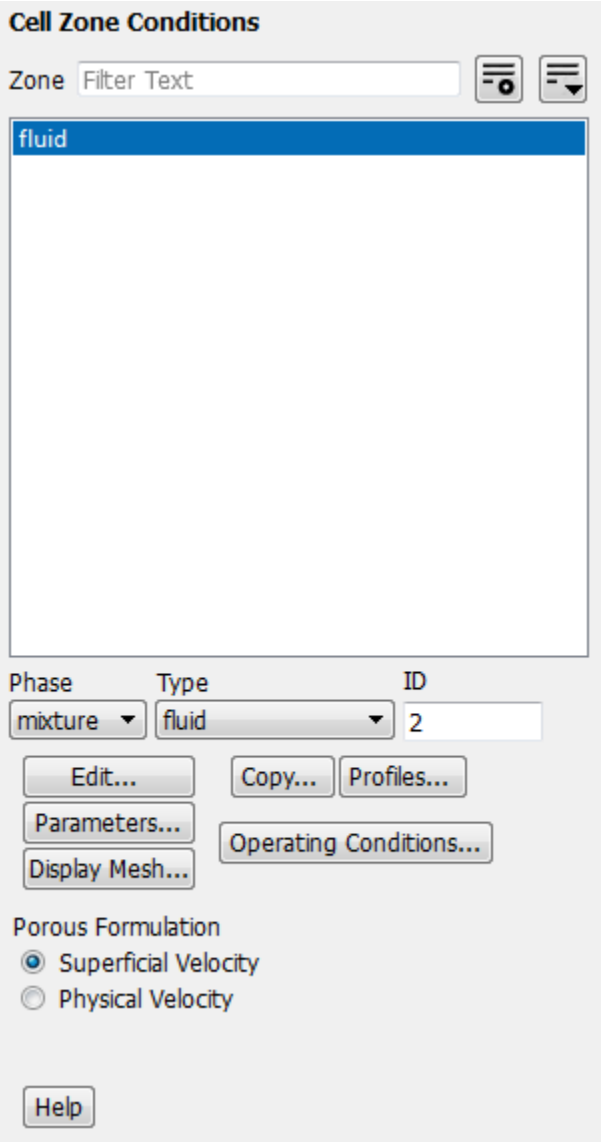
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

e. Click **OK** once you complete the boundary condition definition for the phase.

24.2.11.2. Steps for Setting Cell Zone Conditions

Setup → Cell Zone Conditions

Figure 24.16: The Cell Zone Conditions Task Page



The steps for specifying the mixture and individual phase cell zone conditions are listed below:

1. Select the cell zone in the **Zone** list in the **Cell Zone Conditions** task page.

2. If needed, set the cell zone conditions for the mixture. (For information about which conditions need to be set for the mixture, refer to Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398).)

   a. In the **Phase** drop-down list, select **mixture**.

   b. Make sure that the selected **Type** is appropriate for this zone and click **Edit...**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

c. In the **Fluid** dialog box, set the cell zone conditions that are applicable to the mixture.

d. Define additional cell zone conditions that are specific to the multiphase models.

i. (VOF and Eulerian models) If **Zonal Discretization** is enabled in the **Interface Modeling Options** dialog box, you can specify the **Compressive Scheme Slope Limiter** in the **Multiphase** tab of the **Fluid** dialog box. The setting of the slope limiter can be any value between 0 and 2, inclusive. Values of 0, 1, and 2 correspond to first order upwind, second order upwind, and compressive discretization, respectively with intermediate values resulting in a blended formulation. For more details about the slope limiter, refer to The Compressive Scheme and Interface-Model-based Variants in the *Fluent Theory Guide*.

3. If required, set the conditions for each phase. (See Boundary and Cell Zone Conditions for the Mixture and the Individual Phases (p. 1398) for information about which conditions need to be set for the individual phases.)

a. In the **Phase** drop-down list, select the phase (for example, **water**) and click **Edit...**.

b. In the **Fluid** dialog box, set the cell zone conditions that are applicable to the individual phase.

For more information about inputs for cell zone conditions, see Fluid Conditions (p. 252).

24.2.11.3. Boundary and Cell Zone Conditions for the Mixture and the Individual Phases

The boundary conditions you need to specify for the mixture and for the individual phases will depend on which multiphase model you are using.

Details for each model are provided in the following sections:

24.2.11.3.1. VOF Model
24.2.11.3.2. Mixture Model
24.2.11.3.3. Eulerian Model

24.2.11.3.1. VOF Model

If you are using the VOF model, the conditions you need to specify for each type of boundary zone are listed below and summarized in Table 24.4: Phase-Specific and Mixture Conditions for the VOF Model (p. 1399).

- For an inlet vent, intake fan, pressure inlet, or velocity inlet, there are no conditions to be specified for the primary phase. For each secondary phase, you will need to set the volume fraction as a constant, a profile (see Profiles (p. 435)), or a user-defined function (see the Fluent Customization Manual). All other conditions are specified for the mixture.

- For an exhaust fan, outlet vent, or pressure outlet, there are no conditions to be specified for the primary phase. For each secondary phase, you will need to specify the volume fraction specification method as either **Backflow Volume Fraction** or **From Neighboring Cell** (see step 3. in Steps for Setting Boundary Conditions (p. 1391)). All other conditions are specified for the mixture.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. All other conditions are specified for the mixture.

  Important

  Note that if you read a VOF case that was set up in a version of ANSYS Fluent prior to 6.1, you will need to redefine the conditions at the mass flow inlets.

- For an axis, fan, outflow, periodic, porous jump, radiator, solid, symmetry, or wall zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases.
- For a wall zone, you can specify the contact angle for the mixture if the wall adhesion option is enabled.
- For a fluid zone, mass sources are specified for the individual phases, and all other sources are specified for the mixture.
  - If the fluid zone is not porous, all other conditions are specified for the mixture.
  - If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See User Inputs for Porous Media (p. 267) for the mixture.
  - If **Open Channel Flow** and/or **Open Channel Wave BC** is/are enabled in the **Multiphase Model** dialog box, then the **Numerical Beach** option becomes available under the **Multiphase** tab of the **Fluid** dialog box. To learn how to include numerical beach in your simulation, refer to Numerical Beach Treatment for Open Channels (p. 1432).

See Cell Zone and Boundary Conditions (p. 237) for details about the relevant conditions for each type of boundary. Note that the pressure far-field boundary is not available with the VOF model.

Table 24.4: Phase-Specific and Mixture Conditions for the VOF Model

Type	Primary Phase	Secondary Phase	Mixture
inlet vent, intake fan, pressure inlet, velocity inlet	nothing	volume fraction	all others
exhaust fan, outlet vent, pressure outlet	nothing	volume fraction specification method	all others
mass flow inlet	mass flow/flux	mass flow/flux	all others
axis; fan; outflow; periodic; porous jump; radiator; solid; symmetry; wall	nothing	nothing	all others
pressure far-field	not available	not available	not available
fluid	mass source; other porous inputs	mass source; other porous inputs	porous zone; porosity; all others

24.2.11.3.2. Mixture Model

If you are using the mixture model, the conditions you need to specify for each type of boundary zone are listed below and summarized in Table 24.5: Phase-Specific and Mixture Conditions for the Mixture Model (p. 1400).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For an exhaust fan, outlet vent, or pressure outlet, there are no conditions to be specified for the primary phase. For each secondary phase, you will need to specify the volume fraction specification method as either **Backflow Volume Fraction** or **From Neighboring Cell** (step 3 in Steps for Setting Boundary Conditions (p. 1391). All other conditions are specified for the mixture.

- For an inlet vent, intake fan, or pressure inlet, you will specify for the mixture which direction specification method will be used at this boundary (**Normal to Boundary** or **Direction Vector**). If you select the **Direction Vector** specification method, you will specify the coordinate system (3D only) and flow-direction components for the individual phases. For each secondary phase, you will need to set the volume fraction (as described above). All other conditions are specified for the mixture.

- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. All other conditions are specified for the mixture.

  Important

  Note that if you read a mixture multiphase case that was set up in a version of ANSYS Fluent previous to 6.1, you will need to redefine the conditions at the mass flow inlets.

- For a velocity inlet, you will specify the velocity for the individual phases. For each secondary phase, you will need to set the volume fraction (as described above). All other conditions are specified for the mixture.

- For an axis, fan, outflow, periodic, porous jump, radiator, solid, symmetry, or wall zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases. Outflow boundary conditions are not available for the cavitation model.

- For a fluid zone, mass sources are specified for the individual phases, and all other sources are specified for the mixture.

  If the fluid zone is not porous, all other conditions are specified for the mixture.

  If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See User Inputs for Porous Media (p. 267) for details about these inputs. All other conditions are specified for the mixture.

See Cell Zone and Boundary Conditions (p. 237) for details about the relevant conditions for each type of boundary. Note that the pressure far-field boundary is not available with the mixture model.

Table 24.5: Phase-Specific and Mixture Conditions for the Mixture Model

Type	Primary Phase	Secondary Phase	Mixture
exhaust fan; outlet vent; pressure outlet	nothing	volume fraction specification method	all others
inlet vent; intake fan; pressure inlet	coord. system; flow direction	coord. system; flow direction; volume fraction	dir. spec. method; all others
mass flow inlet	mass flow/flux	mass flow/flux	all others
velocity inlet	velocity	velocity; volume fraction	all others
axis; fan; outflow (n/a for cavitation model); periodic;	nothing	nothing	all others

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Type	Primary Phase	Secondary Phase	Mixture
porous jump; radiator; solid; symmetry; wall			
pressure far-field	not available	not available	not available
fluid	mass source; other porous inputs	mass source; other porous inputs	porous zone; porosity; all others

24.2.11.3.3. Eulerian Model

If you are using the Eulerian model, the conditions you need to specify for each type of boundary zone are listed below and summarized in

- Table 24.6: Phase-Specific and Mixture Conditions for the Eulerian Model (for Laminar Flow) (p. 1404)
- Table 24.7: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Mixture Turbulence Model) (p. 1404)
- Table 24.8: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Dispersed Turbulence Model) (p. 1405)
- Table 24.9: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Per-Phase Turbulence Model) (p. 1405)

Note that the specification of turbulence parameters will depend on which of the three multiphase turbulence models you are using, as indicated in

- Table 24.7: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Mixture Turbulence Model) (p. 1404)
- Table 24.8: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Dispersed Turbulence Model) (p. 1405)
- Table 24.9: Phase-Specific and Mixture Conditions for the Eulerian Model (with the Per-Phase Turbulence Model) (p. 1405)

See Turbulence Models in the Theory Guide and Modeling Turbulence (p. 1474) for more information about multiphase turbulence models.

- For an exhaust fan, outlet vent, or pressure outlet, there are no conditions to be specified for the primary phase if you are modeling laminar flow or using the mixture turbulence model (the default multiphase turbulence model), except for backflow total temperature if heat transfer is on.

  For each secondary phase, you will need to specify the volume fraction specification method as either **Backflow Volume Fraction** or **From Neighboring Cell** (step 3 in Steps for Setting Boundary Conditions (p. 1391). If the phase is granular, you will also need to set its backflow granular temperature. If heat transfer is on, you will also need to set the backflow total temperature.

  If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

  All other conditions are specified for the mixture.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For an inlet vent, intake fan, or pressure inlet, you will specify for the mixture which direction specification method will be used at this boundary (**Normal to Boundary** or **Direction Vector**). If you select the **Direction Vector** specification method, you will specify the coordinate system (3D only) and flow-direction components for the individual phases. If heat transfer is on, you will also need to set the total temperature for the individual phases.

  For each secondary phase, you will need to set the volume fraction (as described above). If the phase is granular, you will also need to set its granular temperature.

  If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

  All other conditions are specified for the mixture.

- For a mass flow inlet, you will need to set the mass flow rate, mass flux, or average mass flux for each individual phase. You will also need to specify the temperature of each phase, since the energy equations are solved for each phase.

  For mass flow inlet boundary conditions, you can specify the slip velocity between phases. When you select a mass flow inlet boundary for the secondary phase, two options will be available for the **Slip Velocity Specification Method**, as shown in Figure 24.17: Mass-Flow Inlet Boundary Condition Dialog Box (p. 1403) :

  – **Velocity Ratio**

    The value for the **Velocity Ratio** is the secondary phase to primary phase velocity ratio. By default, it is 1.0, which means velocities are the same (no slip). By entering a ratio that is greater than 1.0, you are indicating a larger secondary phase velocity. Otherwise, you can enter a ratio that is less than 1.0 to indicate a smaller secondary phase velocity.

  – **Volume Fraction**

    If you specify the volume fraction at an inlet, ANSYS Fluent will calculate the phase velocities.

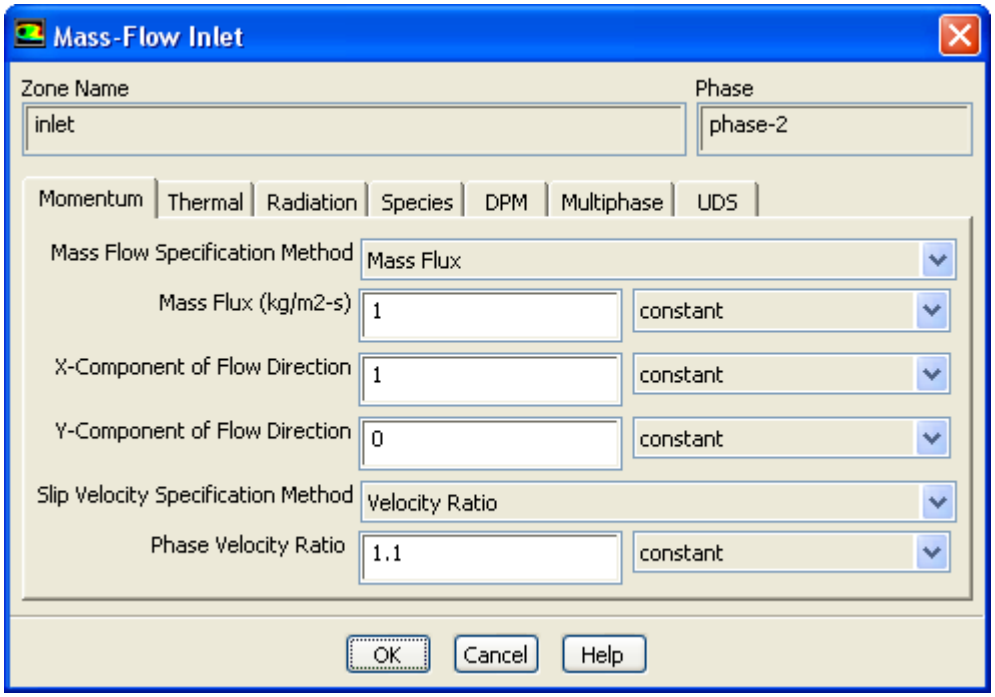
Important

– If a secondary phase has zero mass flux (that is, the Eulerian model is used to run a single phase case), neither **Velocity Ratio** nor **Volume Fraction** will affect the solution.

– The **Velocity Ratio** and **Volume Fraction** slip velocity methods cannot be mixed for different secondary phases. That is, you should specify one or the other condition for all phases.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.17: Mass-Flow Inlet Boundary Condition Dialog Box



- For a velocity inlet, you will specify the velocity for the individual phases. If heat transfer is on, you will also need to set the static temperature for the individual phases.

  For each secondary phase, you will need to set the volume fraction (as described above). If the phase is granular, you will also need to set its granular temperature.

  If you are using the mixture turbulence model, you will need to specify the turbulence boundary conditions for the mixture. If you are using the dispersed turbulence model, you will need to specify them for the primary phase. If you are using the per-phase turbulence model, you will need to specify them for the primary phase and for each secondary phase.

  All other conditions are specified for the mixture.

- For an axis, outflow, degassing, periodic, solid, or symmetry zone, all conditions are specified for the mixture. There are no conditions to be set for the individual phases.

- For a wall zone, shear conditions are specified for the individual phases. All other conditions are specified for the mixture, including thermal boundary conditions, if heat transfer is on.

- For a fluid zone, all source terms and fixed values are specified for the individual phases, unless you are using the mixture turbulence model or the dispersed turbulence model. If you are using the mixture turbulence model, source terms and fixed values for turbulence are specified instead for the mixture. If you are using the dispersed turbulence model, they are specified only for the primary phase.

  – If the fluid zone is not porous, all other conditions are specified for the mixture.

  – If the fluid zone is porous, you will enable the **Porous Zone** option in the **Fluid** dialog box for the mixture. The porosity inputs (if relevant) are also specified for the mixture. The resistance coefficients and direction vectors, however, are specified separately for each phase. See User Inputs for Porous Media (p. 267) for details about these inputs. All other conditions are specified for the mixture.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

See Cell Zone and Boundary Conditions (p. 237) for details about the relevant conditions for each type of boundary. Note that the pressure far-field, fan, porous jump, radiator, and mass flow inlet boundaries are not available with the Eulerian model.

24.2.11.4. Steps for Copying Cell Zone and Boundary Conditions

The steps for copying cell zone and boundary conditions for a multiphase flow are slightly different from those described in Copying Cell Zone and Boundary Conditions (p. 242) for a single-phase flow. The modified steps are listed below:

1. In the **Cell Zone Conditions** or **Boundary Conditions** task page, click the **Copy...** button. This will open the **Copy Conditions** dialog box.

2. In the **From Cell Zone** or **From Boundary Zone** list, select the zone that has the conditions you want to copy.

3. In the **To Cell Zones** or **To Boundary Zones** list, select the zone or zones to which you want to copy the conditions.

4. In the **Phase** drop-down list, select the phase for which you want to copy the conditions (either **mixture** or one of the individual phases).

   Important

   Note that copying the boundary conditions for one phase does not automatically result in the boundary conditions for the other phases and the mixture being copied as well. You need to copy the conditions for each phase on each boundary of interest.

5. Click **Copy**. ANSYS Fluent will set *all* of the selected phase's (or mixture's) boundary conditions on the zones selected in the **To Cell Zones** or **To Boundary Zones** list to be the same as that phase's conditions on the zone selected in the **From Cell Zone** or **From Boundary Zone** list. (You cannot copy a subset of the conditions, such as only the thermal conditions.)

See Copying Cell Zone and Boundary Conditions (p. 242) for additional information about copying boundary conditions, including limitations.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.2.12. Setting Initial Volume Fractions

Once you have initialized the flow (as described in Initializing the Solution (p. 1591)), you can define the initial distribution of the phases. For a transient simulation, this distribution will serve as the initial condition at $t=0$; for a steady-state simulation, setting an initial distribution can provide added stability in the early stages of the calculation.

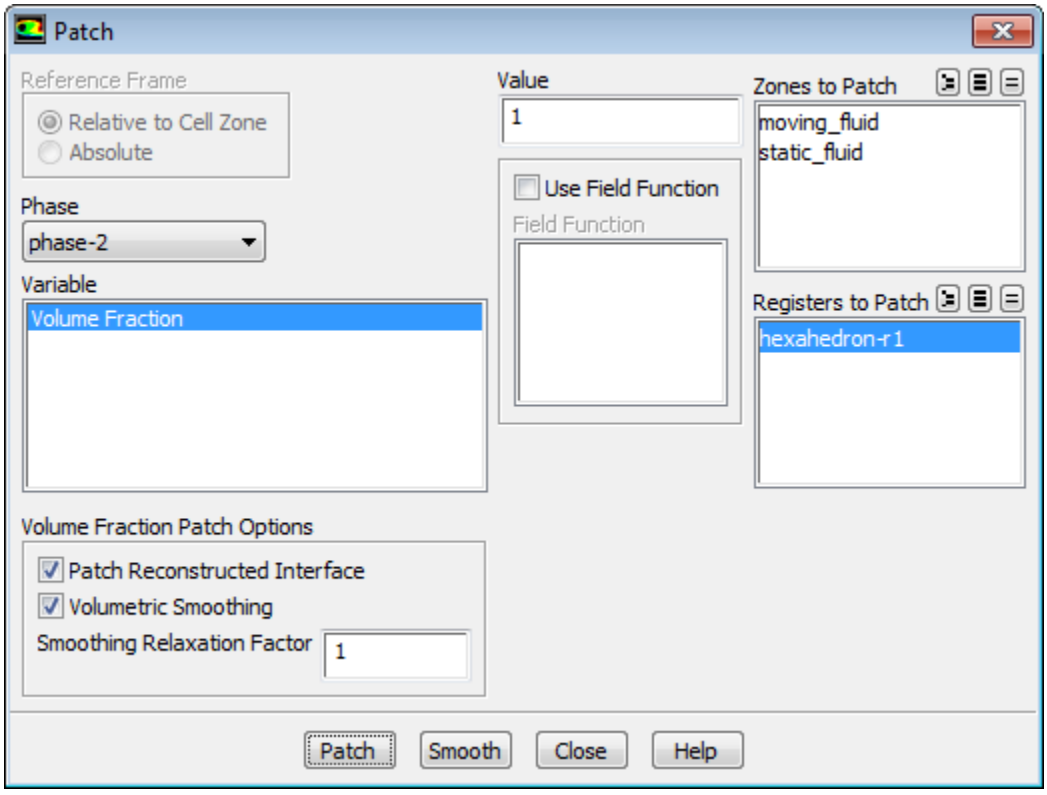
You can patch an initial volume fraction for each secondary phase using the Patch Dialog Box (p. 2522).

Solution → Initialization → Patch...

If the region in which you want to patch the volume fraction is defined as a separate cell zone, you can simply patch the value there. Otherwise, you can create a cell "register" that contains the appropriate cells and patch the value in the register. See Patching Values in Selected Cells (p. 1593) for details.

24.2.12.1. Options for Patching Volume Fraction in the VOF Model

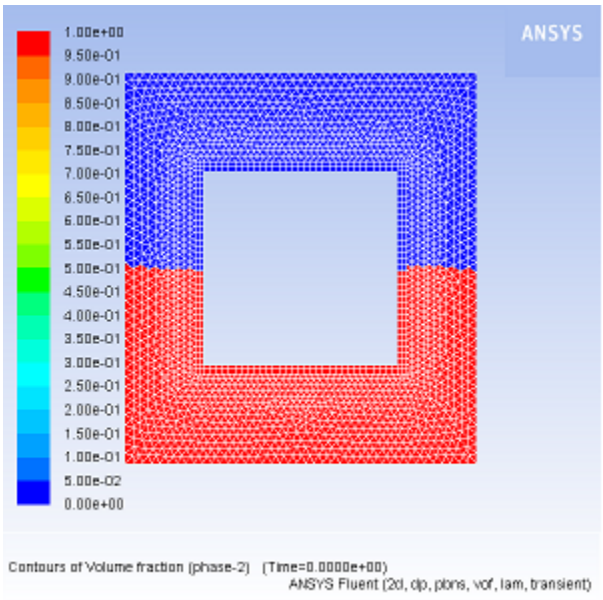
If you are using the VOF model or the Eulerian model with Multi-Fluid VOF enabled, you have additional options for how the volume fraction is patched in a user-defined register. By default the patching procedure will initialize all of the cells in the register with the specified volume fraction, without any special treatment for cells that are intersected by the fluid-fluid interface.



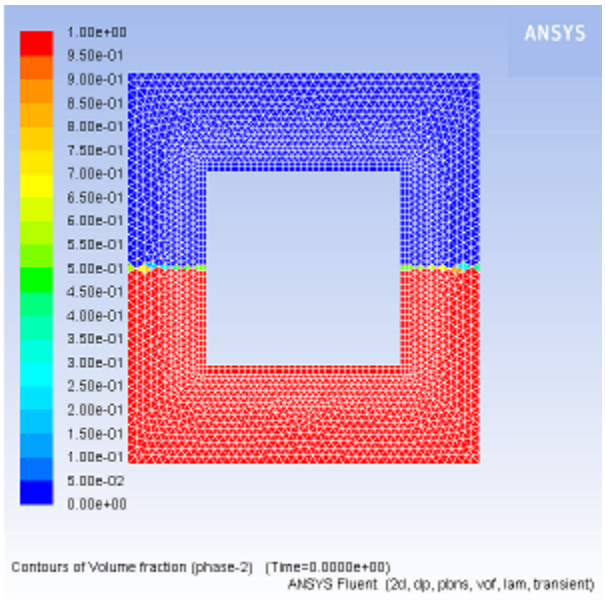
Patch Reconstructed Interface

This option uses piecewise-linear interface reconstruction to identify the fluid-fluid interface and patches the actual volume fraction field in the cells that intersect the interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Without Patch Reconstructed Interface



With Patch Reconstructed Interface

Important

The **Patch Reconstructed Interface** algorithm requires that the register coordinates in the **Region Adaption** dialog box be well-ordered. That is: **X Min** < **X Max**; **Y Min** < **Y Max**; **Z Min** < **Z Max**. In particular, if you use the **Select Points with Mouse** feature to specify the coordinates, be sure that this condition is met.

The **Patch Reconstructed Interface** will be applied only on the last register that was defined, even if multiple registers are selected in the **Patch** dialog box. Therefore, it is recommended that you create and patch registers one at a time.

Volumetric Smoothing

This option smooths the volume fraction field on-demand by taking the volumetric average over the cell neighbors. This can help provide better solution stability at startup. After enabling **Volumetric Smoothing**, you can click **Smooth** to apply the smoothing. Note that the smoothing is applied to the volume fraction field for all phases in the full domain. The **Smoothing Relaxation Factor** controls the degree of smoothing applied. You can specify a value between 0 (no smoothing) and 1 (maximum smoothing). For most cases, the default value is recommended. For fine meshes you may choose to try a larger value to aid solution startup. However, excessively large values can have an undesirable effect during the solution as interface sharpening discretization schemes may deteriorate the initial field.

The **Smooth** command can be used at any time after the solution has been initialized. It can therefore also be used after reading a data file for postprocessing. However, note that the smoothed field will overwrite the original volume fraction field in this case. Also note that you must select a secondary phase variable from the drop-down list in the Patch dialog box to expose the **Volumetric Smoothing** option.

24.3. Setting Up the VOF Model

For background information about the VOF model and the limitations that apply, refer to Overview of the VOF Model in the Theory Guide.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This section is organized as follows:

24.3.1. Solving Steady-State VOF Problems
24.3.2. Guidelines for Using the Multiphase Pseudo Transient Solver
24.3.3. Including Coupled Level Set with the VOF Model
24.3.4. Modeling Open Channel Flows
24.3.5. Modeling Open Channel Wave Boundary Conditions
24.3.6. Recommendations for Open Channel Initialization
24.3.7. Numerical Beach Treatment for Open Channels
24.3.8. Defining the Phases for the VOF Model
24.3.9. Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation
24.3.10. Modeling Solidification/Melting

24.3.1. Solving Steady-State VOF Problems

For steady-state VOF problems, ANSYS Fluent automatically enables the **Pseudo Transient** solution method along with the **Coupled** pressure-velocity coupling scheme for better stability and faster convergence. For more information about pseudo transient solutions, see Performing Pseudo Transient Calculations (p. 1601).

24.3.2. Guidelines for Using the Multiphase Pseudo Transient Solver

When using the **Pseudo Transient** solution method in multiphase applications, follow the guidelines provided below:

- For the fixed (**User Defined**) time step method, you must provide a suitable pseudo time-step size to the solver. You can use the **Automatic** time step method to estimate the pseudo time step size for the simulation. This can be done by setting the **Verbosity** to 1 and simulating your case for a few iterations. The pseudo-time step size will be printed in the Fluent console.
- For the **Automatic** time step method, decreasing the **Time Scale Factor** to a lower value (about 0.3) will provide better solution stability.
- Sometimes, for stiff flow problems, convergence may not be achieved when using the **Automatic** time step method. In such cases, consider switching to the fixed (**User Defined**) time step method instead.
- For steady state problems, you should never evaluate convergence based on residuals alone. To better judge convergence, you should also monitor appropriate field variables at a particular location until the value stops changing.
- The **Coupled with Volume Fractions** option is recommended for open channel flow applications.

24.3.3. Including Coupled Level Set with the VOF Model

When using the VOF formulation, you can couple the level set method with it to help overcome some limitations that exist in the interface tracking method of the VOF model and the level set method. To use the coupled level set method with VOF, perform the following:

1. Open the **Multiphase Model** dialog box.

   Setup → **Models** → **Multiphase** → **Edit...**

2. Under **Model**, enable **Volume of Fluid**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Under **Coupled Level Set + VOF**, enable **Level Set** (see Figure 24.1: Multiphase Model Dialog Box for the VOF Model (p. 1368)).

4. (optional) In some cases, spurious currents can arise from the application of the surface tension force in the momentum equation. In these cases you can use the `/define/models/multiphase/coupled-level-set` text command to use a revised formulation of the surface tension force that weights the force towards the heavier phase in the interface cells. You can choose from `none` (the default), `density-correction`, and `heaviside-correction`.

After the **Level Set** option is enabled, proceed as you normally would when setting up the VOF model (described in Setting Up the VOF Model (p. 1408)). For theoretical information, refer to Coupled Level-Set and VOF Model.

Note

When using the **Level Set** option, the recommended scheme is the geo-reconstruct scheme (see The Geometric Reconstruction Scheme).

Important

- The level set method is only suitable for two-phase flow regime, where two fluids are not interpenetrating.
- The level set model can only be used when the VOF model is turned on. No mass transfer is allowed.
- The level set method is not compatible with the dynamic mesh model.

Normally, zero flux of the level set function is set as the default for the boundary conditions. Due to the geometrical re-initialization procedure at each time step, the boundary conditions shall not have any significant effect on the results. For more information, see Re-initialization of the Level-set Function via the Geometrical Method.

24.3.4. Modeling Open Channel Flows

Using the VOF formulation, open channel flows can be modeled in ANSYS Fluent. To start using the open channel flow boundary condition, perform the following:

1. Enable **Gravity** and set the gravitational acceleration fields.

   Setup → **General** **Gravity** → **On**

2. Enable the volume of fluid model.

   a. Open the **Multiphase Model** dialog box.

      Setup → **Models** → **Multiphase** → **Edit...**

   b. Under **Model**, enable **Volume of Fluid**.

   c. Under **Formulation**, select either **Implicit** or **Explicit**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. Under **VOF Sub-Models**, select **Open Channel Flow**.

> **Note**
>
> The default VOF formulation is set to **Implicit** after enabling the **Open Channel Flow** option. This is done to allow the use of larger time step sizes for such applications.

In order to set specific parameters for a particular boundary for open channel flows, enable the **Open Channel** option in the **Multiphase** tab of the corresponding boundary condition dialog box. Table 24.10: Open Channel Boundary Parameters for the VOF Model (p. 1411) summarizes the types of boundaries available to the open channel flow boundary condition, and the additional parameters needed to model open channel flow. For more information on setting boundary condition parameters, see Cell Zone and Boundary Conditions (p. 237).

Table 24.10: Open Channel Boundary Parameters for the VOF Model

Boundary Type	Parameter
pressure inlet	Inlet Group ID; Secondary Phase for Inlet; Flow Specification Method; Free Surface Level, Bottom Level; Velocity Magnitude
pressure outlet	Outlet Group ID; Pressure Specification Method; Free Surface Level; Bottom Level
mass flow inlet	Inlet Group ID; Secondary Phase for Inlet; Free Surface Level; Bottom Level; Mass Flow Rates for the Phases
velocity inlet	Secondary Phase for Inlet; Free Surface Level, Averaged Velocity Inputs/Segregated Velocity Inputs (Available with Open Channel Wave Boundary Condition)
outflow	Flow Rate Weighting

24.3.4.1. Defining Inlet Groups

Open channel systems involve the flowing fluid (the secondary phase) and the fluid above it (the primary phase).

If both phases enter through the separate inlets (for example, `inlet-phase2` and `inlet-phase1`), these two inlets form an inlet group. This inlet group is recognized by the parameter **Inlet Group ID**, which will be same for both the inlets that make up the inlet group. On the other hand, if both the phases enter through the same inlet (for example, `inlet-combined`), then the inlet itself represents the inlet group.

> **Important**
>
> In three-phase flows, only one secondary phase is allowed to pass through one inlet group.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.3.4.2. Defining Outlet Groups

Outlet-groups can be defined in the same manner as the inlet groups.

Important

In three-phase flows, the outlet should represent the outlet group, that is, separate outlets for each phase are not recommended in three-phase flows.

24.3.4.3. Setting the Inlet Group

For pressure inlets and mass flow inlets, the **Inlet Group ID** is used to identify the different inlets that are part of the same inlet group. For instance, when both phases enter through the same inlet (single face zone), then those phases are part of one inlet group and you would set the **Inlet Group ID** to 1 for that inlet (or inlet group).

In the case where the same inlet group has separate inlets (different face zones) for each phase, then the **Inlet Group ID** will be the same for each inlet of that group.

When specifying the inlet group, use the following guidelines:

- Since the **Inlet Group ID** is used to identify the inlets of the same inlet group, general information such as **Free Surface Level**, **Bottom Level**, or the mass flow rate for each phase should be the same for each inlet of the same inlet group.
- You should specify a different **Inlet Group ID** for each distinct inlet group.

  For example, consider the case of two inlet groups for a particular problem. The first inlet group consists of water and air entering through the same inlet (a single face zone). In this case, you would specify an inlet group ID of 1 for that inlet (or inlet group). The second inlet group consists of oil and air entering through the same inlet group, but each uses a different inlet (`oil-inlet` and `air-inlet`) for each phase. In this case, you would specify the same **Inlet Group ID** of 2 for both of the inlets that belong to the inlet group.

24.3.4.4. Setting the Outlet Group

For pressure outlet boundaries, the **Outlet Group ID** is used to identify the different outlets that are part of the same outlet group. For instance, when both phases enter through the same outlet (single face zone), then those phases are part of one outlet group and you would set the **Outlet Group ID** to 1 for that outlet (or outlet group).

In the case where the same outlet group has separate outlets (different face zones) for each phase, then the **Outlet Group ID** will be the same for each outlet of that group.

When specifying the outlet group, use the following guidelines:

- Since the **Outlet Group ID** is used to identify the outlets of the same outlet group, general information such as **Free Surface Level** or **Bottom Level** should be the same for each outlet of the same outlet group.
- You should specify a different **Outlet Group ID** for each distinct outlet group.

  For example, consider the case of two outlet groups for a particular problem. The first outlet group consists of water and air exiting from the same outlet (a single face zone). In this case, you would

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

specify an outlet number of 1 for that outlet (or outlet group). The second outlet group consists of oil and air exiting through the same outlet group, but each uses a different outlet (`oil-outlet` and `air-outlet`) for each phase. In this case, you would specify the same **Outlet Group ID** of 2 for both of the outlets that belong to the outlet group.

Important

For three-phase flows, when all the phases are leaving through the same outlet, the outlet should consist only of a single face zone.

24.3.4.5. Determining the Free Surface Level

For the appropriate boundary, you need to specify the **Free Surface Level** value. This parameter is available for all relevant boundaries, including pressure outlet, mass flow inlet, and pressure inlet. The **Free Surface Level**, is represented by y_{local} in Equation 17.41 in the Theory Guide.

$$y_{local} = -\left(\vec{a} \cdot \hat{g}\right) \tag{24.2}$$

where $\vec{a}$ is the position vector of any point on the free surface, and $\hat{g}$ is the unit vector in the direction of the force of gravity. Here a horizontal free surface that is normal to the direction of gravity is assumed.

We can simply calculate the free surface level in two steps:

1. Determine the absolute value of height from the free surface to the origin in the direction of gravity.

2. Apply the correct sign based on whether the free surface level is above or below the origin.

If the liquid's free surface level lies above the origin, then the **Free Surface Level** is positive (see Figure 24.18: Determining the Free Surface Level and the Bottom Level (p. 1414)). Likewise, if the liquid's free surface level lies below the origin, then the **Free Surface Level** is negative.

You can also specify a transient profiles for a **Free Surface Level** for the relevant open channel boundaries as shown in the example below:

```
/*********************************************************************
Example UDF that demonstrates transient profile for free surface level
*********************************************************************/

#include "udf.h"

#define H 1.5   /* Original Free surface level */
#define T0 0.2  /* Time */

DEFINE_TRANSIENT_PROFILE(fs_level, current_time)
{
    real level;
    if (current_time <= T0)
      level = H - current_time;
    else
      level = H - T0;

    return level;
}
```

24.3.4.6. Determining the Bottom Level

For the appropriate boundary, you need to specify the **Bottom Level** value. This parameter is available for all relevant boundaries, including pressure outlet, mass flow inlet, and pressure inlet. The **Bottom Level**, is represented by a relation similar to Equation 17.41 in the Theory Guide.

$$y_{bottom} = -\left(\vec{b} \cdot \hat{g}\right) \tag{24.3}$$

where $\vec{b}$ is the position vector of any point on the bottom of the channel, and $\hat{g}$ is the unit vector of gravity. Here we assume a horizontal free surface that is normal to the direction of gravity.

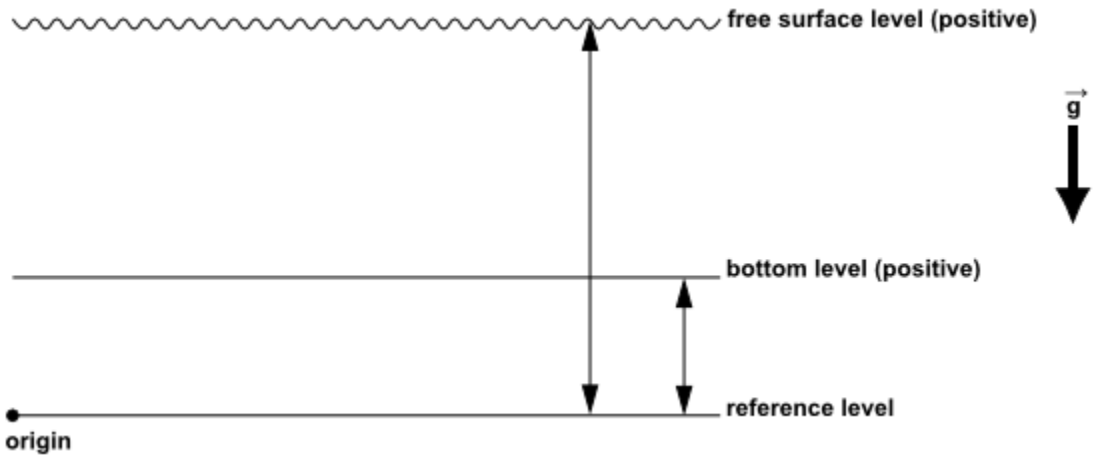
We can simply calculate the bottom level in two steps:

1. Determine the absolute value of depth from the bottom level to the origin in the direction of gravity.

2. Apply the correct sign based on whether the bottom level is above or below the origin.

If the channel's bottom lies above the origin, then the **Bottom Level** is positive (see Figure 24.18: Determining the Free Surface Level and the Bottom Level (p. 1414)). Likewise, if the channel's bottom lies below the origin, then the **Bottom Level** is negative.

Figure 24.18: Determining the Free Surface Level and the Bottom Level



You can also specify a transient profiles for a **Bottom Level** for the relevant open channel boundaries.

24.3.4.7. Specifying the Total Height

The total height, along with the velocity, is used as an option for describing the flow. The total height is given as

$$y_{tot} = y_{local} + \frac{V^2}{2g} \tag{24.4}$$

where V is the velocity magnitude and g is the gravity magnitude.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.3.4.8. Determining the Velocity Magnitude

For pressure inlet boundaries, input for **Velocity Magnitude** is required to calculate the dynamic pressure being used in the total pressure calculation.

Note

The provided **Velocity Magnitude** is not applied to the boundary.

24.3.4.9. Determining the Secondary Phase for the Inlet

For pressure inlets and mass flow inlets, the **Secondary Phase for Inlet** field allows you to choose the desired secondary phase in the case of three-phase flows.

Important

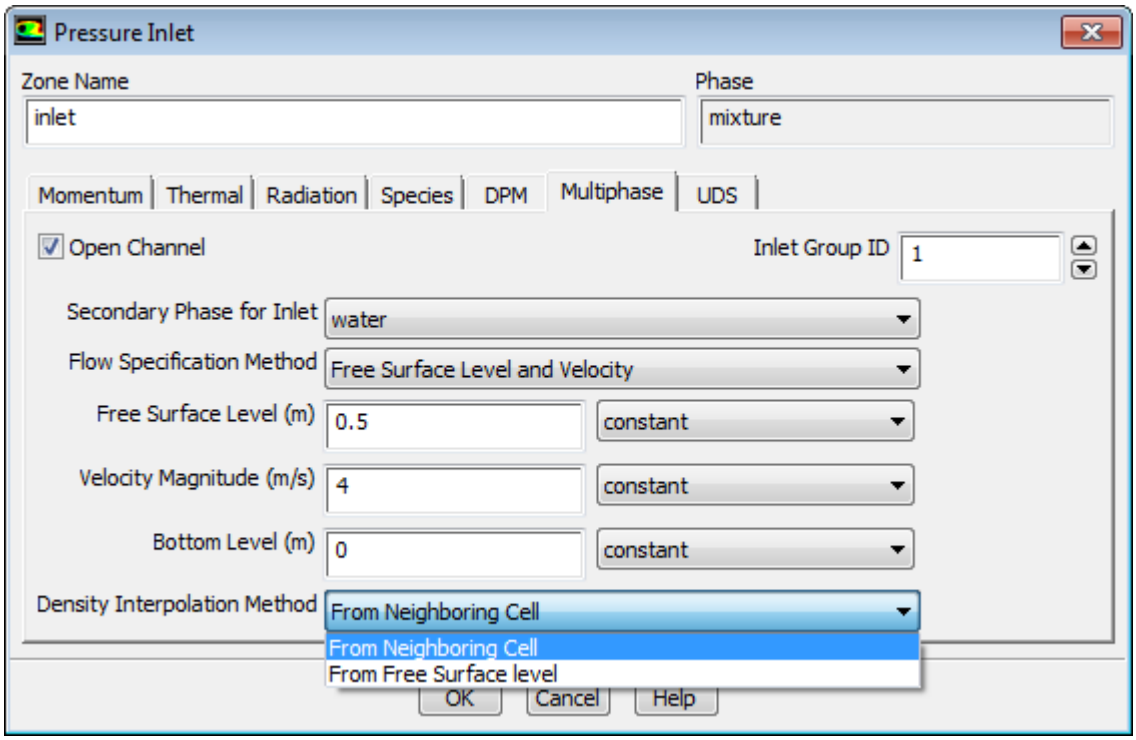
Note that only one secondary phase is allowed to pass through one inlet group.

Consider a problem involving a three-phase flow consisting of air as the primary phase, and oil and water as the secondary phases. Consider also that there are two inlet groups:

- water and air
- oil and air

For the former inlet group, you would choose water as the secondary phase. For the latter inlet group, you would choose oil as the secondary phase (as shown in Figure 24.19: Pressure Inlet for Open Channel Flow (p. 1415)).

Figure 24.19: Pressure Inlet for Open Channel Flow



24.3.4.10. Choosing the Pressure Specification Method

For a pressure outlet boundary, the outlet pressure can be specified in one of three ways:

- by prescribing the free surface level, such as a hydrostatic pressure profile (available for two-phase flow only)
- by specifying the constant pressure
- by specifying the neighboring cell pressure

Note

You can also specify a hydrostatic pressure profile at the pressure outlet for axisymmetric open channel flow. However, there are certain limitations as noted in Limitations (p. 1417).

Important

This option is not available in the case of three-phase flows since the pressure on the boundary is taken from the neighboring cell.

24.3.4.11. Choosing the Density Interpolation Method

For problems involving sub-critical flow, the following options exist for the **Density Interpolation Method**:

- **From Neighboring Cell** is the default option, where the mixture density used in the hydrostatic profile is interpolated using the volume fraction calculated from the neighboring cell.

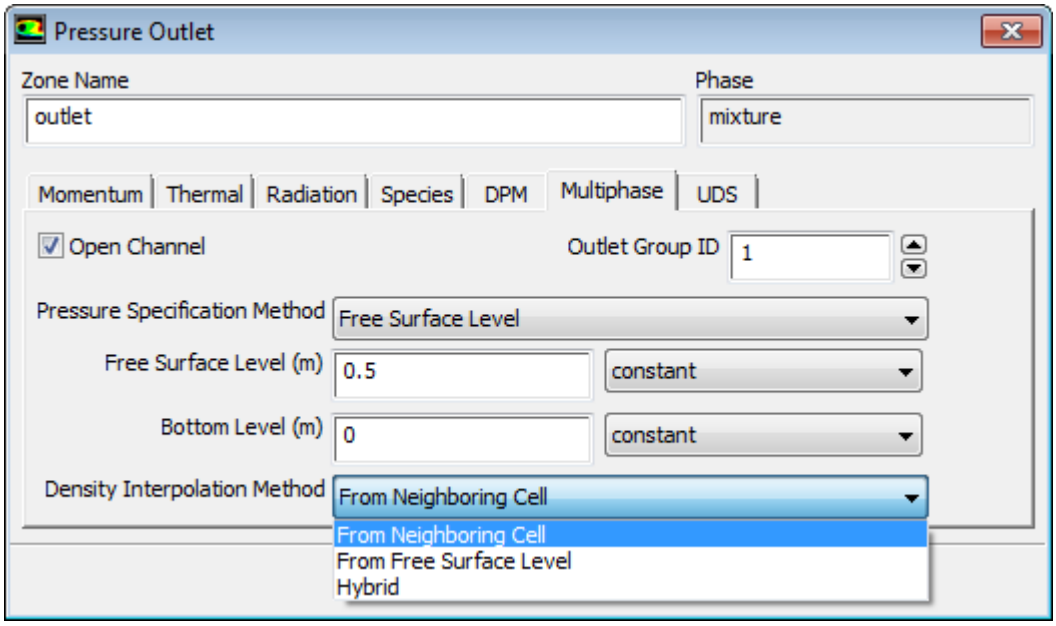
  Note

  In some cases, this method may cause free surface oscillation near the upstream boundaries. These oscillations are particularly visible in cases where boundaries are close to the object; or if the boundary has unstructured mesh near the free surface level. For such cases, it is recommended that you use the `From Free Surface Level` option under **Density Interpolation Method**.

- **From Free Surface Level** where the mixture density used in the hydrostatic profile is interpolated from the volume fraction calculated from the free surface level.
- **Hybrid** where the mixture density used in the hydrostatic profile is calculated either from the **From Neighboring Cell** or **From Free Surface Level** options, depending on the direction of flux. This method is only available at a pressure outlet.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.20: Density Interpolation Method for Open Channel Flow



24.3.4.12. Open Channel Flow Compatibility with Velocity Inlet

For additional information, see the following sections:
24.3.4.12.1. Velocity Inlet, Open Channel Flow, Steady-State
24.3.4.12.2. Velocity Inlet, Open Channel Flow, Transient

Open channel flow compatibility with velocity inlet is provided in the framework of the open channel wave boundary condition, therefore, the **Open Channel Wave BC** option in the Figure 24.1: Multiphase Model Dialog Box for the VOF Model (p. 1368) must be enabled first.

Velocity inlet compatibility allows you to use either averaged or segregated velocity inputs to moving obstacles, water and air, which is not possible using either the pressure inlet or mass flow inlet boundary conditions.

Select the **Open Channel Wave BC** option in the **Velocity Inlet** dialog box. For detailed information about the velocity inputs, see Inputs at Velocity Inlet Boundaries (p. 317).

24.3.4.12.1. Velocity Inlet, Open Channel Flow, Steady-State

you must specify (in the **Multiphase** tab of the **Velocity Inlet** dialog box):

- Secondary phase for the inlet
- Free surface level

24.3.4.12.2. Velocity Inlet, Open Channel Flow, Transient

You must set the **Wave BC Option** to **None** (in the **Multiphase** tab of the **Velocity Inlet** dialog box).

24.3.4.13. Limitations

The following list summarizes some issues and limitations associated with the open channel boundary condition.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- The conservation of the Bernoulli integral does not provide the conservation of mass flow rate for the pressure boundary. In the case of a coarser mesh, there can be a significant difference in mass flow rate from the actual mass flow rate. For finer meshes, the mass flow rate comes closer to the actual value. So, for problems having constant mass flow rate, the mass flow rate boundary condition is a better option. The pressure boundary should be selected when steady and non-oscillating drag is the main objective.
- Specifying the top boundary as the pressure outlet can sometimes lead to a divergent solution. This may be due to the corner singularity at the pressure boundary in the air region or due to the inability to specify local flow direction correctly if the air enters through the top locally.
- Only the heavier phase should be selected as the secondary phase.
- In the case of three-phase flows, only one secondary phase is allowed to enter through one inlet group (that is, the mixed inflow of different secondary phases is not allowed).
- For axisymmetric flow, pressure and mass flow inlets do not support open channel boundary conditions.
- Open channel wave boundary conditions for velocity inlets do not support cases with axisymmetric flow.
- Axisymmetric open channel flow is available for two phase flow and the pressure outlet boundary.
- For axisymmetric open channel flow, the direction of gravity must be aligned with the direction of the axis.

24.3.4.14. Recommendations for Setting Up an Open Channel Flow Problem

The following list represents a list of recommendations for solving problems using the open channel flow boundary condition:

- In the cases where the inlet group has a different inlet for each phase of fluid, then the parameter values (such as **Free Surface Level**, **Bottom Level**, and **Mass Flow Rate**) for each inlet should correspond to all other inlets that belong to the inlet group.
- The solution begins with an estimated pressure profile at the outlet boundary.

  In general, you can start the solution by assuming that the level of liquid at the outlet corresponds to the level of liquid at the inlet. The convergence and solution time is very dependent on the initial conditions. When the flow is completely subcritical (upstream and downstream), in marine applications for instance, the above approach is recommended.

  If the final conditions of the flow can be predicted by other means, the solution time can be significantly reduced by using the proper boundary condition.
- In the case of super-critical flow at the outlet, you can use the **From Neighboring Cell** option at the outlet, as it may provide better convergence.
- The initialization procedure is very critical in the open channel analysis. Refer to Recommendations for Open Channel Initialization (p. 1429).
- For the initial stability of the solution, a smaller time step is recommended. You can increase the time step once the solution becomes more stable.
- For flows that do not make a transition from sub-critical to super-critical, or vice-versa, you can speed-up the solution calculation by specifying the frequency of Froude number updates during run time by setting the following text command: `solve` → `set` → `open-channel-controls`.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When prompted, set up the following parameter for steady-state flows:

```
/solve/set> open-channel-controls
Iteration interval for Froude number update [10]
```

When prompted, set up the following parameter for transient flows:

```
/solve/set> open-channel-controls
Time step interval for Froude number update [1]
```

- For pure open channel flow applications, the inlet and outlet boundary conditions are controlled by the Froude number. In certain cases, it is possible to impose a hydrostatic profile at the outlet without any Froude number dependency. You can use the following text command: `solve` → `set` → `open-channel-controls`.

  When prompted, set up the following parameter as shown below:

  ```
  /solve/set> open-channel-controls
  Use Froude number independent boundary condition at outlet? [no] yes
  ```

- Relevant open channel inputs, along with the Froude number, can be reported using the following text command: `define` → `boundary-conditions` → `openchannel-threads`.

- In the case of reverse flow, the pressure outlet boundary behaves as a pressure inlet, and the boundary-specific static pressure is taken as the **Total Pressure**. In this case, the static pressure is calculated from the total pressure. You can use the following text command to fix the boundary-specified static pressure, which helps to suppress reflections from the pressure boundary for certain cases: `solve` → `set` → `open-channel-controls`

  When prompted, set up the following parameter as shown below:

  ```
  /solve/set> open-channel-controls
  Use boundary specified static pressure for backflow? [no] yes
  ```

24.3.5. Modeling Open Channel Wave Boundary Conditions

When modeling open channel wave boundary conditions, many of the variables that are used in open channel flow, also exist for open channel wave boundary conditions. You may have to refer to Modeling Open Channel Flows (p. 1410) for information about some of the settings.

To use the open channel wave boundary condition, perform the following:

1. Enable **Gravity** and set the gravitational acceleration fields.

   Setup → **General** **Gravity** → **On**

2. Enable the **Volume of Fluid** model in the **Multiphase Model** dialog box.

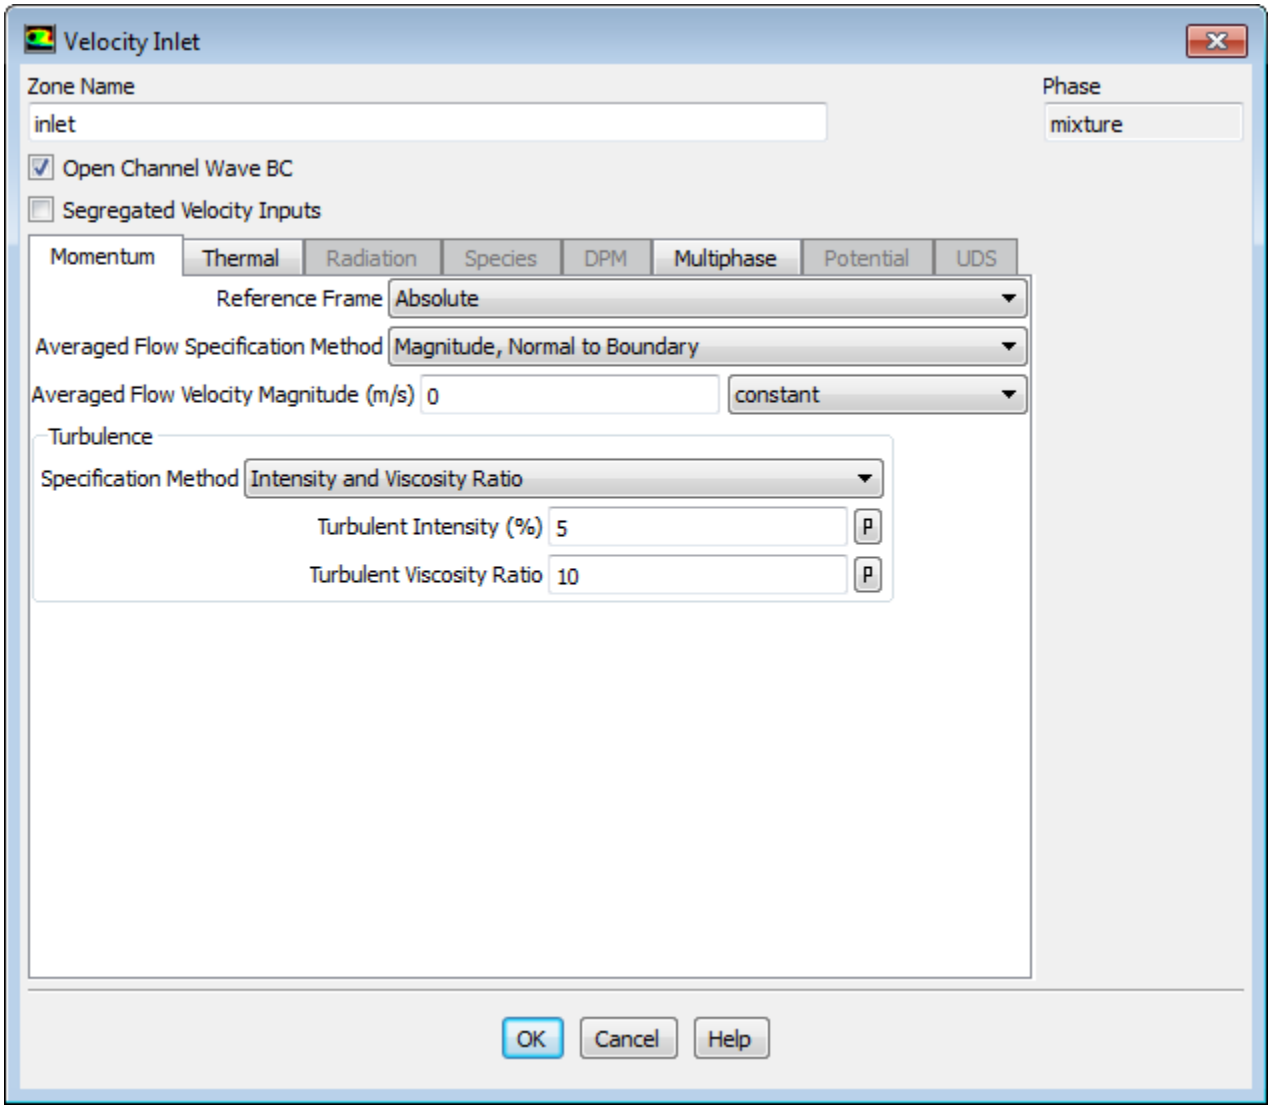
   Setup → **Models** → **Multiphase** → **Edit...**

3. Under **Formulation**, select either **Implicit** or **Explicit**.

4. Under **VOF Sub-Models**, select **Open Channel Wave BC**.

In order to set specific parameters for a particular boundary for open channel wave boundaries, enable the **Open Channel Wave BC** option in the **Velocity Inlet** boundary condition dialog box (Figure 24.21: The Velocity Inlet for Open Channel Wave BC (p. 1420)).

Figure 24.21: The Velocity Inlet for Open Channel Wave BC



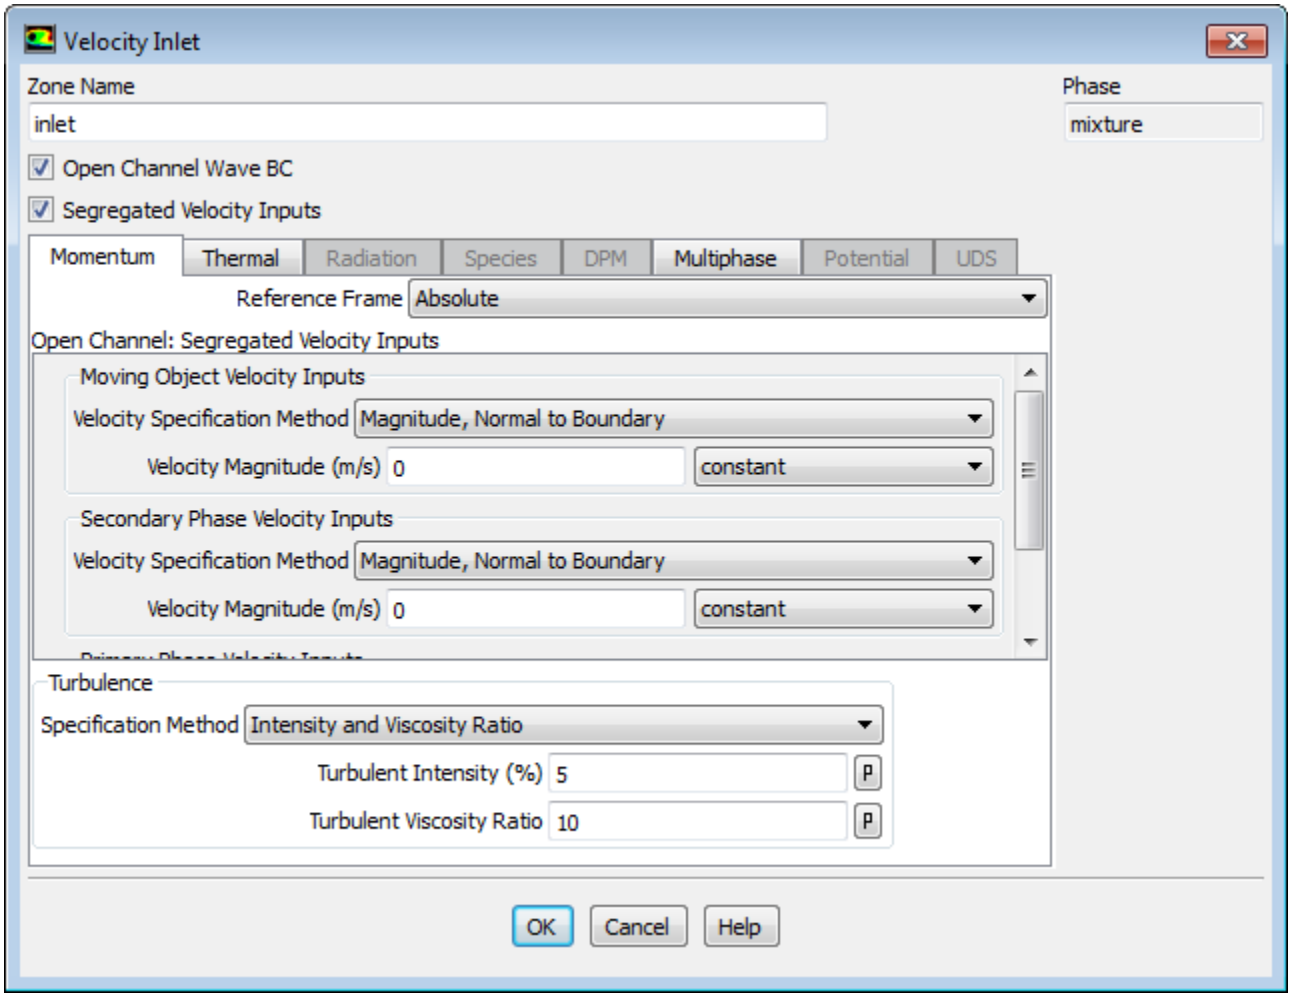
The default method is the **Averaged Flow Specification Method**, where inputs for the moving obstacle and water current are combined. There is no specific treatment for air velocity, which is assumed to be same as the averaged velocity.

Segregated Velocity Inputs

The **Segregated Velocity Inputs** option allows you to prescribe velocity inputs individually for the moving obstacle, Secondary phase (typically water), and Primary phase (typically air).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.22: Segregated Velocity Inputs for Open Channel Wave BC



You can set the moving object and secondary phase velocity specification methods as:

- Magnitude and direction vector
- Magnitude and normal to boundary

You can set the primary phase velocity specification methods as:

- Magnitude and direction vector
- Magnitude and normal to boundary
- Power law and direction vector
- Power law and normal to boundary

Power Law

$$\frac{V}{V_{ref}} = \left(\frac{z}{z_{ref}}\right)^{\alpha} \tag{24.5}$$

Where z_{ref} is the vertical distance from the instantaneous free surface level at which the reference velocity magnitude, V_{ref} is specified. z is the vertical distance from the free surface level at which,

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

velocity V must be estimated. α is the power law coefficient, which is typically 0.16 for an open sea.

Setting Buffer Layer Height

The buffer layer is assumed to be the layer above the free surface, in which the effect of air is not felt. This option is provided by assuming that the air in the vicinity of free surface blows with the speed of the water and the waves, so that direct effect of air is not felt in the wave propagation.

There are two options for providing the buffer height:

1. **Automatic:** the buffer layer is taken as the specified fraction of the maximum wave height.
2. **User-defined:** you provide the input for the buffer layer height.

The buffer layer can also be defined using the following text command:

```
/solve/set> open-channel-wave-options

/solve/set/open-channel-wave-options>
set-buffer-layer-ht     set-verbosity           stokes-wave-variants

/solve/set/open-channel-wave-options> set-buffer-layer-ht
buffer layer specification method (0 - Automatic, 1 - User-defined)  [0]
fraction of buffer layer height to maximum wave height [0.02]

/solve/set/open-channel-wave-options> set-buffer-layer-ht
buffer layer specification method (0 - Automatic, 1 - User-defined)  [0] 1
enter the value of buffer layer height [0]
```

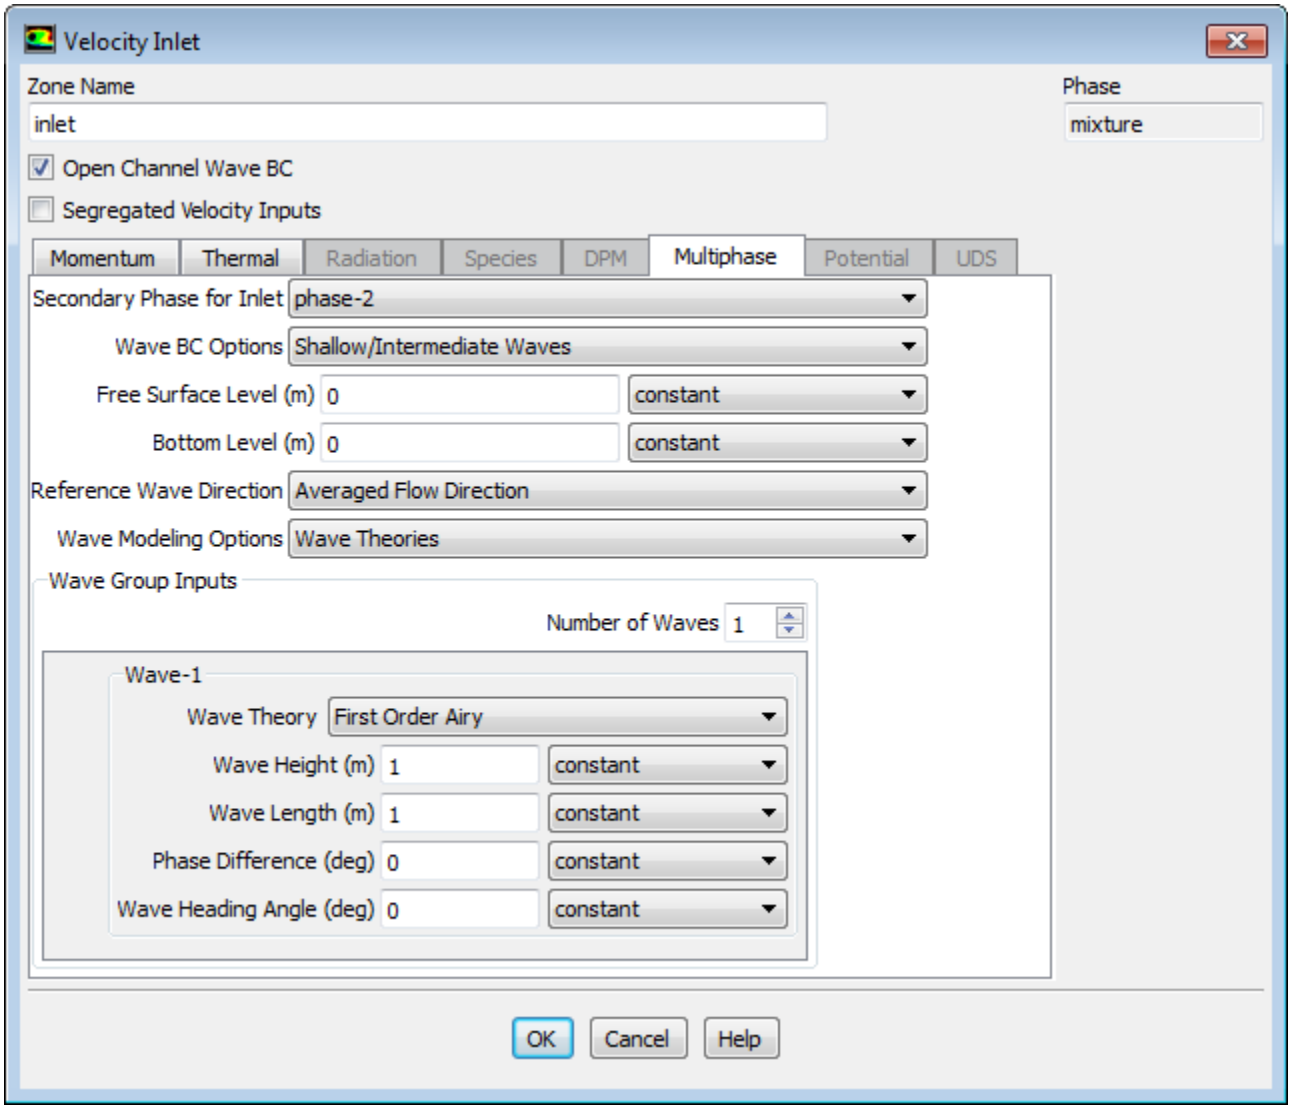
In the **Momentum** tab of the **Velocity Inlet** dialog box, you can enter the averaged flow velocity, which includes components from the flow current and the moving object. You can specify the **Averaged Flow Specification Method** as:

- **Magnitude and Direction**
- **Magnitude and Normal to Boundary**
- **Components**

In the **Multiphase** tab (Figure 24.23: The Velocity Inlet for Open Channel Wave BC (p. 1423)), you will specify the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.23: The Velocity Inlet for Open Channel Wave BC



- **Secondary Phase for Inlet** specifies the phase to which the wave parameters are applied. In case of a three-phase flow, select the corresponding secondary phase from this list.
- **Wave BC Options** of which you have a choice of **Shallow/Intermediate Waves**, **Short Gravity Waves**, **Shallow Waves**, and **None** (for calm sea or pure open channel flow problems without waves). Information about these waves is available in Open Channel Wave Boundary Conditions in the Theory Guide. Note that the short gravity waves expression is derived under the assumption of infinite liquid height.
- **Free Surface Level** is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410).
- **Bottom Level** is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410), and is valid only for shallow or intermediate depth waves. The bottom level is used for calculating the liquid height.
- **Reference Wave Direction** is the direction of wave propagation with zero wave heading angle. You can specify the wave propagation direction as:
  - **Averaged Flow Direction**: In this case, the reference direction is the same as the averaged flow direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - **Direction Vector**
  - **Normal to Boundary**

- **Wave Modeling Options** determines how the waves are modeled in the shallow/intermediate and short gravity wave regimes. You can choose to model the waves using either **Wave Theories** or **Wave Spectrum**. **Wave Theories** is usually selected for simulating regular waves. To simulate random waves, select **Wave Spectrum**.
- Depending on your choice of **Wave BC Options** and **Wave Modeling Options**, you will need to specify the wave parameters as described in the following sections.

Shallow Wave Inputs (p. 1424)
Wave Group Inputs (p. 1425)
Wave Spectrum Inputs (p. 1425)

Shallow Wave Inputs

If you have selected **Shallow Waves** for **Wave BC Options** you can specify the following settings for each wave:

Number of Waves
is the option to set the number of interacting waves (default = 1)

Ideally, shallow waves do not support the principle of superposition. The **Number of Waves** option enables interaction of two different waves originating at unique (non-interfering) locations within the domain. Collision of two counter-propagating solitary waves inside a domain is an example of a shallow wave interaction.

Wave Theory
of which you have a choice of **Fifth Order Solitary** (the default) and **Fifth Order Cnoidal**. Information about the types of wave theory is available in Open Channel Wave Boundary Conditions in the Theory Guide.

Wave Height
is the height difference between a wave crest to the neighboring trough.

Since a solitary wave does not have troughs, the wave height is the distance between a wave crest to mean free surface level.

Wave Length
is the distance between two consecutive zero crossings.

Since solitary waves are derived based on the assumption of infinite wave length, specified wave length is only used to estimate the elliptic function parameter for suitability of the wave theory, and is not used in calculating wave parameters.

Inlet Offset Distance
is the translational distance from the reference point origin in the reference wave propagation direction. This option is used to generate a wave from a location other than the reference frame origin. For a solitary wave, the hump is always generated at the location where:

$$x - x_0 = 0 \tag{24.6}$$

where x and x_0 are spatial coordinates in the reference wave propagation direction.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Wave Heading Angle
is the angle between the direction of the wavefront and the reference wave propagation direction, in the plane of the flow surface. In 2D, there are only two possibilities, zero degree when the wave is in the reference propagation direction, and 180 degree when the wave Is in the direction opposite to the reference propagation direction.

Wave Group Inputs

If you have selected **Wave Theories** for **Wave Modeling Options** you can specify the following settings for each wave:

Number of Waves
is the option to set the number of superposed waves (default = 1)

Wave Theory
of which you have a choice of **First Order Airy** (the default), **Second Order Stokes**, **Third Order Stokes**, **Fourth Order Stokes**, and **Fifth Order Stokes**. Information about the types of wave theory is available in Open Channel Wave Boundary Conditions in the Theory Guide.

Wave Height
is the height difference between a wave crest to the neighboring trough.

Wave Length
is the distance between two consecutive crests, troughs or zero crossings.

Phase Difference
is the phase angle by which one periodic disturbance or wavefront lags behind or precedes another in time or space.

Wave Heading Angle
is the angle between the direction of the wavefront and the reference wave propagation direction, in the plane of the flow surface. In 2D, there are only two possibilities, zero degree when the wave is in the reference propagation direction, and 180 degree when the wave Is in the direction opposite to the reference propagation direction.

Wave Spectrum Inputs

If you have selected **Wave Spectrum** for **Wave Modeling Options** you can specify the following settings for each wave:

Frequency Spectrum Method
specifies the spectrum to use. You can select **Pierson-Moskowitz** (appropriate for fully-developed seas), **Jonswap** (appropriate for fetch-limited seas), or **TMA** (appropriate for fetch-limited, finite-depth seas).

Peak Shape Parameter
controls the shape and amplitude of the frequency peak in the **Jonswap** and **TMA** formulations. This corresponds to γ in Equation 17.100 in the *Fluent Theory Guide*.

Significant Wave Height
is the mean wave height of the largest 1/3 of waves. This corresponds to H_s in Equation 17.99 in the *Fluent Theory Guide*.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Peak Wave Frequency
is the wave frequency corresponding to the highest wave energy. This corresponds to ω_p in Equation 17.99 and Equation 17.100 in the *Fluent Theory Guide*. ω_p can be expressed in terms of the peak wave period, T_p, as $\omega_p = {}^{2\pi}/_{T_p}$.

Minimum/Maximum Wave Frequency
specify the frequency range for the spectrum. Note that the **Peak Wave Frequency** must fall in between **Minimum Wave Frequency** and **Maximum Wave Frequency**.

Number of Frequency Components
specifies the number of components into which the frequency spectrum is divided.

Direction Spreading Method
specifies the method to use for specifying the directional spreading characteristics. You can choose **Uni-directional** (for long-crested waves), **Frequency Independent Cosine Function** (for short-crested waves where the directional component does not depend on frequency), and **Frequency Dependant Hyperbolic Function** (for short-crested waves where the directional component depends on frequency).

Frequency Independent Cosine Exponent
specifies the exponent in the Frequency Independent Cosine Function formulation. This corresponds to s in Equation 17.104 in the *Fluent Theory Guide*.

Mean Wave Heading Angle
specifies the principal wave heading direction.

Angular Spread
specifies the deviation from the mean wave direction for calculating the angular range.

Number of Angular Components
specifies the number of components into which the angular range is divided.

The total number of wave components is the product of **Number of Frequency Components** and **Number of Angular Components**. For modeling random waves, phase differences for the individual wave components are randomly distributed between 0 and 2π.

Note

Any change in the input for **Number of Wave Components** will change the values of phase difference for each component. Therefore, it is recommended that you start the simulation from a saved case file after setting all the wave spectrum user inputs and that you not change the number of wave components during the simulation.

24.3.5.1. Summary Report and Regime Check

A useful text command used to print out a summary of the open channel wave boundary condition settings is `define/boundary-conditions/open-channel-wave-settings`. The output will depend on whether you have chosen **Wave Theories** or **Wave Spectrum**.

Sample Output for Wave Theories

```
/define/boundary-conditions> open-channel-wave-settings

Wave Input Analysis for Velocity Inlet : Thread ID = 5

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Wave-1 Analysis
**************************************

Current Settings :
------------------
Wave theory : 5th-order-Stokes , Wave regime = Shallow/Intermediate
Wave Height (H) = 0.2160, Wave Length (L) = 1.9400
Liquid Depth (h) = 0.6000, Ursell Number (H*L*L/(h*h*h)) = 3.7636

Mandatory checks for full wave regime within wave breaking limit
-----------------------------------------------------------------
Relative Height: H/h = 0.3600 , Maximum theoretical limit = 0.7800
Maximum numerical limit = 0.5500
Relative height within wave breaking limit

Wave Steepness: H/L = 0.1113 , Maximum theoretical limit = 0.1420
Stable numerical limit = 0.1000 , Maximum numerical limit = 0.1200
Warning: Wave steepness exceeding the stable numerical limit.
Waves could be stable or unstable in this regime.

Checks for selected wave theory within wave breaking and stability limit
-------------------------------------------------------------------------
Relative height check
H/h = 0.3600 , Min : 0.0000 , Max : 0.5000
Relative height check : successful

Wave Steepness check
H/L = 0.1113 , Min : 0.0000 , Max : 0.1363
Wave steepness check : successful

Ursell Number check
Ur = 3.7636 , Min : 0.0000 , Max : 25.0000
Ursell number check : successful

Wave regime check
h/L = 0.3093 , Min : 0.0600 , Max : 10000.0000
Wave regime check : successful

Summary
----------------------
Checks : passed
Selected wave theory is appropriate for application.
```

Sample Output for Wave Spectrum

```
Wave Input Analysis for Velocity Inlet : Thread ID = 6
*******************************************************

Wave Spectrum Analysis
**************************************

Current Settings :
------------------
Frequency Spectrum : Jonswap
Direction Spreading Method : Unidirectional

Significant Wave Height (Hs) = 5.0000
Peak Wave Frequency (wp) = 1.0000, Peak Time Period (Tp) = 6.2832
Minimum Frequency (wi) = 0.6600, Maximum Frequency (we) = 1.6600

Wave Lengths at Min/Peak/Max frequencies (Li, Lp, Le) = (141.5015, 61.6380, 22.3683)

Recommendation: Set the min and max wave frequencies so that most of the wave energy
  is concentrated in the selected regime of spectrum.
  - Min frequency = 0.5*Peak frequency
  - Max frequency = 2.5*Peak frequency

Wave Regime Check
----------------------
Wave regime type = Short Gravity (Deep)
```

```
Information: Validity of short gravity assumption : Liquid Depth > 0.5*Max Wave Length

Sea Steepness Check
-----------------------
Peak Time Period (Tp) = 6.2832
Zero Upcrossing Time Period (Tz) = 4.7869

Sea Steepness based on Tp (Sp) = 0.0811, Steepness Limit = 0.0667
Sea Steepness based on Tz (Sz) = 0.1398, Steepness Limit = 0.1000

Warning: Sea Steepness based on peak time period exceeding limit.
Warning: Sea Steepness based on zero upcrossing time period exceeding limit.

Information: High wave steepness of any individual component too could affect the wave pattern,
  as superposition of wave components is based upon lienar wave theory.

Frequency Spectrum Check
--------------------------
Peak Time Period to Wave Ht Sqrt Ratio (r = Tp/sqrt(Hs)) = 2.8099

Message: Selection of Jonswap spectrum is appropriate.

Recommended value of Peak Shape Parameter for r <= 3.6 :  5.0000

Spectrum Resolution check
---------------------------
Number of frequency components = 50
Number of angular components = 1
Total number of wave components = 50

Information: Higher number of wave components would have adverse effect on speed-up
  whereas smaller could affect the accuracy by not resolving the spectrum well.
  Following steps could assist to optimize the number of components
  1. Set number of frequency/angular components in boundary condition panel,
  2. Set TUI command solve> set> open-channel-wave-verbosity to 2 before initialization,
  3. Initialize (It would print Spectrum Energy for each frequency/angle.)
  4. Copy the information to plot Sw vs Omega and S_theta vs theta
  5. Optimize the number of components after repeating steps 1-4
```

24.3.5.2. Transient Profile Support for Wave Inputs

ANSYS Fluent supports transient profiles for all wave inputs using user-defined functions as seen by the example below:

```
/************************************************************************
  UDF for defining transient profile wave inputs
 ************************************************************************/

#include "udf..h"

#define H 0.02 /* wave height for both waves : same */
#define LEN1 3. /* wave length for first wave */
#define LEN2 6. /* wave length for second wave*/
#define G 9.81
#define D 10. /* liquid depth */
#define U 1. /* wave current */
#define X 0. /* inlet point */

DEFINE_TRANSIENT_PROFILE(wave_ht, current_time)
{
 real k1 = 2.*M_PI/LEN1;
 real k2 = 2.*M_PI/LEN2;
 real w1 = sqrt(G*k1*tanh(k1*D)) + k1*U;
 real w2 = sqrt(G*k2*tanh(k2*D)) + k2*U;
 real dk = 0.5*(k1 - k2);
 real dw = 0.5*(w1 - w2);
 return (2.*H*cos(dk*X - dw*current_time));
}
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.3.5.3. Alternative Stokes Wave Theory Variant

Fluent uses Fenton's formulation for Stokes theories by default. For additional information about the current Stokes theories formulation, see Stokes Wave Theories in the *Fluent Theory Guide*. To revert to the old formulation, provided by Skjebreia and Hendrickson, use the following text command:

```
/solve/set/open-channel-wave-options>
set-buffer-layer-ht     set-verbosity           stokes-wave-variants

/solve/set/open-channel-wave-options> stokes-wave-variants
Use Fenton's formulation for Stokes wave theories [yes] no
Activating old formulation (Skjelbreia and Hendrickson) for Stokes wave theories.
```

For additional information on the old formulation, refer to Lin's book [59] (p. 2890).

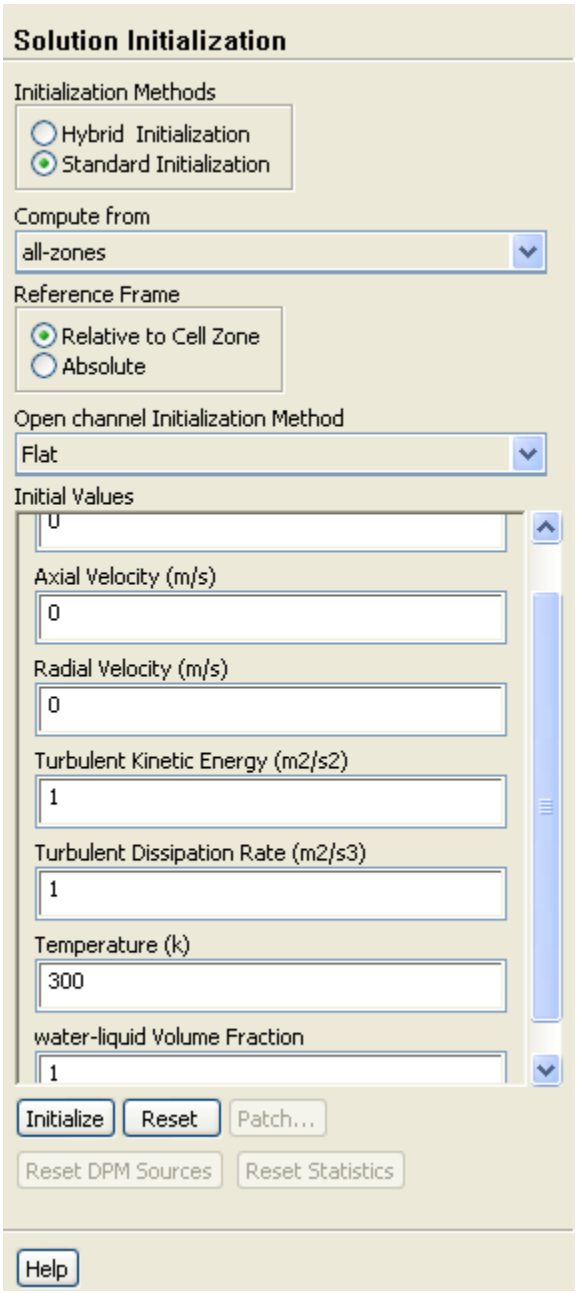
24.3.6. Recommendations for Open Channel Initialization

Once you have selected either the **Open Channel Flow** or the **Open Channel Wave BC** option in the **Multiphase Model** dialog box, then the **Open Channel Initialization Method** drop-down list appears in the **Solution Initialization** task page.

Solution → **Initialization**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.24: The Solution Initialization Task Page



Select an inlet zone from the **Compute from** drop-down list. You can now make your selection from the **Open Channel Initialization Method** drop-down list. If only the **Open Channel Flow** option was enabled, then you only have a choice of **None** or **Flat**. If you enabled **Open Channel Wave BC**, then your choices are **None**, **Flat**, or **Wavy**. The default initialization method is **None**.

If you initialize the solution using **None**, it has no effect as it does not use any open channel information from the selected zone. The **Open Channel Initialization Method** comes into effect when you select either **Flat** or **Wavy**.

Important

This initialization is only valid for pressure-inlets, pressure outlets, and mass-flow inlets for open channel flow and velocity inlets for open channel wave boundary conditions. If the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

selected inlet zone does not have either open channel flow or open channel wave boundary conditions, ANSYS Fluent will report an error message after you initialize the flow with open channel initialization method of **Flat** or **Wavy**.

For open channel initialization from the pressure outlet boundary, the hydrostatic pressure profile based on the **Free Surface Level** is patched in the domain. The volume fraction in the domain is patched based on **Free Surface Level** provided at the pressure outlet boundary. To patch velocity and other variables, the values in the **Solution Initialization** task page will be used.

Important

- Open channel initialization from the pressure outlet boundary is only supported for two phase flow.
- The pressure specification methods, with the exception of **Free Surface Level**, are not supported for open channel initialization from the pressure outlet boundary.

Initialization will result in the volume fraction, X, Y, and Z velocities, and pressure being patched in the domain. The volume fraction will be patched in the domain based on the free surface level of the selected zone from the **Compute from** list. The velocities in the domain will be patched assuming the constant value provided for the velocity magnitude in the selected zone.

Important

If you specify a profile for the velocity magnitude or direction vectors, the initialization will select the value for the velocity magnitude and direction vectors from only one face. Therefore the initialization may be inaccurate. However, generally, open channel inputs for velocity magnitude and direction vectors are constant.

The pressure that is patched is the hydrostatic pressure based on the free surface level specified in the selected zone.

You can use the following text command for open channel automatic initialization:

`solve` → `initialize` → `open-channel-auto-init`

When prompted, set up the following parameters:

boundary thread id
Enter the thread id for the boundary to be selected for open channel automatic initialization.

flat free surface initialization
This option is available for both open channel flow and open channel wave boundary conditions.

wavy free surface initialization
This option appears only for open channel wave boundary conditions, when flat free surface initialization is not selected.

The steps to be followed for open channel automatic initialization are

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Compute defaults based on valid open channel boundary thread. This step is required for better initialization of turbulence parameters based on uniform velocity magnitude.

   `solve → initialize → compute defaults`

2. This would provide information about the selected boundary and type of initialization.

   `solve → initialize → open-channel-auto-init`

3. Initialize

   `solve → initialize → initialize`

24.3.6.1. Reporting Parameters for Open Channel Wave BC Option

To report values as wave speed, wave frequency, and time period for individual waves during initialization, you can set the following text command:

`solve → set → open-channel-wave-options → set-verbosity`

When prompted to set `Verbosity for reporting of derived wave inputs during initialization`, enter `1` as shown below:

Note

You can enter values of 0, 1, or 2. Entering a higher number provides more information.

```
/solve/set/open-channel-wave-options> set-verbosity

Verbosity for reporting of derived wave inputs during initialization
 [0] 1
```

A sample of the resulting output for wave groups after initializing is shown below:

```
Wave-1 : Wave Height = 0.0200, Wave Length = 3.0000
Wave Number = 2.0944, Wave Speed = 2.1642, Wave Frequency = 4.5328
Effective parameters: Wave Speed = 3.1642, Wave Frequency = 6.6272, Time Period = 0.9481

Wave-2 : Wave Height = 0.0200, Wave Length = 6.0000
Wave Number = 1.0472, Wave Speed = 3.0607, Wave Frequency = 3.2052
Effective parameters: Wave Speed = 4.0607, Wave Frequency = 4.2524, Time Period = 1.4776

Time Period based on average effective frequency: 1.1550
```

The resultant output for **Shallow Waves** option is shown below:

```
Wave-1 : Wave Height = 0.2400, Specified Wave Length = 16.0000
Wave Number = 0.5051, Estimated Wave Length = 12.4398
Elliptic Function Parameter (m) : Calculated = 0.9976, Used = 1.0000
Liquid Height = 0.8000, Trough Height = 0.800000
Wave Speed = 3.1868, Wave Frequency = 1.6096
Effective parameters: Wave Speed = 4.1868, Wave Frequency = 2.1147
Time Period based on effective frequency: 2.9712
```

24.3.7. Numerical Beach Treatment for Open Channels

In certain applications, it is desirable to suppress numerical reflection near the outlet boundary for wave dampening. To understand the theory involved in this application, refer to Numerical Beach Treatment.

To include numerical beach in your simulation, perform the following:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Enable **Gravity** and set the gravitational acceleration fields.

   Setup → **General** → **Gravity** → **On**

2. Enable the **Volume of Fluid** model in the **Multiphase Model** dialog box.

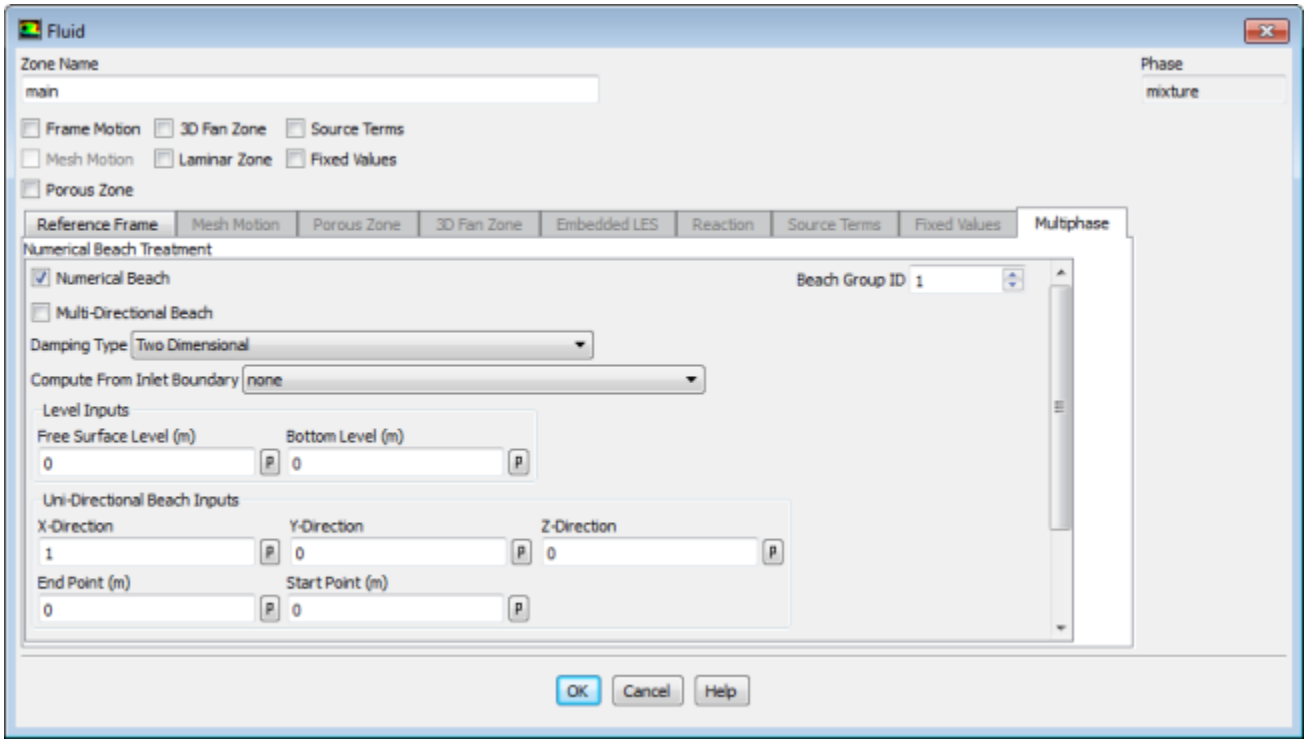
   Setup → **Models** → **Multiphase** → **Edit...**

3. Under **Scheme**, select either **Implicit** or **Explicit**.

4. Select **Open Channel Flow** and/or **Open Channel Wave BC**.

In order to set the numerical beach parameters for a fluid zone, go to the **Fluid** dialog box (Figure 24.25: The Fluid Dialog Box to Enable Numerical Beach (p. 1433)).

Figure 24.25: The Fluid Dialog Box to Enable Numerical Beach



In the **Multiphase** tab of the **Fluid** dialog box, enable the **Numerical Beach** option and enter the following:

- **Beach Group ID** represents the cell zones sharing the damping length containing the same input parameters.
- **Multi-Directional Beach** helps to suppress the numerical reflections that arise from multiple open-channel pressure outlet boundaries. This is desirable while modeling oblique waves or when the pressure-outlet boundaries are closer to the zone of interest. (Only available for 3D problems.)
- **Uni-Directional Beach:** should be used to suppress the numerical reflections from a single open channel pressure outlet. This is the case when the flow is generally uni-directional.
- **Damping Type** allows you to choose between **Two Dimensional** and **One Dimensional**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - **Two Dimensional** is the damping treatment in the beach and gravity direction.
  - **One dimensional** is the damping treatment in the beach direction.

- **Compute From Inlet Boundary** is set to **none** by default. If there are available open channel boundaries (velocity-inlet, pressure-inlet, and mass-flow-inlet), boundary names are added to the drop-down list. If you select a boundary from the list, the **Level Inputs**, **Uni-Directional Beach Inputs** or **Multi-Directional Beach Inputs** in beach direction, and **Damping Resistance** values will be updated in the interface. You have the option to overwrite the updated inputs with values that are more applicable to your simulation.
- **Level Inputs** is only available for the **Two Dimensional** damping type.
  - **Free Surface Level** is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410).
  - **Bottom Level** is the same definition as for open channel flow, see Modeling Open Channel Flows (p. 1410). During the automatic calculation from the velocity inlet boundary for short gravity waves, this parameter is updated under some assumptions, as noted in Solution Strategies (p. 1435). The bottom level is used for calculating the liquid height.

Numerical Beach Inputs

Numerical beach is assumed as a rectangular domain, where its end-plane (outer surface) is an open channel pressure outlet boundary and start-plane is a plane parallel to a pressure outlet. Beach direction is assumed as the direction normal to a pressure outlet. Damping length is the normal distance between the end and start plane.

Uni-Directional Beach Inputs:

X, **Y**, and **Z** are the vector components of the beach outward normal (typically normal to the nearest pressure outlet).

The end point is calculated by taking the dot product of beach direction with any point lying on the end plane. Similarly, the start point is calculated as the dot product of beach direction with any point lying on the start-plane.

Note

The automatically calculated value of the end point is assumed based on the domain extents for all of the cell zones. Enter your own value if required.

Damping Length Specification is only available if **Open Channel Wave BC** is enabled in the **Multiphase Model** dialog box. There are two options you can choose from:

- **End Point and Wave Lengths** (default).
- **End and Start Points** are the limits of the damping zone.

Multi-Directional Beach Inputs

- **Number of Beach**

  The default is 2, the maximum is 3.

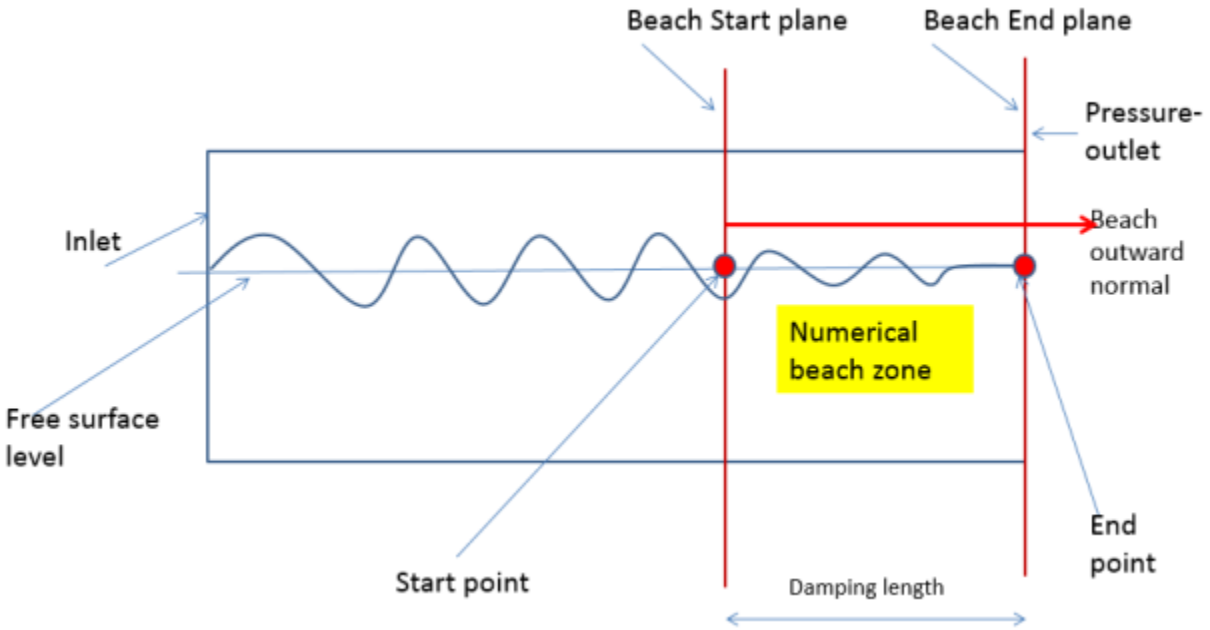
- **X-Direction**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Y-Direction**
- **Z-Direction**
- **End Point**
- **Damping Length**

See Figure 24.26: Numerical Beach Sketch (p. 1435) for a visual representation of the numerical beach.

Figure 24.26: Numerical Beach Sketch



- **Relative Velocity Resistance Formulation** calculates the source term using relative velocities in the numerical beach zone when using moving/deforming meshes or moving reference frames.
- **Linear Damping Resistance** is the resistance per unit time.
- **Quadratic Damping Resistance** is the resistance per unit length.

24.3.7.1. Solution Strategies

Below are some helpful key points when using the **Numerical Beach** option:

1. The **Compute from Inlet Boundary** drop-down list is a convenient feature as it provides automatic inputs, which you should check to make sure the values are reasonable. Some of the provided values are calculated under certain assumptions:

   a. The bottom level, in the case of short gravity waves, is selected in the velocity inlet dialog box for open channel wave boundary conditions. Since there is no user input for this parameter, ANSYS Fluent calculates the bottom level as the value of the free surface level less 2.5 times the wave length. The assumption is that the liquid height is 2.5 times the wave length.

   b. The automatically calculated value of the end point is assumed based on the domain extents for all of the cell zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. For manual inputs of start and end points, you should verify that these points are calculated correctly in the beach direction. To check for their validity, subtracting the start point from the end point should give you a positive value.

3. For manual inputs of **Free Surface Level** and **Bottom Level**, you should verify that these points are calculated correctly in the direction opposite to gravity. To check for their validity, subtracting the bottom level from the free surface level should give you a positive value.

4. In case you create separate damping zones, but the damping length is not sufficient to suppress the waves, clubbing of the beach could be done by selecting the same beach ID for other cell zones. In this case, both the cell zones would share the same information.

5. In case of separate damping zones (without clubbing), you should verify that the damping length is more than or equal to the specified number of wave lengths for the calculation of the start point.

6. Damping resistance should be chosen carefully as too much or too little damping could affect the wave profiles in a no-damping zone. The **Compute From Inlet Boundary** option automatically populates the values for damping resistances based on analytical correlations for wave energy. However, you may need to further tune these values for certain cases if the computed values are found to be unsuitable.

7. Steep damping at the beginning of the damping zone could affect the wave profile just before the damping zone.

8. It is recommended that you use a coarse mesh in the damping zone with increased coarseness towards the end of the damping zone.

24.3.8. Defining the Phases for the VOF Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction in a VOF calculation are provided below.

Important

In general, you can specify the primary and secondary phases whichever way you prefer. It is a good idea, especially in more complicated problems, to consider how your choice will affect the ease of problem setup. For example, if you are planning to patch an initial volume fraction of 1 for one phase in a portion of the domain, it may be more convenient to make that phase a secondary phase. Also, if one of the phases is a compressible ideal gas, it is recommended that you specify it as the primary phase to improve solution stability.

24.3.8.1. Defining the Primary Phase

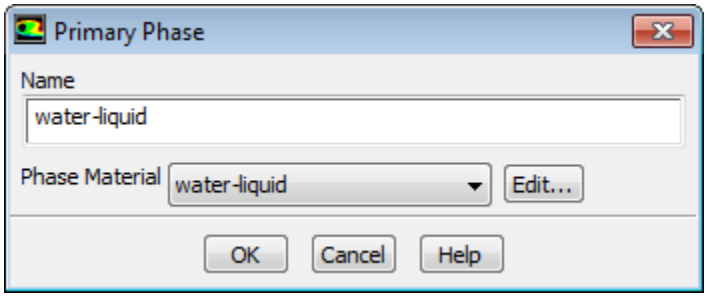
To define the primary phase in a VOF calculation, perform the following steps:

1. Select **phase-1** in the **Phases** list.

2. Click **Edit...** to open the **Primary Phase** dialog box (Figure 24.27: The Primary Phase Dialog Box (p. 1437)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.27: The Primary Phase Dialog Box



3. In the **Primary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**.

   a. Click **Edit...**, and the **Edit Material** dialog box will open.

   b. In the **Edit Material** dialog box, check the properties, and modify them if necessary. (See Physical Properties (p. 459) for general information about setting material properties, Modeling Compressible Flows (p. 1375) for specific information related to compressible VOF calculations, and Modeling Solidification/Melting (p. 1447) for specific information related to melting/solidification VOF calculations.)

   Important

   If you make changes to the properties, remember to click **Change** before closing the **Edit Material** dialog box.

6. Click **OK** in the **Primary Phase** dialog box.

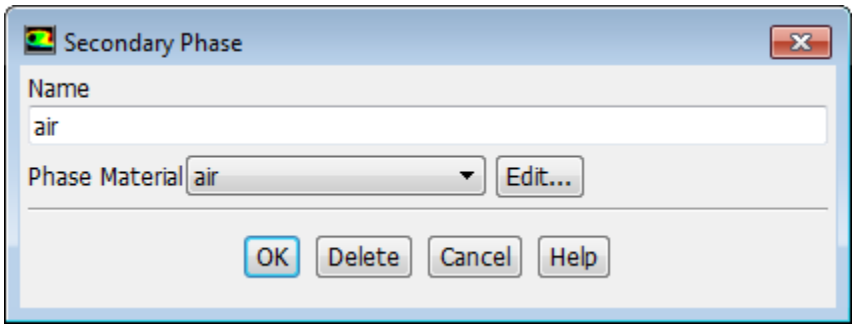
24.3.8.2. Defining a Secondary Phase

To define a secondary phase in a VOF calculation, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.

2. Click **Edit...** to open the **Secondary Phase** dialog box (Figure 24.28: The Secondary Phase Dialog Box for the VOF Model (p. 1437)).

Figure 24.28: The Secondary Phase Dialog Box for the VOF Model



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**, following the procedure outlined above for setting the material properties for the primary phase.

6. Click **OK** in the **Secondary Phase** dialog box.

24.3.8.3. Including Surface Tension and Adhesion Effects

As discussed in When Surface Tension Effects Are Important in the Theory Guide, the importance of surface tension effects depends on the value of the capillary number, Ca (defined by Equation 17.31 in the Theory Guide), or the Weber number, We (defined by Equation 17.32 in the Theory Guide). Surface tension effects can be neglected if $\mathrm{Ca} \gg 1$ or $\mathrm{We} \gg 1$.

Several surface tension options are provided through the text user interface (TUI) using the `solve/set/surface-tension` command :

`solve` → `set` → `surface-tension`

The `surface-tension` command prompts you for the following information:

- whether you require node-based smoothing

  The default value is `yes`, indicating that node-based smoothing will be used. Note that if you are reading in a case that was created in versions prior to ANSYS Fluent 13, then cell-based smoothing will be used by default for the VOF calculations.

- the number of smoothings

  The default value is `1`. A higher value can be used in case of tetrahedral and triangular meshes in order to reduce any spurious velocities.

- the smoothing relaxation factor

  The default is `1`. This is useful in the cases where VOF smoothing causes a problem (for example, liquid enters through the inlet with wall adhesion on).

- whether you want to use VOF gradients at the nodes for curvature calculations

  With this option, ANSYS Fluent uses VOF gradients directly from the nodes to calculate the curvature for surface tension forces. The default is `yes` which produces better results with surface tension compared to gradients that are calculated at the cell centers.

Important

Note that the calculation of surface tension effects will be more accurate if you use a quadrilateral or hexahedral mesh in the area(s) of the computational domain where surface tension is significant. If you cannot use a quadrilateral or hexahedral mesh for the entire domain, then you should use a hybrid mesh, with quadrilaterals or hexahedra in the affected areas.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

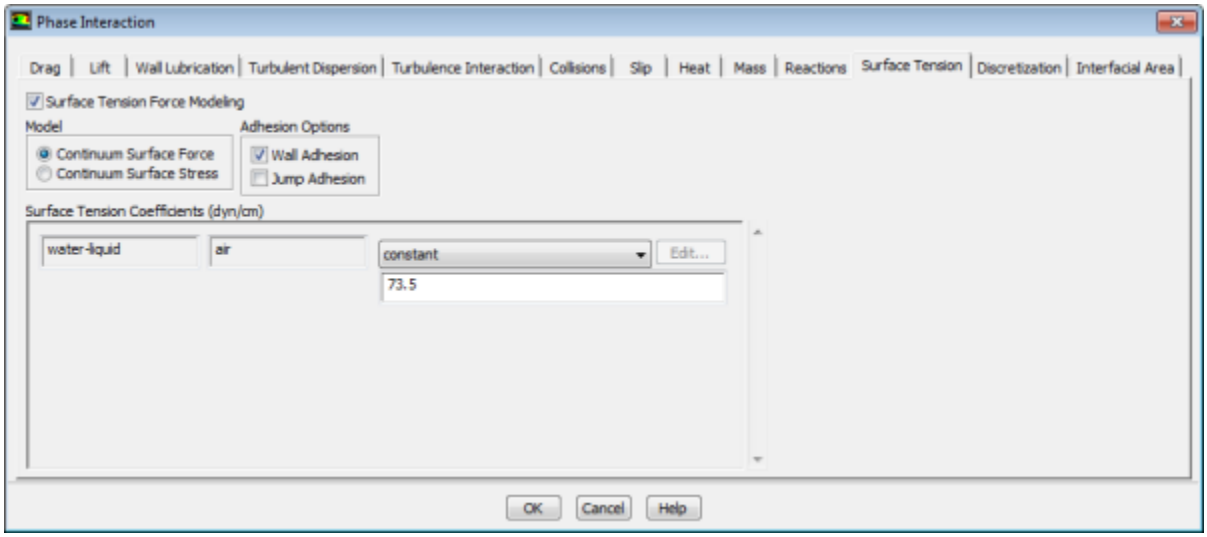
ANSYS Fluent uses node based smoothing for smoothed volume fraction and node based gradients for smoothed curvature calculation to provide better accuracy and robustness.

Important

Pressure jump caused by the surface tension is discontinuous in nature, and also it acts locally at the interface. These numerical difficulties are overcome in an approximate manner by considering the smoothed distribution of the volume fraction field within the finite interfacial width. Smoothing procedures, in general, are mesh dependent. Therefore, the amount and nature of the smoothing procedure could have a significant effect on the results for surface tension cases.

If you want to include the effects of surface tension along the interface between one or more pairs of phases, as described in Surface Tension and Adhesion in the Theory Guide, click **Interaction...** to open the Phase Interaction Dialog Box (p. 2363) (Figure 24.29: The Phase Interaction Dialog Box for the VOF Model (Surface Tension Tab) (p. 1439)).

Figure 24.29: The Phase Interaction Dialog Box for the VOF Model (Surface Tension Tab)



Perform the following steps to model surface tension (and, if appropriate, include adhesion) effects along the interface between one or more pairs of phases:

1. Click the **Surface Tension** tab.

2. Enable the **Surface Tension Force Modeling** option to include the surface tension method.

   Note

   Make sure you specify the **Surface Tension Coefficients** as **constant** or **user-defined**. If **none** is selected, then **Surface Tension Force Modeling** will automatically be disabled.

3. Select the surface tension method that is most applicable to your case. You can choose between **Continuum Surface Force** and **Continuum Surface Stress**. Information about each of the methods is described in Surface Tension in the Theory Guide.

4. For each pair of phases between which you want to include the effects of surface tension, specify an input for the surface tension coefficients using one of the following options:

   - Constant Value
   - Temperature-dependent polynomial, piecewise polynomial, or piecewise linear

     Note

     These options are available while modeling energy.

   - User-defined surface tension coefficient

     Note

     This can be defined as a function of any space variable or time.

   See Surface Tension and Adhesion in the Theory Guide for more information on surface tension, and the Fluent Customization Manual for more information on user-defined functions. All surface tension coefficients are equal to 0 by default, representing no surface tension effects along the interface between the two phases.

   Important

   For calculations involving surface tension, it is recommended that you also turn on the **Implicit Body Force** treatment for the **Body Force Formulation** in the **Multiphase Model** dialog box. This treatment improves solution convergence by accounting for the partial equilibrium of the pressure gradient and surface tension forces in the momentum equations. See Including Body Forces (p. 1377) for details.

5. If you want to include wall adhesion, enable the **Wall Adhesion** option. When **Wall Adhesion** is enabled, you will need to specify the contact angle at each wall as a boundary condition (as described in Defining Multiphase Cell Zone and Boundary Conditions (p. 1391)).

   The contact angle θ_w is the angle between the wall and the tangent to the interface at the wall, measured inside the *phase listed in the left column* under **Wall Adhesion** in the **Momentum** tab of the **Wall** dialog box. For example, if you are setting the contact angle between the oil and air phases in the **Wall** dialog box shown in Figure 24.30: The Wall Dialog Box for a Mixture in a VOF Calculation with Wall Adhesion (p. 1441), θ_w is measured inside the oil phase, as seen in Figure 24.31: Measuring the Contact Angle (p. 1442). For more information, refer to Wall Adhesion in the Theory Guide.

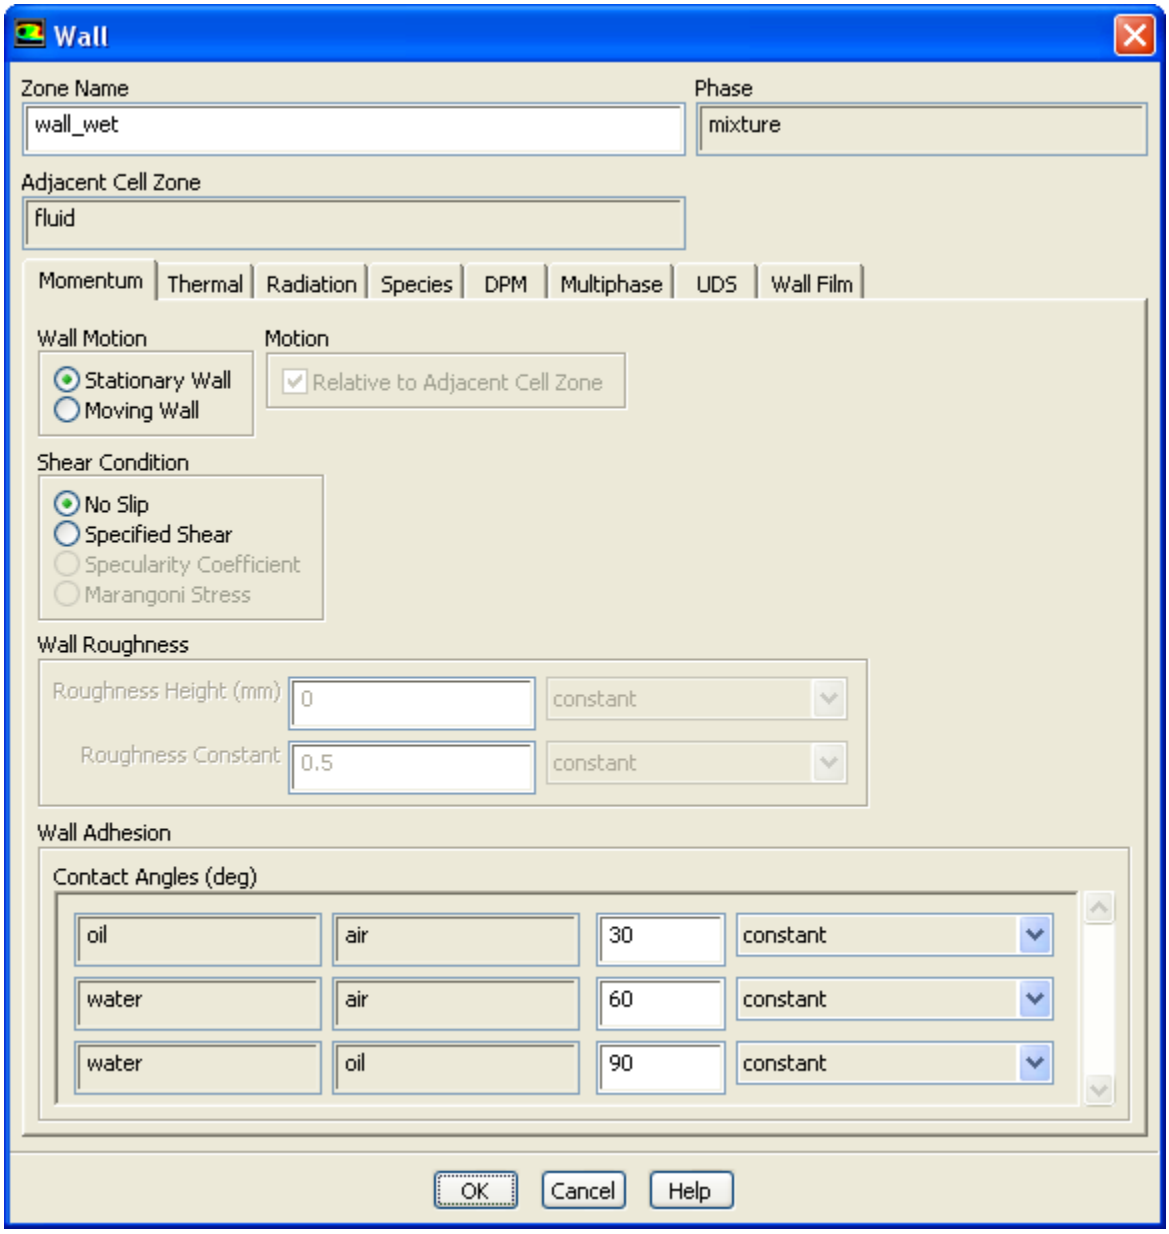
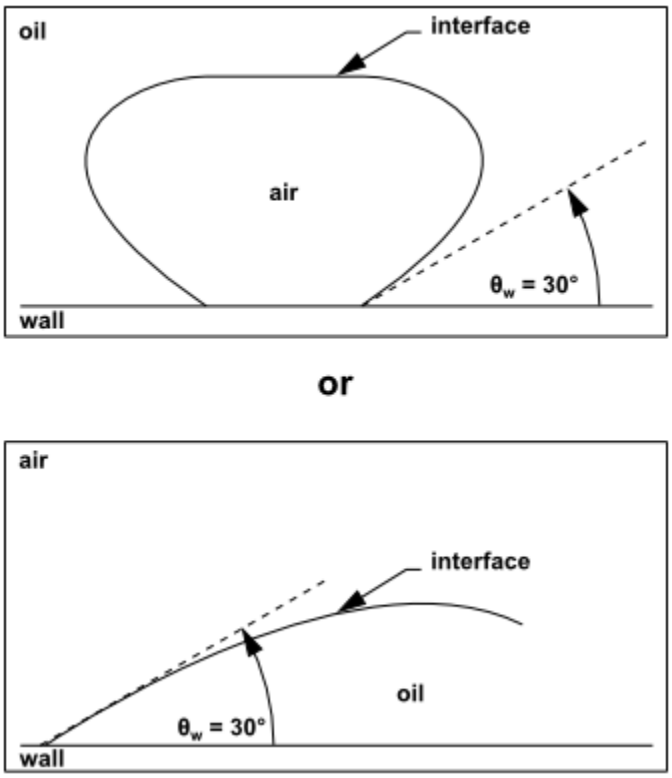
Figure 24.30: The Wall Dialog Box for a Mixture in a VOF Calculation with Wall Adhesion



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.31: Measuring the Contact Angle



6. If you want to include jump adhesion, enable the **Jump Adhesion** option. When **Jump Adhesion** is enabled, you will need to specify the contact angle at the porous jump in the **Porous Jump** dialog box (as described in Defining Multiphase Cell Zone and Boundary Conditions (p. 1391)). The contact angle specification and measurement for jump adhesion is similar to that of wall adhesion (as explained in step 3 above).

Important

Jump adhesion only supports the cell based smoothing option for surface tension. When the **Jump Adhesion** option is enabled in the **Phase Interaction** dialog box, the correct settings are automatically set for surface tension. To view the surface tension settings, use the `solve/set/surface-tension` text command.

Note

The following limitations exist:

- When the **Wall Adhesion** and **Jump Adhesion** options are enabled, you must specify a nonzero surface tension coefficient.
- **Jump Adhesion** is not available with the **Continuum Surface Stress** model.
- The **Continuum Surface Stress** model and the **Jump Adhesion** option are not available with the **Level Set** option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.3.8.4. Discretizing Using the Phase Localized Compressive Scheme

Most of the interface capturing or tracking schemes, which are common in literature, can simulate either diffused interface modeling *or* sharp interface modeling. There are a number of applications where you may be interested in modeling diffused *and* sharp interfaces in different regimes, which results in the need for a unique discretization procedure to handle such applications.

Below are some examples of such applications:

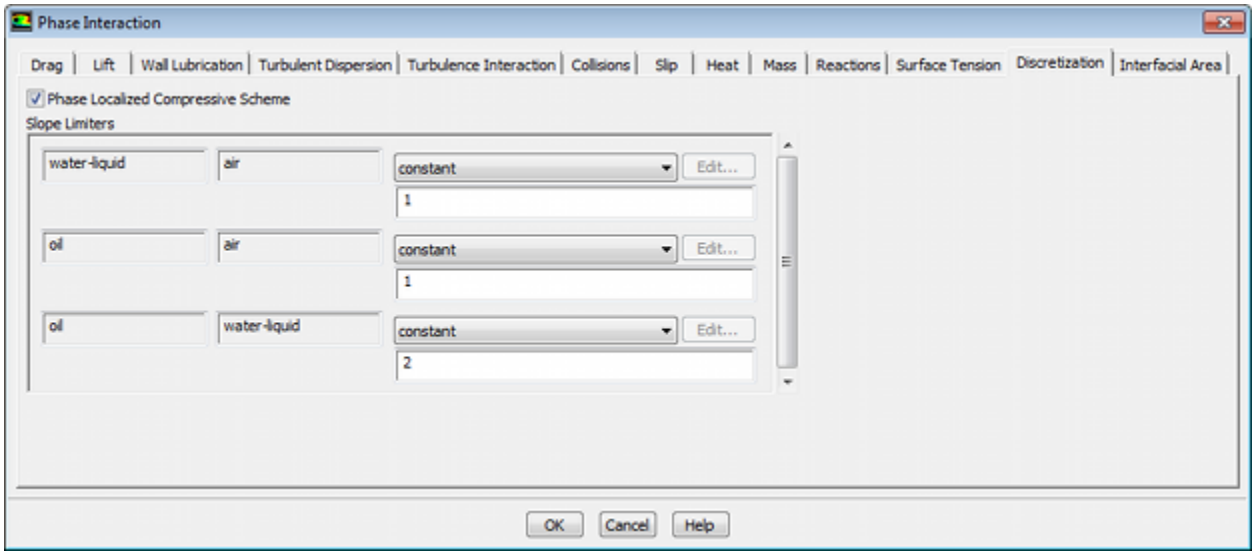
- **Air bubble rise in water-solid slurry:** Diffused interface modeling is required for the water and solid, and sharp interface modeling for the air bubble is desirable. A sharpening scheme would cause undesirable effects for the modeling of the diffused interface between water and solids and a diffusive scheme would not be able to maintain the sharp interface for bubble rising in the slurry.
- **Evaporation/condensation in a tank partially filled with water and being heated at the bottom:** Diffused interface modeling is required for the liquid-vapor and sharp interface modeling for the water-air regime is desirable. A sharpening scheme, would not be able to simulate the diffused phenomena of evaporation/condensation for the liquid- vapor phase and a diffusive scheme would not be able to maintain the sharp interface between water and air.
- **Air jet penetrating through layer of liquids:** You may be interested in diffused jet modeling and sharp interface modeling between the liquid layers. A sharpening scheme would not be able to maintain the continuous air stream and a diffusive scheme would not be able to maintain the sharp interfaces between the layers of liquids.

Using the Modified HRIC and Compressive schemes for such applications would result in the HRIC scheme producing undesirable sharpening of the dispersed phases and undesirable diffusion of the continuous phases, whereas the Compressive scheme would produce undesirable sharpening of the dispersed phases.

Therefore, the phase localized compressive scheme is particularly useful in cases where the desirable behavior is such that you have diffused modeling of dispersed phases and sharp modeling of continuous phases. In ANSYS Fluent, diffusive and anti-diffusive discretization procedures can be used across the distinct interfaces, which share a pair of phases. This functionality is provided through the compressive discretization scheme, where the degree of diffusion or sharpness is controlled through the value of the slope limiters. The theory used is described in The Compressive Scheme and Interface-Model-based Variants.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.32: The Phase Interaction Dialog Box for the VOF Model (Discretization Tab)



To use the phase localized compressive scheme, perform the following steps:

1. Click the **Discretization** tab.

   Note

   The **Discretization** tab is available if the VOF model or the Eulerian multiphase model with **Mulit-Fluid VOF** is enabled, and the **Phase Localized Discretization** option is enabled in the **Interface Modeling Options** dialog box. (Interface Modeling Type (p. 1371)).

2. Enable **Phase Localized Compressive Scheme**.

   Important

   When this option is enabled, the **Compressive** spatial discretization scheme is automatically selected for the **Volume Fraction** in the **Solution Methods** dialog box.

3. For each pair of phases, specify the value of the slope limiter. You can enter a value of 0, 1, or 2, or any value between 0 and 2. Refer to Table 24.11: Slope Limiter Discretization Scheme (p. 1444) to equate each value of the slope limiter with a discretization scheme.

   Table 24.11: Slope Limiter Discretization Scheme

Slope Limiter Value β	Scheme
0	first order upwind
1	second order reconstruction bounded by the global minimum/maximum of the volume fraction
2	compressive

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Slope Limiter Value β	Scheme
$0<\beta<1$ and $1<\beta<2$	blended: where a value between 0 and 1 means blending of the first order and second order and a value between 1 and 2 means blending of the second order and compressive scheme

When using the **Phase Localized Compressive Scheme**, note the following:

- The minimum limit for the slope limiter is 0, whereas the maximum is 2.
- The slope limiter can be interpreted as the degree of compression/anti-diffusion, where 0 demonstrates the minimum compression and 2 demonstrates the maximum compression.
- For interfaces sharing the diffused phases, a slope limiter value of 2 should not be used. A value between 0 and 1 is recommended.
- For interfaces sharing the continuous phases, any value between 0 and 2 can be used depending on the application.
- For interfaces sharing the continuous and diffused phases, any value between 0 and 2 can be used based on the application.
- If you want variable discretization behavior for an interface between two phases, you can do so via the `DEFINE_PROPERTY` user-defined function.

Note

– If the interface has a transition from sharp to diffused modeling, you should not experience any problems.

– If the interface has a transition from diffused to sharp modeling, this transition should be smooth by gradually varying the value of the slope limiter within some transition zone.

24.3.9. Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation

If you are using the **Explicit** volume fraction formulation in ANSYS Fluent, an explicit solution for the volume fraction is obtained either once each time step or once each iteration, depending upon your inputs to the model. You also have control over the time step used for the volume fraction calculation.

You can access the controls for the volume fraction from the Multiphase Model Dialog Box (p. 2171) by clicking **Expert Options...**

There are two inputs for the time-dependent calculation for the VOF model:

Sub-Time Step Calculation Method

When ANSYS Fluent uses the **Explicit** formulation, the time step used for the volume fraction calculation will not be the same as the time step used for the rest of the transport equations. ANSYS Fluent will refine the time step for VOF automatically, based on your input for the maximum **Courant Number** allowed near the free surface. The Courant number is a dimensionless number that compares the time step in a calculation to the characteristic time of transit of a fluid element across a control volume.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The characteristic transit time for a fluid element across the control volume represents the time taken by the fluid to empty out of the cell. This transit time is taken as the smallest of such time in the region near the fluid interface. A sub time step, for use in the VOF calculations, is computed based on this characteristic time, and the maximum allowed **Courant Number** set in the Multiphase Model Dialog Box (p. 2171). For example, if the maximum allowable **Courant Number** is `0.25` (default), the computed sub time step will have a maximum value equal to a quarter of the minimum transit time for any cell near the interface.

In Fluent, the sub time step size for VOF calculations can be computed using the following options:

- **Velocity Based:** The sub time step is estimated by the cell size and the fluid velocity normal to the interface:

$$\triangle t_v = C\frac{\triangle x}{v_{fluid}} \tag{24.7}$$

  where, C is the Courant Number, v_{fluid} is the fluid velocity, and $\triangle x$ is the cell size.

- **Flux Based**: For this option, the sub time step is estimated based on the cell volume and the summation of outgoing fluxes in the cell:

$$\triangle t_f = C\frac{V}{\sum_{cell} U_f} \tag{24.8}$$

  where, C is the Courant Number, V is the volume, and U_f are the outgoing fluxes.

- **Flux Averaged**: The sub time step size is estimated by volumetric averaging the calculations of the **Flux Based** method for the neighboring cells.

- **Hybrid**: This is the default method for calculating sub time step size. The sub time step size is estimated by blending the **Velocity Based** and **Flux Averaged** calculation methods.

Note

The **Flux Based** calculation method is the most conservative sub-time step size estimation, while the **Velocity Based** calculation is the most aggressive. **Flux Averaged** and **Hybrid** methods fall in between for most cases.

Aggressive sub time step calculation methods generally save time during interface reconstruction. However, the aggressive method can lead to increased number of iterations due to larger transient errors being introduced while integrating over the sub time steps for the interface reconstruction.

Solve VOF Every Iteration

By default, ANSYS Fluent will solve the volume fraction equation(s) once for each time step. This means that the convective flux coefficients appearing in the other transport equations will not be completely updated each iteration, since the volume fraction fields will not change from iteration to iteration.

When ANSYS Fluent solves these equations every iteration, the convective flux coefficients in the other transport equations will be updated based on the updated volume fractions at each iteration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This choice is the less stable of the two, and requires more computational effort per time step than the default choice.

Important

If you are using sliding meshes, or dynamic meshes with layering and/or remeshing, using the **Solve VOF Every Iteration** option will yield more accurate results, although at a greater computational cost.

24.3.10. Modeling Solidification/Melting

If you are including melting or solidification in your VOF calculation, note the following:

- It is possible to model melting or solidification in a single phase or in multiple phases.
- For phases that are *not* melting or solidifying, you must set the latent heat (L), liquidus temperature ($T_{liquidus}$), and solidus temperature ($T_{solidus}$) to zero.

See Modeling Solidification and Melting (p. 1527) for more information about melting and solidification.

24.4. Setting Up the Mixture Model

For background information about the mixture model and the limitations that apply, refer to Overview in the Theory Guide.

For additional information, see the following sections:
24.4.1. Defining the Phases for the Mixture Model
24.4.2. Including Mixture Drift Force
24.4.3. Including Cavitation Effects

24.4.1. Defining the Phases for the Mixture Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction for a mixture model calculation are provided below.

24.4.1.1. Defining the Primary Phase

The procedure for defining the primary phase in a mixture model calculation is the same as for a VOF calculation. See Defining the Primary Phase (p. 1436) for details.

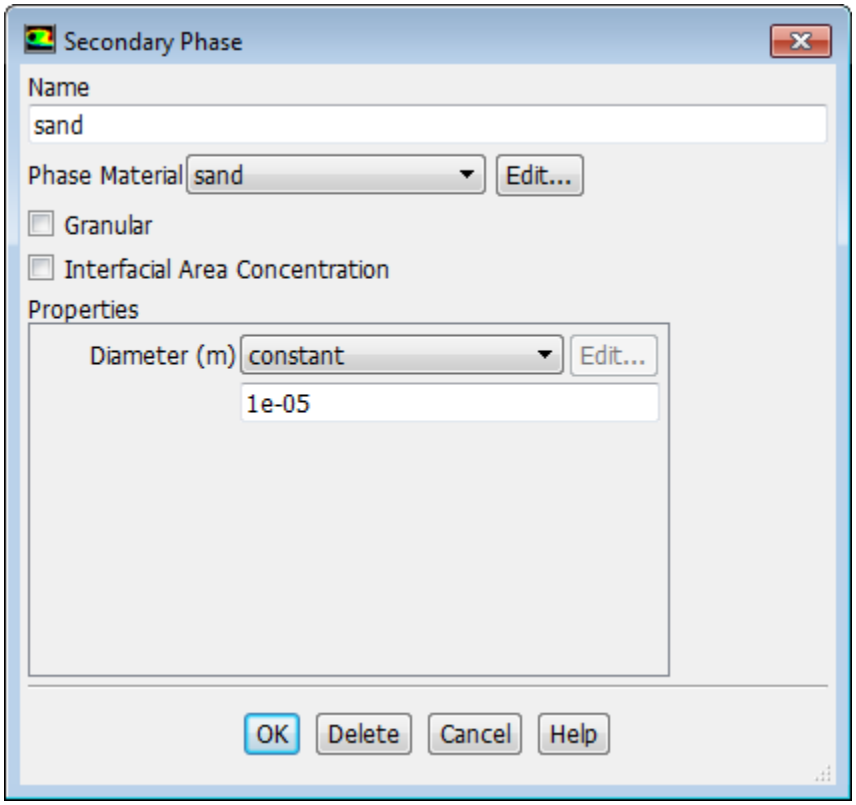
24.4.1.2. Defining a Non-Granular Secondary Phase

To define a non-granular (that is, liquid or vapor) secondary phase in a mixture multiphase calculation, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.33: The Secondary Phase Dialog Box for the Mixture Model (p. 1448)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.33: The Secondary Phase Dialog Box for the Mixture Model



3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see Defining the Primary Phase (p. 1436)). For a particulate phase (which must be placed in the fluid materials category, as mentioned in Steps for Using a Multiphase Model (p. 1365)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.

6. In the **Secondary Phase** dialog box, specify the **Diameter** of the bubbles, droplets, or particles of this phase (d_p in Equation 17.129 in the Theory Guide). You can specify a constant value, or use a user-defined function. See the Fluent Customization Manual for details about user-defined functions. Note that when you are using the mixture model without slip velocity, this input is not necessary, and it will not be available to you.

7. Click **OK** in the **Secondary Phase** dialog box.

24.4.1.3. Defining a Granular Secondary Phase

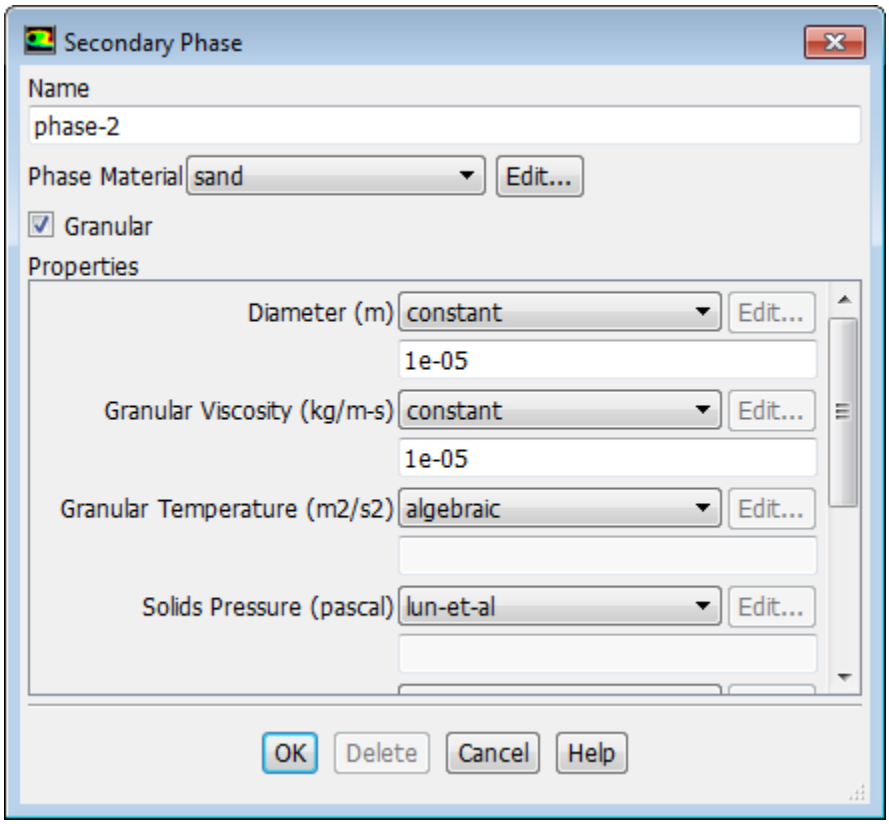
To define a granular (that is, particulate) secondary phase in a mixture model multiphase calculation, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.34: The Secondary Phase Dialog Box for a Granular Phase Using the Mixture Model (p. 1449)).

Figure 24.34: The Secondary Phase Dialog Box for a Granular Phase Using the Mixture Model



3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see Defining the Primary Phase (p. 1436)). For a granular phase (which must be placed in the fluid materials category, as mentioned in Steps for Using a Multiphase Model (p. 1365)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.

   Important

   Note that all properties for granular flows can be defined by user-defined functions (UDFs).

   See the Fluent Customization Manual for details about user-defined functions.

6. Enable the **Granular** option.

7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Diameter

specifies the diameter of the particles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

Granular Viscosity

specifies the method for computing the kinetic ($\mu_{s,kin}$) and collisional ($\mu_{s,col}$) components of the granular viscosity (Equation 17.137 in the *Fluent Theory Guide*). Selecting **constant**, **syamlal-obrien** (Equation 17.139 in the *Fluent Theory Guide*), or **gidaspow** (Equation 17.140 in the *Fluent Theory Guide*) will use these expressions for the kinetic portion of the viscosity and will calculate the collisional portion of the viscosity from Equation 17.138 in the *Fluent Theory Guide*. Alternatively, you can select **user-defined** to use a user-defined function. Note that if you select **user-defined**, your user-defined function must include both the kinetic portion and the collisional portion of the viscosity in the value it returns.

Frictional Pressure

specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johnson-et-al** to apply Equation 17.317 in the Theory Guide, **syamlal-obrien** to apply Equation 17.228 in the Theory Guide, **based-ktgf**, where the frictional pressure is defined by the kinetic theory [26] (p. 2888). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You must hook a user-defined function when selecting the **user-defined** option. See the Fluent Customization Manual for information on hooking a UDF.

Frictional Modulus

is defined as

$$G=\frac{\partial P_{friction}}{\partial \alpha_{friction}} \tag{24.9}$$

with $G \geq 0$, which is the **derived** option. You can also specify a **user-defined** function for the frictional modulus.

Friction Packing Limit

specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5. This is only a general rule of thumb as there may be other factors involved.

Granular Temperature

specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles. Choose either the **algebraic**, the **constant**, or **user-defined** option.

Solids Pressure

specifies the pressure gradient term, ∇p_s, in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, or the **user-defined** option.

Radial Distribution

specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastoopour**, or a **user-defined** option.

Elasticity Modulus

is defined as

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$G=\frac{\partial P_s}{\partial \alpha_s} \tag{24.10}$$

with $G \geq 0$.

Choose either the **derived** or **user-defined** options.

Packing Limit

specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres, the packing limit is about 0.63, which is the default value in ANSYS Fluent. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

8. Click **OK** in the **Secondary Phase** dialog box.

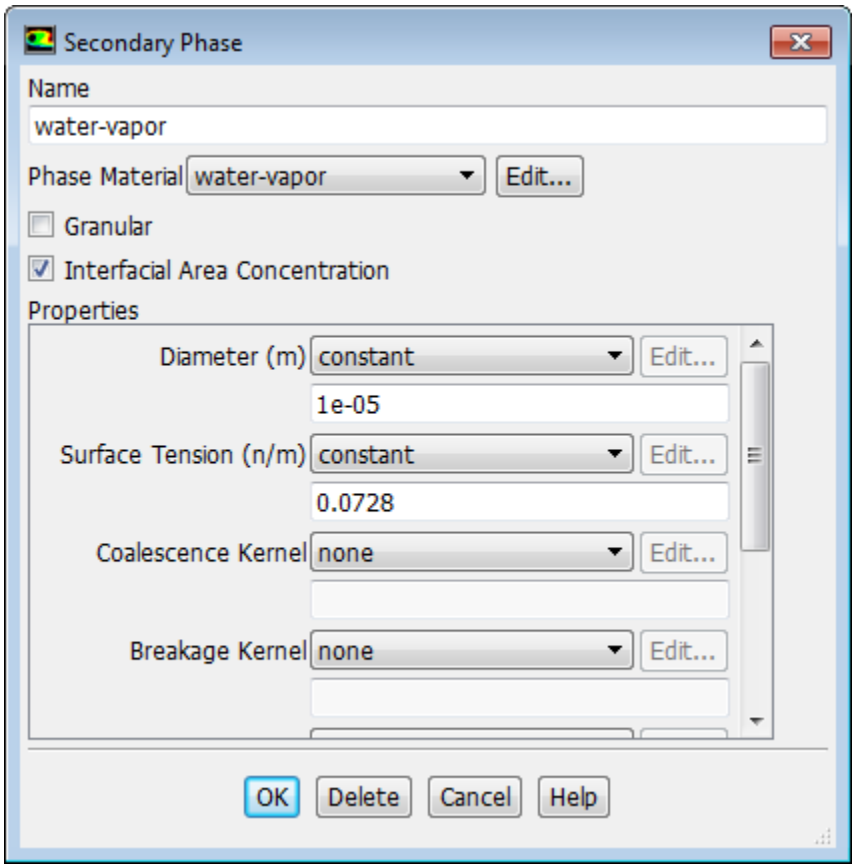
24.4.1.4. Defining the Interfacial Area Concentration

To solve the transport equation for interfacial area concentration of the secondary phase in the mixture model (Interfacial Area Concentration in the *Fluent Theory Guide*, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.

2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.35: The Secondary Phase Dialog Box Displaying the Interfacial Area Concentration Settings (p. 1451)).

Figure 24.35: The Secondary Phase Dialog Box Displaying the Interfacial Area Concentration Settings



3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**.

6. Enable the **Interfacial Area Concentration** option. Make sure the **Granular** option is disabled for the **Interfacial Area Concentration** option to be visible in the interface.

7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

   Diameter
   specifies the diameter of the particles or bubbles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the Fluent Customization Manual for details about user-defined functions. The **Diameter** recommended setting is **sauter-mean**, allowing for the effects of the interfacial area concentration values to be considered for mass, momentum and heat transfer across the interface between phases.

   Surface Tension
   specifies the surface tension at the liquid-air interface. You can select either the **hibiki-ishii** or the **ishii-kim** model.

   Coalescence Kernel and Breakage Kernel
   allows you to specify the coalescence and breakage kernels. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim** and **yao-morel** are described in detail in Interfacial Area Concentration in the Theory Guide.

   In addition to specifying the **hibiki-ishii**, **ishii-kim**, and **yao-morel** as the coalescence and breakage kernels, you can also tune the properties of the three models by using the `/define/phases/iac-expert/hibiki-ishii-model`, `/define/phases/iac-expert/ishii-kim-model`, and `/define/phases/iac-expert/yao-morel-model` text commands.

   For each of the three models you can specify the parameters listed in Table 24.12: Parameters for the Coalescence and Breakage Kernels (p. 1452)

   Table 24.12: Parameters for the Coalescence and Breakage Kernels

Hibiki-Ishii Model	Ishii-Kim Model	Yao-Morel Model
`Coefficient Gamma_c`	`Coefficient Crc`	`Coefficient K_c1`
`Coefficient K_c`	`Coefficient Cwe`	`Coefficient K_c3`
`Coefficient Gamma_b`	`Coefficient C`	`Coefficient K_b1`
`Coefficient K_b`	`Coefficient Cti`	`alpha_max`
`alpha_max`	`alpha_max`	

   These values are discussed in greater detail in Interfacial Area Concentration in the Theory Guide.

   Nucleation Rate
   is a source term for the interfacial area concentration that models the rate of formation of the dispersed phase. You can choose from **constant** or **user-defined**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Critical Weber Number
will need to be specified if you selected **ishii-kim** or **yao-morel** for the **Breakage Kernel**.

Dissipation Function
gives you the option to choose the formula which calculates the dissipation rate used in the **hibiki-ishii** and **ishii-kim** models. You can choose amongst **constant**, **wu-ishii-kim**, **fluent-ke**, and **user-defined** for the dissipation function.

The **wu-ishii-kim** option uses a simple algebraic correlation for ε:

$$\varepsilon = f_{TW}\left(1/\ 2D_h\right)v_m^3 \tag{24.11}$$

where

$$f_{TW} = \frac{0.316}{\left[(1-\alpha)Re_m\right]^{0.25}}$$

and

$$Re_m = \frac{\rho_m v_m D_h}{\mu_m}$$

where ρ_m, v_m, μ_m, and D_h are the mixture density, mixture velocity, mixture molecular viscosity, and hydraulic diameter of the flow path.

When you select the **wu-ishii-kim** model, you will set an additional input for **Hydraulic Diameter**.

Hydraulic Diameter
is the value used in Equation 24.11 (p. 1453), should you use the **wu-ishii-kim** formulation.

Min/Max Diameter
are the limits of the bubble diameters.

Note

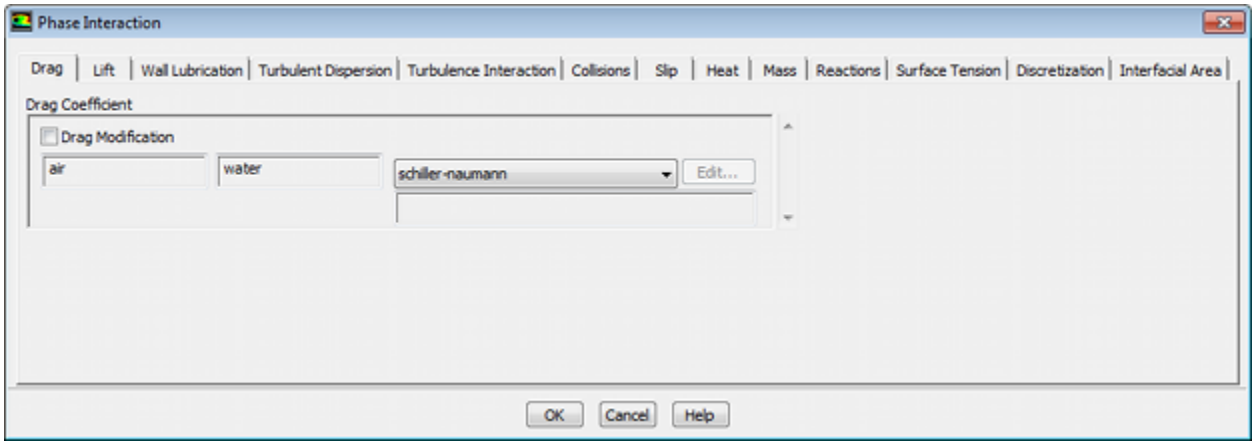
When solving a steady-state problem, the preferred setting for the **Under-Relaxation Factor** is 1.0, as the interfacial area equation for the boiling models is currently under-relaxed using a locally defined pseudo-time step. If you want extra explicit under-relaxation, you may set the value of the **Under-Relaxation Factor** to less than one, this may be done only in case of serious convergence problems with the interfacial area transport equation. To improve convergence you can switch to a pseudo-time step for the interfacial area concentration only, using the **define/phases/iac-expert/iac-pseudo-time-step** text command and set the local pseudo-time to less than 1.

24.4.1.5. Defining Drag Between Phases

For mixture multiphase flows with slip velocity, you can specify the drag function to be used in the calculation. The functions available here are a subset of those discussed in Defining the Phases for the Eulerian Model (p. 1456). See Relative (Slip) Velocity and the Drift Velocity in the Theory Guide for more information.

To specify drag laws, click **Interaction...** to open the Phase Interaction Dialog Box (p. 2363) (Figure 24.36: The Phase Interaction Dialog Box for the Mixture Model (Drag Tab) (p. 1454)), and then click the **Drag** tab.

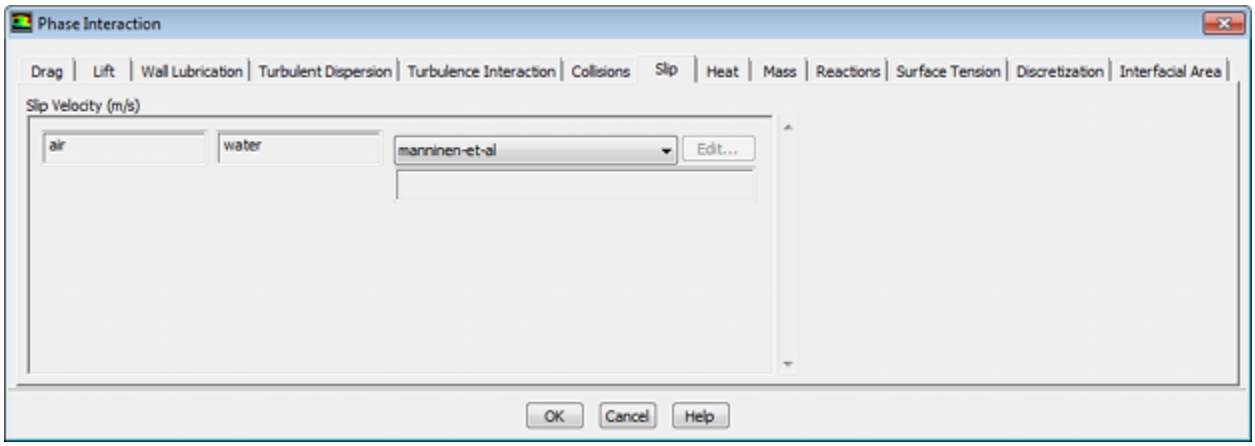
Figure 24.36: The Phase Interaction Dialog Box for the Mixture Model (Drag Tab)



24.4.1.6. Defining the Slip Velocity

If you are solving for slip velocities during the mixture calculation, and you want to modify the slip velocity definition, click **Interaction...** to open the Phase Interaction Dialog Box (p. 2363) (Figure 24.37: The Phase Interaction Dialog Box for the Mixture Model (**Slip** Tab) (p. 1454)), and then click the **Slip** tab.

Figure 24.37: The Phase Interaction Dialog Box for the Mixture Model (Slip Tab)



Under **Slip Velocity**, you can specify the slip velocity function for each secondary phase with respect to the primary phase by choosing the appropriate item in the adjacent drop-down list.

- Select **maninnen-et-al** (the default) to use the algebraic slip method of Manninen et al. [65] (p. 2890), described in Relative (Slip) Velocity and the Drift Velocity in the Theory Guide.
- Select **none** if the secondary phase has the same velocity as the primary phase (that is, no slip velocity).
- Select **user-defined** to use a user-defined function for the slip velocity. See the Fluent Customization Manual for details.

24.4.2. Including Mixture Drift Force

If you are solving for Slip Velocity and using one of the turbulence models in your Mixture multiphase calculation, you can also include the effects of the slip velocity on the momentum and turbulence equations. To include these effects, enable **Mixture Drift Force** in the Viscous Model Dialog Box (p. 2176). Note that the inclusion of these terms can slow down convergence noticeably. If you are looking for

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

additional accuracy, you may want to compute a solution first without these sources, and then continue the calculation with these terms included. In most cases these terms can be neglected.

24.4.3. Including Cavitation Effects

For mixture model calculations, it is possible to include the effects of cavitation, using ANSYS Fluent's cavitation models described in Cavitation Models in the Theory Guide.

To enable the Singhal et al. cavitation model, use the `solve/set/expert` text command and answer `yes` to `use Singhal-et-al cavitation model?`. The **Singhal-Et-Al Cavitation Model** option will now be visible in the **Phase Interaction** dialog box, under the **Mass** tab. Enable this option to include the Singhal et al. cavitation model.

You will specify three parameters to be used in the calculation of mass transfer due to cavitation. Set the **Vaporization Pressure**, the **Surface Tension Coefficient**, and the **Non-Condensable Gas Mass Fraction**. The default value of p_{sat} is 3540 Pa, the vaporization pressure for water at ambient temperature. Note that p_{sat} and the surface tension are properties of the liquid, depending mainly on temperature. **Non-Condensable Gas Mass Fraction** is the mass fraction of dissolved gases, which depends on the purity of the liquid.

When multiple species are included in one or more secondary phases, or the heat transfer due to phase change must be taken into account, the mass transfer mechanism must be defined *before* enabling the cavitation model. It may be noted, however, that for cavitation problems, at least *two* mass transfer mechanisms are defined:

- mass transfer from liquid to vapor.
- mass transfer from vapor to liquid.

To enable and set up the **Schnerr-Sauer** and **Zwart-Gerber-Belamri** cavitation models, refer to Including Mass Transfer Effects (p. 1383).

24.5. Setting Up the Eulerian Model

For background information about the Eulerian model and the limitations that apply, refer to Overview of the Eulerian Model in the Theory Guide.

For additional information, see the following sections:

24.5.1. Additional Guidelines for Eulerian Multiphase Simulations
24.5.2. Defining the Phases for the Eulerian Model
24.5.3. Modeling Turbulence
24.5.4. Including Heat Transfer Effects
24.5.5. Using an Algebraic Interfacial Area Model
24.5.6. Including the Dense Discrete Phase Model
24.5.7. Including the Boiling Model
24.5.8. Including the Multi-Fluid VOF Model

24.5.1. Additional Guidelines for Eulerian Multiphase Simulations

Once you have determined that the Eulerian multiphase model is appropriate for your problem (as described in Choosing a General Multiphase Model in the Theory Guide), you should consider the computational effort required to solve your multiphase problem. The required computational effort depends strongly on the number of transport equations being solved and the degree of coupling. For

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

the Eulerian multiphase model, which has a large number of highly coupled transport equations, computational expense will be high. Before setting up your problem, try to reduce the problem statement to the simplest form possible.

Instead of trying to solve your multiphase flow in all of its complexity on your first solution attempt, you can start with simple approximations and work your way up to the final form of the problem definition. Some suggestions for simplifying a multiphase flow problem are listed below:

- Use a hexahedral or quadrilateral mesh (instead of a tetrahedral or triangular mesh).
- Reduce the number of phases.

You may find that even a very simple approximation will provide you with useful information about your problem.

See Eulerian Model (p. 1516) and Setting Solution Limits (p. 1586) for more solution strategies for Eulerian multiphase calculations.

24.5.2. Defining the Phases for the Eulerian Model

Instructions for specifying the necessary information for the primary and secondary phases and their interaction for an Eulerian multiphase calculation are provided below.

24.5.2.1. Defining the Primary Phase

The procedure for defining the primary phase in an Eulerian multiphase calculation is the same as for a VOF calculation. See Defining the Primary Phase (p. 1436) for details.

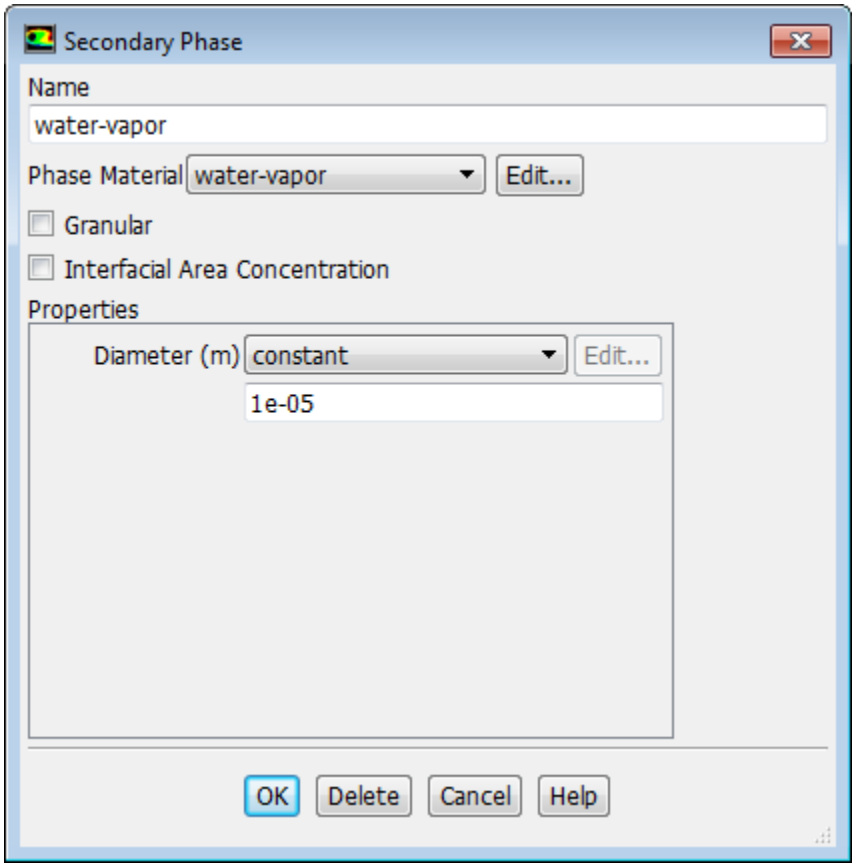
24.5.2.2. Defining a Non-Granular Secondary Phase

To define a non-granular (that is, liquid or vapor) secondary phase in an Eulerian multiphase calculation, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.
2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.38: The Secondary Phase Dialog Box for a Non-Granular Phase (p. 1457)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.38: The Secondary Phase Dialog Box for a Non-Granular Phase



3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see Defining the Primary Phase (p. 1436)).

6. In the **Secondary Phase** dialog box, specify the **Diameter** of the bubbles or droplets of this phase. You can specify a constant value, or use a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

7. Click **OK** in the **Secondary Phase** dialog box.

24.5.2.3. Defining a Granular Secondary Phase

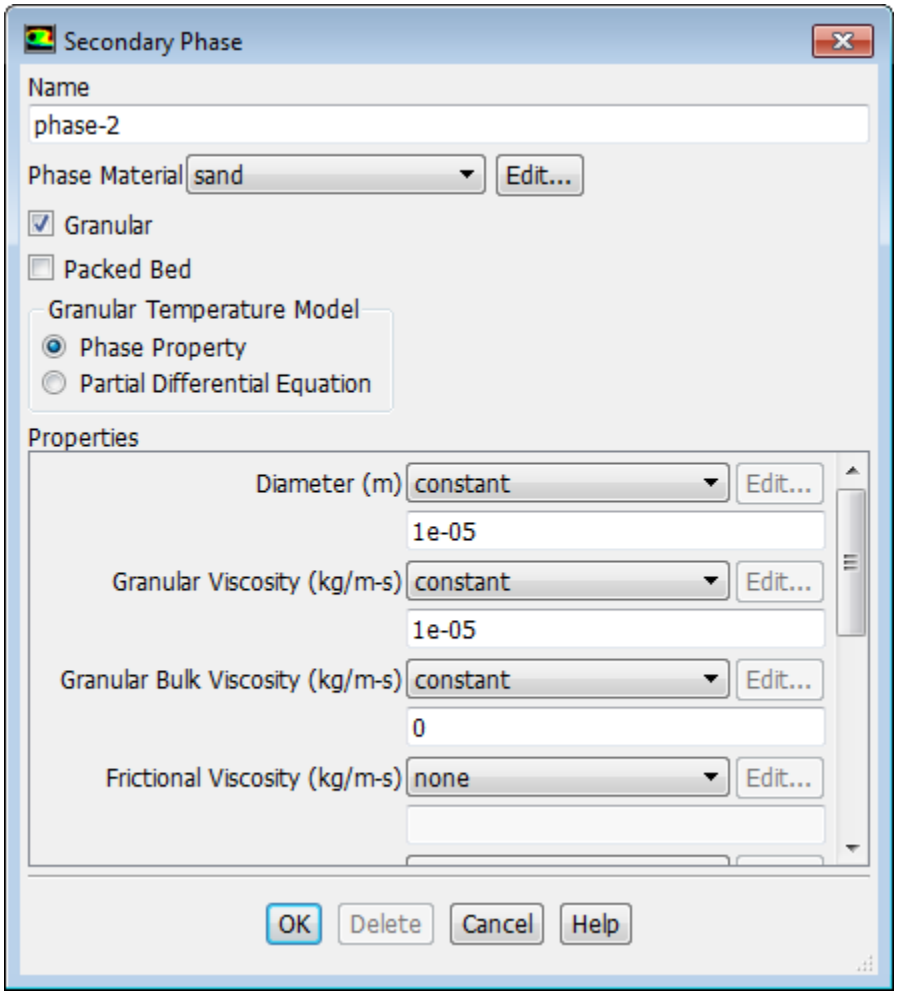
To define a granular (that is, particulate) secondary phase in an Eulerian multiphase calculation, perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.

2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.39: The Secondary Phase Dialog Box for a Granular Phase (p. 1458)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.39: The Secondary Phase Dialog Box for a Granular Phase



3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**, following the same procedure you used to set the material properties for the primary phase (see Defining the Primary Phase (p. 1436)). For a granular phase (which must be placed in the fluid materials category, as mentioned in Steps for Using a Multiphase Model (p. 1365)), you need to specify only the density; you can ignore the values for the other properties, since they will not be used.

   Important

   Note that all properties for granular flows can be defined by user-defined functions (UDFs).

   See the Fluent Customization Manual for details about user-defined functions.

6. Enable the **Granular** option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. (optional) Enable the **Packed Bed** option if you want to freeze the velocity field for the granular phase. Note that when you select the packed bed option for a phase, you should also use the fixed velocity option with a value of zero for all velocity components for all interior cell zones for that phase. Using fixed velocity in radial direction as a constant value (other than zero) does not ensure continuity. With the fixed velocity option, both velocity and pressure are fixed in a zone. Since face area in the radial direction is a function of radial distance from the axis, it will result in a mass conservation problem due to flux imbalance.

   Using zero fixed velocity in the radial direction does not cause any problems related to mass conservation.

8. Specify the **Granular Temperature Model**. Choose either the default **Phase Property** option or the **Partial Differential Equation** option. See Granular Temperature in the Theory Guide for details.

9. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

   Diameter

   specifies the diameter of the particles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the Fluent Customization Manual for details about user-defined functions.

   Granular Viscosity

   specifies the method for computing the kinetic ($\mu_{s,kin}$) and collisional ($\mu_{s,col}$) components of the granular viscosity (Equation 17.307 in the *Fluent Theory Guide*). Selecting **constant**, **syamlal-obrien** (Equation 17.309), or **gidaspow** (Equation 17.310) will use these expressions for the kinetic portion of the viscosity and will calculate the collisional portion of the viscosity from Equation 17.308 in the *Fluent Theory Guide*. Alternatively, you can select **user-defined** to use a user-defined function. Note that if you select **user-defined**, your user-defined function must include both the kinetic portion and the collisional portion of the viscosity in the value it returns.

   Granular Bulk Viscosity

   specifies the solids bulk viscosity (λ_q in Equation 17.169 in the Theory Guide). You can select **constant** (the default) in the drop-down list and specify a constant value, select **lun-et-al** to compute the value using Equation 17.311 in the Theory Guide, or select **user-defined** to use a user-defined function.

   Frictional Viscosity

   specifies a shear viscosity based on the viscous-plastic flow ($\mu_{s,fr}$ in Equation 17.307 in the Theory Guide). By default, the frictional viscosity is neglected, as indicated by the default selection of **none** in the drop-down list. If you want to include the frictional viscosity, you can select **constant** and specify a constant value, select **schaeffer** to compute the value using Equation 17.312 in the Theory Guide, select **johnson-et-al** to compute the value using Equation 17.317 in the Theory Guide, or select **user-defined** to use a user-defined function.

   Angle of Internal Friction

   specifies a constant value for the angle ϕ used in Schaeffer's expression for frictional viscosity (Equation 17.312 in the Theory Guide). This parameter is relevant only if you have selected **schaeffer** or **user-defined** for the **Frictional Viscosity**.

   Frictional Pressure

   specifies the pressure gradient term, $\nabla P_{friction}$, in the granular-phase momentum equation. Choose **none** to exclude frictional pressure from your calculation, **johnson-et-al** to apply Equation 17.317 in the Theory Guide, **syamlal-obrien** to apply Equation 17.228 in the Theory Guide, **based-ktgf**, where the frictional pressure is defined by the kinetic theory [26] (p. 2888). The solids pressure tends to a large value near the packing limit, depending on the model selected for the radial distribution function. You

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

must hook a user-defined function when selecting the **user-defined** option. See the Fluent Customization Manual for information on hooking a UDF.

Frictional Modulus

is defined as

$$G=\frac{\partial P_{friction}}{\partial \alpha_{friction}} \tag{24.12}$$

with $G \geq 0$, which is the **derived** option. You can also specify a **user-defined** function for the frictional modulus.

Friction Packing Limit

specifies a threshold volume fraction at which the frictional regime becomes dominant. It is assumed that for a maximum packing limit of 0.6, the frictional regime starts at a volume fraction of about 0.5. This is only a general rule of thumb as there may be other factors involved.

Granular Conductivity

specifies the solids granular conductivity (k_{Θ_s} in Equation 17.321 in the Theory Guide). You can select **syamlal-obrien** to compute the value using Equation 17.322 in the Theory Guide, select **gidaspow** to compute the value using Equation 17.323 in the Theory Guide, or select **user-defined** to use a user-defined function. Note that in the algebraic model, shown in Figure 24.39: The Secondary Phase Dialog Box for a Granular Phase (p. 1458), the granular conductivity is not required in the computation of the granular temperature. This has been obtained by neglecting convection and diffusion in the transport equation, Equation 17.321 in the Theory Guide [116] (p. 2893).

Granular Temperature

specifies temperature for the solids phase and is proportional to the kinetic energy of the random motion of the particles. Choose the **algebraic**, **constant**, **dpm-averaged**, or **user-defined** option.

Note

The **dpm-averaged** method is only available when using the Dense Discrete Phase Model (DDPM).

Solids Pressure

specifies the pressure gradient term, ∇p_s, in the granular-phase momentum equation. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, **none**, or a **user-defined** option.

Radial Distribution

specifies a correction factor that modifies the probability of collisions between grains when the solid granular phase becomes dense. Choose either the **lun-et-al**, the **syamlal-obrien**, the **ma-ahmadi**, the **arastoopour**, or a **user-defined** option.

Elasticity Modulus

is defined as

$$G=\frac{\partial P_s}{\partial \alpha_s} \tag{24.13}$$

with $G \geq 0$.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Packing Limit

specifies the maximum volume fraction for the granular phase ($\alpha_{s,max}$). For monodispersed spheres, the packing limit is about 0.63, which is the default value in ANSYS Fluent. In polydispersed cases, however, smaller spheres can fill the small gaps between larger spheres, so you may need to increase the maximum packing limit.

10. Click **OK** in the **Secondary Phase** dialog box.

24.5.2.4. Defining the Interfacial Area Concentration

When using the Eulerian multiphase model, you can choose to solve a transport equation for the interfacial area, which allows for a distribution of secondary phase diameter, or you can use an algebraic model to compute the interfacial area from a specified diameter. To use an algebraic model, refer to Using an Algebraic Interfacial Area Model (p. 1480). To solve the transport equation (Interfacial Area Concentration in the *Fluent Theory Guide*), perform the following steps:

1. Select the phase (for example, **phase-2**) in the **Phases** list.

2. Click **Edit...** to open the Secondary Phase Dialog Box (p. 2357) (Figure 24.35: The Secondary Phase Dialog Box Displaying the Interfacial Area Concentration Settings (p. 1451)).

3. In the **Secondary Phase** dialog box, enter a **Name** for the phase.

4. Specify which material the phase contains by choosing the appropriate material in the **Phase Material** drop-down list.

5. Define the material properties for the **Phase Material**.

6. Enable the **Interfacial Area Concentration** option. Make sure the **Granular** option is disabled for the **Interfacial Area Concentration** option to be visible in the interface.

7. In the **Secondary Phase** dialog box, specify the following properties of the particles of this phase:

   Diameter

   specifies the diameter of the particles or bubbles. You can select **constant** in the drop-down list and specify a constant value, or select **user-defined** to use a user-defined function. See the Fluent Customization Manual for details about user-defined functions. The **Diameter** recommended setting is **sauter-mean**, allowing for the effects of the interfacial area concentration values to be considered for mass, momentum and heat transfer across the interface between phases.

   Coalescence Kernel and Breakage Kernel

   allows you to specify the coalescence and breakage kernels. You can select **none**, **constant**, **hibiki-ishii**, **ishii-kim**, **yao-morel**, or **user-defined**. The three options, **hibiki-ishii**, **ishii-kim** and **yao-morel** are described in detail in Interfacial Area Concentration in the Theory Guide.

   In addition to specifying the **hibiki-ishii**, **ishii-kim**, and **yao-morel** as the coalescence and breakage kernels, you can also tune the properties of the three models by using the `/define/phases/iac-expert/hibiki-ishii-model`, `/define/phases/iac-expert/ishii-kim-model`, and `/define/phases/iac-expert/yao-morel-model` text commands.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For each of the three models you can specify the parameters listed in Table 24.13: Parameters for the Coalescence and Breakage Kernels (p. 1462)

Table 24.13: Parameters for the Coalescence and Breakage Kernels

Hibiki-Ishii Model	Ishii-Kim Model	Yao-Morel Model
Coefficient Gamma_c	Coefficient Crc	Coefficient K_c1
Coefficient K_c	Coefficient Cwe	Coefficient K_c3
Coefficient Gamma_b	Coefficient C	Coefficient K_b1
Coefficient K_b	Coefficient Cti	alpha_max
alpha_max	alpha_max	

These values are discussed in greater detail in Interfacial Area Concentration in the Theory Guide.

Nucleation Rate

is a source term for the interfacial area concentration that models the rate of formation of the dispersed phase. You can choose from **constant** or **user-defined**. If the **Boiling Model** option is enabled, you can also select **yao-morel**. The **yao-morel** option is described in Yao-Morel Model in the Theory Guide.

Critical Weber Number

will need to be specified if you selected **ishii-kim** or **yao-morel** for the **Breakage Kernel**.

Dissipation Function

gives you the option to choose the formula which calculates the dissipation rate used in the **hibiki-ishii** and **ishii-kim** models. You can choose amongst **constant**, **wu-ishii-kim**, **fluent-ke**, and **user-defined** for the dissipation function.

The **wu-ishii-kim** option uses a simple algebraic correlation for ε:

$$\varepsilon = f_{TW}\left(1/\ 2D_h\right)v_m^3 \tag{24.14}$$

where

$$f_{TW} = \frac{0.316}{\left[(1-\alpha)Re_m\right]^{0.25}}$$

and

$$Re_m = \frac{\rho_m v_m D_h}{\mu_m}$$

where ρ_m, v_m, μ_m, and D_h are the mixture density, mixture velocity, mixture molecular viscosity, and hydraulic diameter of the flow path.

When you select the **wu-ishii-kim** model, you will set an additional input for **Hydraulic Diameter**.

Hydraulic Diameter

is the value used in Equation 24.14 (p. 1462), should you use the **wu-ishii-kim** formulation.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Min/Max Diameter
allow you to specify the minimum and maximum diameters of the secondary phase to which the interfacial area concentration model is applied, preventing some computing anomalies to spread beyond control.

Note

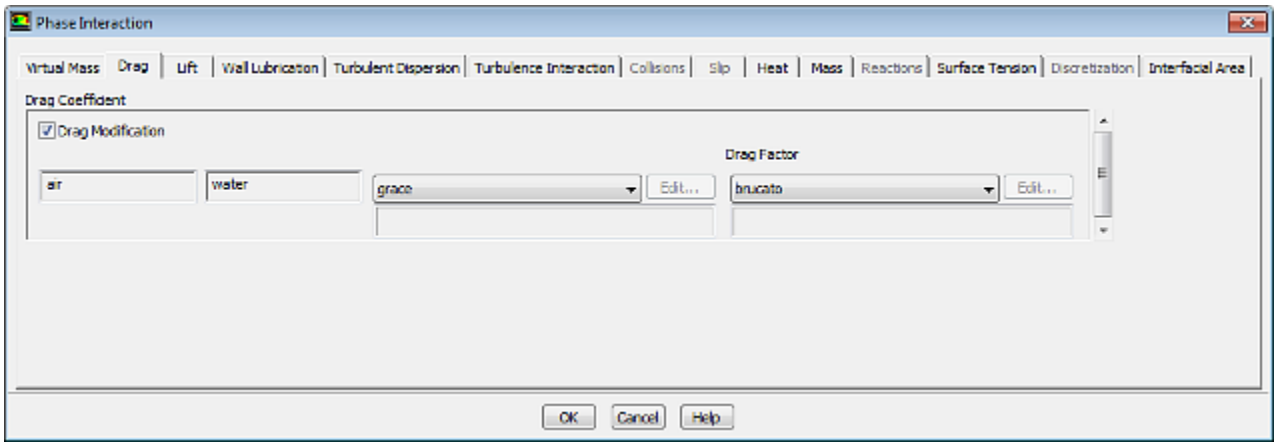
When solving a steady-state problem, the preferred setting for the **Under-Relaxation Factor** is 1.0, as the interfacial area equation for the boiling models is currently under-relaxed using a locally defined pseudo-time step. If you want extra explicit under-relaxation, you may set the value of the **Under-Relaxation Factor** to less than one, this may be done only in case of serious convergence problems with the interfacial area transport equation. To improve convergence you can switch to a pseudo-time step for the interfacial area concentration only, using the **define/phases/iac-expert/iac-pseudo-time-step** text command and set the local pseudo-time to less than 1.

24.5.2.5. Defining the Interaction Between Phases

For both granular and non-granular flows, you will need to specify the drag function to be used in the calculation of the momentum exchange coefficients. You can also specify lift forces, wall lubrication forces (for non-granular flows only), turbulent dispersion forces, surface tension effects, and virtual mass force. For granular flows, you will also need to specify the restitution coefficient(s) for particle collisions.

To specify these parameters, click **Interaction...** to open the Phase Interaction Dialog Box (p. 2363) and visit the **Drag**, **Lift**, **Wall Lubrication**, **Turbulent Dispersion**, **Collisions**, and **Surface Tension** tabs.

Setup → Models → Multiphase → Phases → Edit... → Interaction...



24.5.2.5.1. Specifying the Drag Function

ANSYS Fluent allows you to specify a drag function for each pair of phases. Perform the following steps:

1. Click the **Drag** tab.

2. For each pair of phases, select the appropriate drag function from the corresponding drop-down list.

   - Select **ishii** to use the fluid-fluid drag function described by Equation 17.419 in the Theory Guide. This option is available when the boiling model is enabled.

- Select **schiller-naumann** to use the fluid-fluid drag function described by Equation 17.182 in the Theory Guide. The Schiller and Naumann model is the default method, and it is acceptable for general use in all fluid-fluid multiphase calculations. When using the homogeneous population balance models you can also select **schiller-naumann-pb** in which case the interfacial area will be calculated directly from the population balance variables.

- Select **morsi-alexander** to use the fluid-fluid drag function described by Equation 17.186 in the Theory Guide. The Morsi and Alexander model is the most complete, adjusting the function definition frequently over a large range of Reynolds numbers, but calculations with this model may be less stable than with the other models.

- Select **symmetric** to use the fluid-fluid drag function described by Equation 17.192 in the Theory Guide. The symmetric model is recommended for flows in which the secondary (dispersed) phase in one region of the domain becomes the primary (continuous) phase in another. For example, if air is injected into the bottom of a container filled halfway with water, the air is the dispersed phase in the bottom half of the container; in the top half of the container, the air is the continuous phase. The **symmetric** drag law is the default method for the **Multi-Fluid VOF Model**, which is available with Eulerian multiphase model.

- Select **grace** to use the fluid-fluid drag function described by Equation 17.197 in the Theory Guide. The Grace model is recommended for gas-liquid flows in which the bubbles can have a range of shapes such as spherical, elliptical, or cap.

- Select **tomiyama** to use the fluid-fluid drag function described by Equation 17.203 in the Theory Guide. Like the Grace model, the Tomiyama model is recommended for gas-liquid flows in which the bubbles can have a range of shapes such as spherical, elliptical, or cap.

- Select **anisotropic** to use the fluid-fluid drag function described in Multi-Fluid VOF Model in the Theory Guide. The **anisotropic** drag law is recommended for free surface modeling. It is based on higher drag in the normal direction to the interface and lower drag in the tangential direction to the interface.

- Select **universal-drag** for bubble-liquid and/or droplet-gas flow when the characteristic length of the flow domain is much greater than the averaged size of the droplets/bubbles. It is suitable for flows in which the bubbles/droplets may have a range of shapes. The universal drag law is described using Equation 17.207 in the Theory Guide. When **universal-drag** is selected, you will need to set a value for the surface tension coefficient, under the **Surface Tension** tab, in the **Phase Interaction** dialog box. This value will apply to the primary phase and the secondary phase.

- Select **wen-yu** to use the fluid-solid drag function described by Equation 17.242 in the Theory Guide. The Wen and Yu model is applicable for dilute phase flows, in which the total secondary phase volume fraction is significantly lower than that of the primary phase. When using the homogeneous population balance models you can also select **wen-yu-pb** in which case the interfacial area will be calculated directly from the population balance variables.

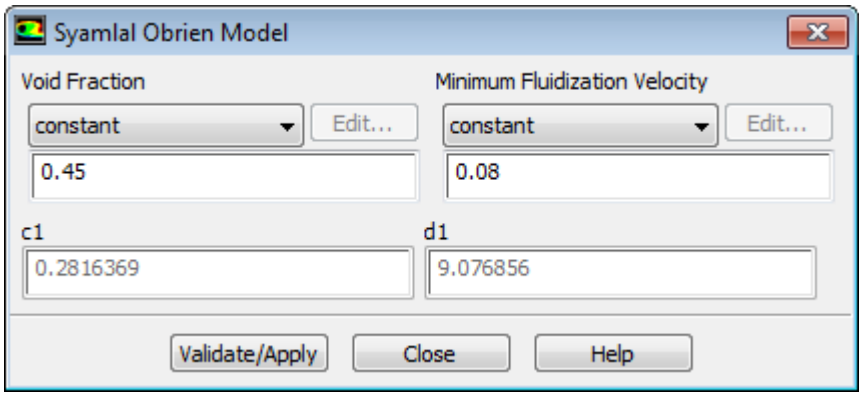
- Select **gidaspow** to use the fluid-solid drag function described by Equation 17.244 in the Theory Guide. The Gidaspow model is recommended for dense fluidized beds.

- Select **syamlal-obrien** to use the fluid-solid drag function described by Equation 17.229 in the Theory Guide. The Syamlal-O'Brien model is recommended for use in conjunction with the Syamlal-O'Brien model for granular viscosity.

- Select **syamlal-obrien-para** to use the parameterized formulation of the Syamlal-O'Brien model described by Equation 17.239 in the Theory Guide. This model addresses under/over-prediction of bed expansion

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

that can arise with **syamlal-obrien**. When you first select this model, you will be presented with the **Syamlal Obrien Model** dialog box.



There are two inputs:

Void Fraction
the volume fraction of the gas phase in the bed at the minimum fluidization condition

Minimum Fluidization Velocity
the expected or experimentally-determined nominal minimum fluidization velocity of the gas phase

Once you have input these values, click **Validate/Apply** to compute the coefficients **c1** and **d1** used in Equation 17.240 in the *Fluent Theory Guide*. A message will also be printed to the text user interface summarizing the fluid and flow properties used in the computation and the resulting values. You should check that these property values are consistent with the properties set elsewhere.

Important

If you change property values in the **Create/Edit Materials** dialog box or diameter in the **Secondary Phase** dialog box, you must initialize the flow field or run at least one iteration before computing c1 and d1. Otherwise, incorrect properties will be used in the computation.

Note that the **syamlal-obrien-para** model is appropriate only for Geldart Group B particles and is only applicable to cases involving a single secondary phase.

- Select **syamlal-obrien-symmetric** to use the solid-solid drag function described by Equation 17.250 in the Theory Guide. The symmetric Syamlal-O'Brien model is appropriate for a pair of solid phases.
- Select **huilin-gidaspow** to use the fluid-solid drag function described by Equation 17.246 in the Theory Guide. This option provides a better blending function for the Gidaspow model when moving from the dense packing limit to the dilute flow limit.
- Select **gibilaro** to use the fluid-solid drag function described by Equation 17.248 in the Theory Guide. This option is used for circulating fluidized beds
- Select **constant** to specify a constant value for the drag function, and then specify the value in the text field.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **user-defined** to use a user-defined function for the drag function (see the Fluent Customization Manual for details).
- If you want to temporarily ignore the interaction between two phases, select **none**.

24.5.2.5.1.1. Drag Modification

When using the Eulerian or Mixture multiphase models, you can optionally specify a drag modification term for the selected drag law. The drag modification term acts as a multiplier for the drag coefficient computed from the models detailed in Specifying the Drag Function (p. 1463). You can specify the drag modification term individually for each pair of primary-secondary phases. To enable drag modification, perform the following steps:

1. Check **Drag Modification** in the **Drag** tab of the **Phase Interaction** dialog box.

   *An additional drop-down list will appear under **Drag Factor** for each primary-secondary phase pair.*

2. For each pair of phases, select the **Drag Factor** to use from the drop-down list.
   - Select **none** to use the selected drag model without modification.
   - Select **constant** to specify a constant value for the drag modification factor.
   - Select **brucato** to use the Brucato et al. correlation described by Brucato et al. Correlation in the Theory Guide.
   - Select **user-defined** to use a user-defined function for the drag modification factor (see `DEFINE_EXCHANGE_PROPERTY` in the Fluent Customization Manual for details).

For additional details on the implementation of the drag modification, see Drag Modification in the Theory Guide.

24.5.2.5.2. Specifying the Restitution Coefficients (Granular Flow Only)

For granular flows, you need to specify the coefficients of restitution for collisions between particles (e_{ls} in Equation 17.250 and e_{ss} in Equation 17.290 in the Theory Guide). In addition to specifying the restitution coefficient for collisions between each pair of granular phases, you will also specify the restitution coefficient for collisions between particles of the same phase.

Perform the following steps:

1. Click the **Collisions** tab to display the **Restitution Coefficient** inputs.
2. For each pair of phases, specify a constant restitution coefficient. All restitution coefficients are equal to 0.9 by default.

24.5.2.5.3. Including the Lift Force

For both granular and non-granular flows, it is possible to include the effect of lift forces ($\vec{F}_{lift}$ in Equation 17.255 in the Theory Guide) on the secondary phase particles, droplets, or bubbles. These lift forces act on a particle, droplet, or bubble mainly due to velocity gradients in the primary-phase flow field. In most cases, the lift force is insignificant compared to the drag force, so there is no reason to

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

include it. If the lift force is significant (for example, if the phases separate quickly), you may want to include this effect.

Important

Note that the lift force will be more significant for larger particles, but the ANSYS Fluent model assumes that the particle diameter is much smaller than the interparticle spacing. Therefore, the inclusion of lift forces is not appropriate for closely packed particles or for very small particles.

To include the effect of lift forces, perform the following steps:

1. Click the **Lift** tab to display the **Lift Coefficient** inputs.

2. For each pair of phases, select the appropriate specification method from the corresponding drop-down list. Note that, since the lift forces for a particle, droplet, or bubble are due mainly to velocity gradients in the primary-phase flow field, you will not specify lift coefficients for pairs consisting of two secondary phases; lift coefficients are specified only for pairs consisting of a secondary phase and the primary phase.

   - Select **none** (the default) to ignore the effect of lift forces.
   - Select **constant** to specify a constant lift coefficient, and then specify the value in the text field.
   - Select **moraga** to use the Moraga lift model (Moraga Lift Force Model in the Theory Guide). The Moraga lift model is applicable to spherical solid particles, drops, and bubbles.
   - Select **saffman-mei** to use the Saffman-Mei lift model (Saffman-Mei Lift Force Model in the Theory Guide). The Saffman-Mei lift model is applicable to spherical solid particles, and to drops and bubbles that are not significantly distorted.
   - Select **legendre-magnaudet** to use the Legendre—Magnaudet lift model (Legendre-Magnaudet Lift Force Model in the Theory Guide). The Legendre-Magnaudet model is applicable to small diameter spherical fluid particles, though it can be applied to non-distorted liquid drops and bubbles. It accounts for momentum transfer between the flow around the particle and the inner recirculation flow inside the fluid particle caused by fluid friction/stresses at the fluid interface.
   - Select **tomiyama** to use the Tomiyama lift model (Tomiyama Lift Force Model in the Theory Guide). The Tomiyama model is applicable to larger-scale deformable bubbles in the ellipsoidal and spherical cap regimes. Its main feature is the prediction of the cross-over point in bubble size at which particle distortion causes a reversal in the sign of the lift force.
   - Select **user-defined** to use a user-defined function for the lift coefficient (see the Fluent Customization Manual for details).

24.5.2.5.4. Including the Wall Lubrication Force

For liquid-gas bubbly flows using the Eulerian multiphase model, you can include the effect of wall lubrication forces ($\vec{F}_{wl}$ in Equation 17.168 in the Theory Guide) on the secondary phase bubbles. These forces tend to push the bubbles away from walls at small wall distances. For details on how wall lubrication is modeled in ANSYS Fluent see Wall Lubrication Force in the Theory Guide.

To include the effect of wall lubrication forces, perform the following steps:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Click the **Wall Lubrication** tab to display the **Wall Lubrication** inputs.

2. For each pair of phases, select the appropriate specification method from the corresponding drop-down list. Note that you will specify the wall lubrication only for pairs consisting of a secondary phase and the primary phase.

   - Select **none** (the default) to ignore the effect of wall lubrication forces.

   - Select **antal-et-al** to use the Antal et al. model (Antal et al. Model in the Theory Guide). You can edit the model parameters in the **Antal Model** dialog box (Figure 24.40: Antal et al. Model Dialog Box (p. 1468)).

     Figure 24.40: Antal et al. Model Dialog Box

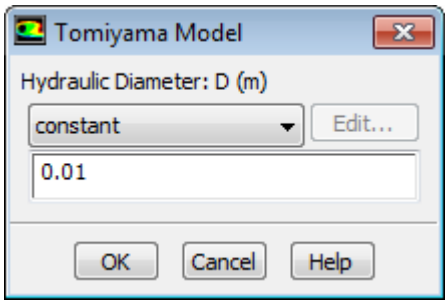
     
     The following model parameters are available:

     Coefficient: Cw1
     Specify the constant C_{w1} in Equation 17.269 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the `DEFINE_EXCHANGE_PROPERTY` macro (`DEFINE_EXCHANGE_PROPERTY`).

     Coefficient: Cw2
     Specify the constant C_{w2} in Equation 17.269 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the `DEFINE_EXCHANGE_PROPERTY` macro (`DEFINE_EXCHANGE_PROPERTY`).

   - Select **tomiyama** to use the Tomiyama model (Tomiyama Model in the Theory Guide). This model is only applicable for pipe geometries. You can enter the Hydraulic Diameter for your geometry in the **Tomiyama Model** dialog box (Figure 24.41: Tomiyama Model Dialog Box (p. 1468)).

     Figure 24.41: Tomiyama Model Dialog Box

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

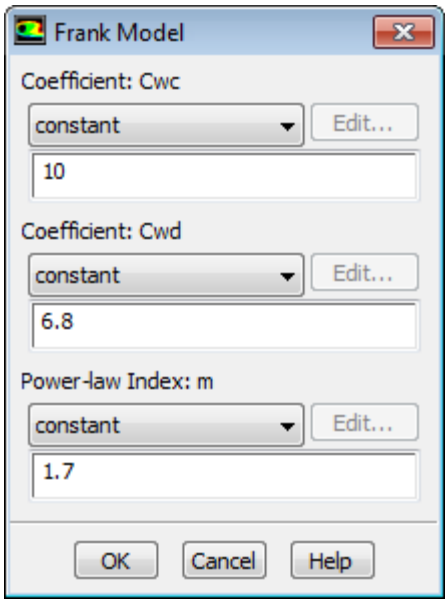
The following model parameters are available:

Hydraulic Diameter: D (m)
Specify the hydraulic diameter, D, in Equation 17.271 in the Theory Guide.

> **Important**
>
> The hydraulic diameter must be entered in units of meters.

- Select **frank** to use the Frank et al. model (Frank Model in the Theory Guide). You can edit the model parameters in the **Frank Model** dialog box (Figure 24.42: Frank Model Dialog Box (p. 1469)).

Figure 24.42: Frank Model Dialog Box



The following model parameters are available:

Coefficient: Cwc
Specify the cutoff coefficient, C_{wc}, in Equation 17.273 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

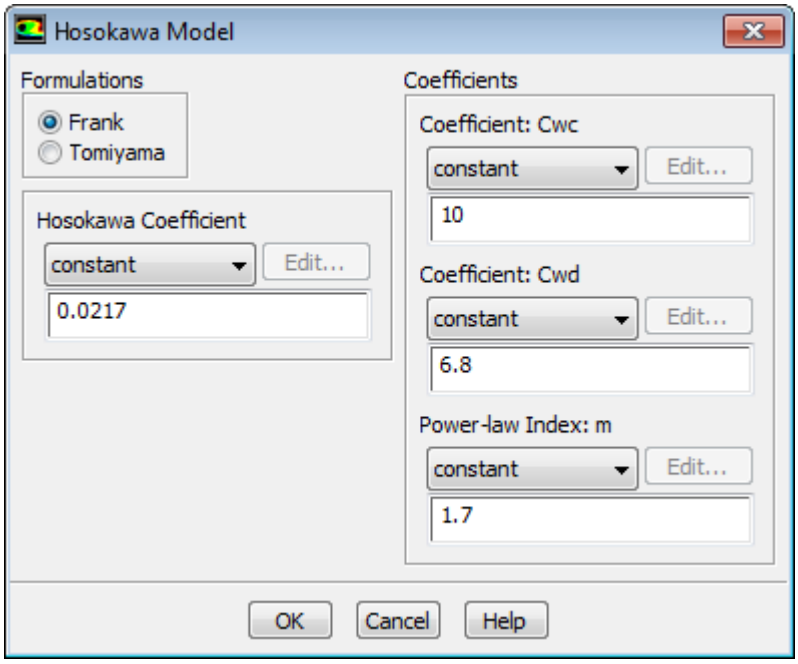
Coefficient: Cwd
Specify the damping coefficient, C_{wd}, in Equation 17.273 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

Power-law Index: m
Specify the power law constant, m, in Equation 17.273 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

- Select **hosakawa** to use the Hosokawa model (Hosokawa Model in the Theory Guide). You can edit the model parameters in the **Hosokawa Model** dialog box (Figure 24.43: Hosokawa Model Dialog Box (p. 1470)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.43: Hosokawa Model Dialog Box



The following model parameters are available:

Formulations
Select which formulation of the Hosokawa model to use. You can select either **Frank** or **Tomiyama**.

Hosokawa Coefficient
Specify the coefficient of the Eotvos number in Equation 17.274 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

Coefficients
Specify the model parameters associated with the formulation you selected under **Formulations**.

- Select **user-defined** to use a user-defined function for the wall lubrication coefficient (see DEFINE_EXCHANGE_PROPERTY in the *Fluent Customization Manual* for details).

24.5.2.5.5. Including the Turbulent Dispersion Force

For turbulent flows using the Eulerian multiphase model, you can include the effects of turbulent dispersion force ($\vec{F}_{td}$ in Equation 17.168 in the Theory Guide). The turbulent dispersion force acts as a turbulent diffusion in dispersed flows. For details on how turbulent dispersion is modeled in ANSYS Fluent see Turbulent Dispersion Force in the Theory Guide.

To include the effects of turbulent dispersion force, perform the following steps:

1. Click the **Turbulent Dispersion** tab to display the **Turbulent Dispersion** inputs.

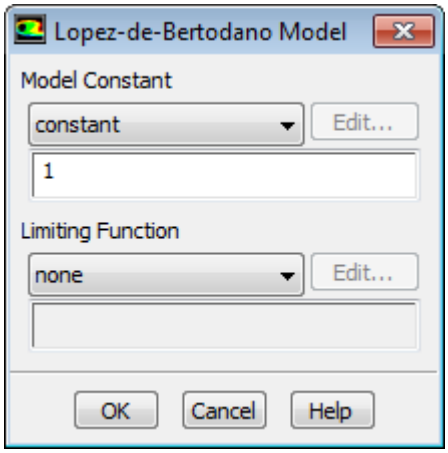
2. For each pair of phases, select the appropriate specification method from the corresponding drop-down list. Note that you will specify the turbulent dispersion only for pairs consisting of a secondary phase and the primary phase.

   - Select **none** (the default) to ignore the effects of turbulent dispersion.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select **lopez-de-bertodano** to use the Lopez de Bertodano model (Lopez de Bertodano Model in the Theory Guide). You can edit the model parameters in the **Lopez de Bertodano Model** dialog box (Figure 24.44: Lopez de Bertodano Model Dialog Box (p. 1471)).

Figure 24.44: Lopez de Bertodano Model Dialog Box



The following model parameters are available:

Model Constant

Specify the coefficient, C_{TD}, in Equation 17.278 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

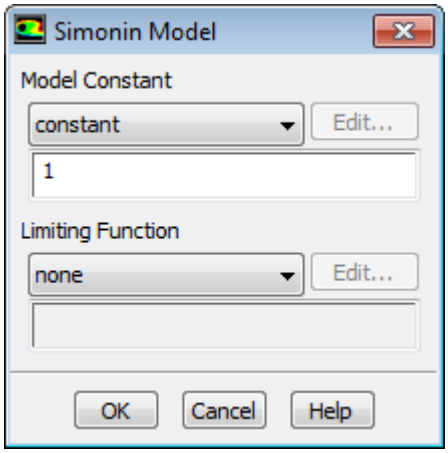
Limiting Function

Specify the limiting function to use. You may select **none**, the **standard** limiting function, or a **user-defined** function using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY). See Limiting Functions for the Turbulent Dispersion Force in Fluent Theory Guide for details on the limiting functions.

- Select **simonin** to use the Simonin model (Simonin Model in the Theory Guide).

You can specify the model parameters in the **Simonin Model** dialog box (Figure 24.45: Simonin Model Dialog Box (p. 1471)).

Figure 24.45: Simonin Model Dialog Box



The following model parameters are available:

Model Constant

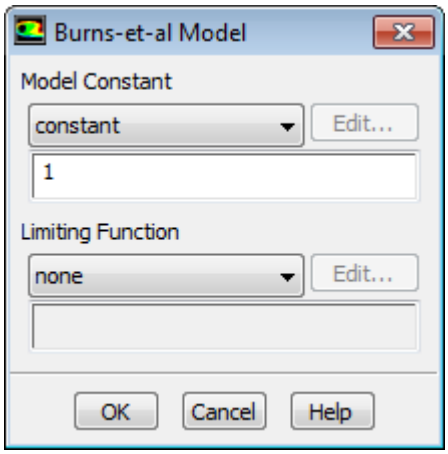
Specify the coefficient, C_{TD}, in Equation 17.280 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

Limiting Function

Specify the limiting function to use. You may select **none**, the **standard** limiting function, or a **user-defined** function using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY). See Limiting Functions for the Turbulent Dispersion Force in Fluent Theory Guide for details on the limiting functions.

- Select **burns-et-al** to use the Burns et al. model (Burns et al. Model in the Theory Guide). You can edit the model parameters in the **Burns-et-al Model** dialog box (Figure 24.46: Burns et al. Model Dialog Box (p. 1472)).

Figure 24.46: Burns et al. Model Dialog Box



The following model parameters are available:

Model Constant

Specify the coefficient, C_{TD}, in Equation 17.282 in the Theory Guide. You can enter a constant value or specify a user-defined function defined using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY).

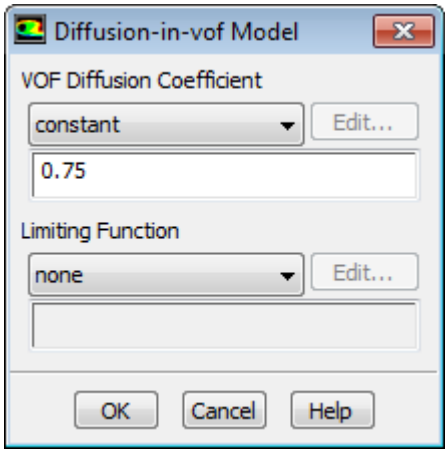
Limiting Function

Specify the limiting function to use. You may select **none**, the **standard** limiting function, or a **user-defined** function using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY). See Limiting Functions for the Turbulent Dispersion Force in Fluent Theory Guide for details on the limiting functions.

- Select **diffusion-in-vof** to use the Diffusion in VOF model (Diffusion in VOF Model in the Theory Guide). You can edit the model parameters in the **Diffusion-in-vof Model** dialog box (Figure 24.47: Diffusion—in—vof Model Dialog Box (p. 1473)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.47: Diffusion—in—vof Model Dialog Box



The following model parameters are available:

VOF Diffusion Coefficient
Specify the coefficient, σ_q, in Equation 17.285 in the Theory Guide.

Limiting Function
Specify the limiting function to use. You may select **none**, the **standard** limiting function, or a **user-defined** function using the DEFINE_EXCHANGE_PROPERTY macro (DEFINE_EXCHANGE_PROPERTY). See Limiting Functions for the Turbulent Dispersion Force in Fluent Theory Guide for details on the limiting functions.

- Select **user-defined** to use a user-defined function for the turbulent dispersion (see DEFINE_VECTOR_EXCHANGE_PROPERTY in the *Fluent Customization Manual* for details).

24.5.2.5.6. Including Surface Tension and Wall Adhesion Effects

As discussed in When Surface Tension Effects Are Important in the Theory Guide, the importance of surface tension effects depends on the value of the capillary number, Ca (defined by Equation 17.31 in the Theory Guide), or the Weber number, We (defined by Equation 17.32 in the Theory Guide). Surface tension effects can be neglected if $\mathrm{Ca} \gg 1$ or $\mathrm{We} \gg 1$.

Important

Note that the calculation of surface tension effects will be more accurate if you use a quadrilateral or hexahedral mesh in the area(s) of the computational domain where surface tension is significant. If you cannot use a quadrilateral or hexahedral mesh for the entire domain, then you should use a hybrid mesh, with quadrilaterals or hexahedra in the affected areas. ANSYS Fluent also offers an option to use VOF gradients at the nodes for curvature calculations on meshes when more accuracy is desired. For more information, see Surface Tension and Adhesion in the Theory Guide.

If you want to include the effects of surface tension along the interface between one or more pairs of phases, as described in Surface Tension and Adhesion in the Theory Guide, refer to Including Surface Tension and Adhesion Effects (p. 1438).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.5.2.5.7. Including the Virtual Mass Force

For both granular and non-granular flows, it is possible to include the "virtual mass force" ($\vec{F}_{vm}$ in Equation 17.288 in the Theory Guide) that is present when a secondary phase accelerates relative to the primary phase. The virtual mass effect is significant when the secondary phase density is much smaller than the primary phase density (for example, for a transient bubble column).

To include the effect of the virtual mass force perform the following steps:

1. Click the **Virtual Mass** tab to display the **Virtual Mass** inputs.

2. Enable **Virtual Mass Modeling**.

3. For each phase pair listed under **Virtual Mass Coefficient**, select the method for specifying the virtual mass coefficient, C_{vm}, in Equation 17.288 in the *Fluent Theory Guide*. You can choose from the following methods:

   none
   Disable virtual mass modeling for the phase pair.

   constant
   Specify a constant value for the coefficient. The default value of `0.5` is typical.

   user-defined
   Use a user-defined function created with the `DEFINE_EXCHANGE_PROPERTY` macro. See `DEFINE_EXCHANGE_PROPERTY` in the *Fluent Customization Manual* for details.

   Important

   No virtual mass effects will be included unless the **Virtual Mass Modeling** option is enabled.

4. If desired, you can enable the **Implicit** method for virtual mass.

   When using the **Implicit** method, the **Default** option uses the complete term in Equation 17.288. You can also choose **Option 2** or **Option 3**, which use locally truncated forms of the virtual mass terms in cells where divergence is detected.

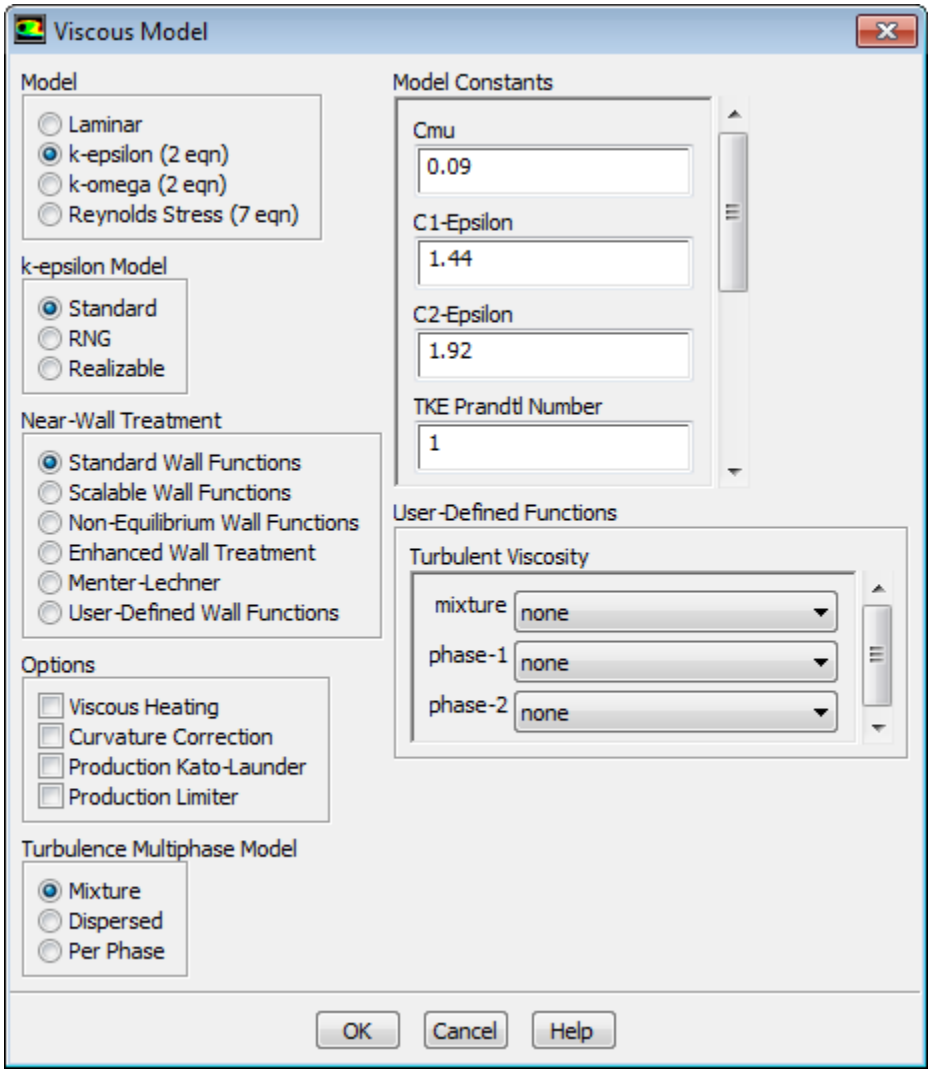
   The **Implicit** method is recommended for steady-state coupled simulations as it offers improved convergence in such cases. The recommended approach is to begin the simulation using **Option 2**. Once the solution has converged enough to establish the basic flow field, switch back to **Default** to include the complete virtual mass term.

24.5.3. Modeling Turbulence

If you are using the Eulerian model to solve a turbulent flow, you will need to choose one of turbulence models described in Turbulence Models in the Theory Guide in the Viscous Model Dialog Box (p. 2176) (Figure 24.48: The Viscous Model Dialog Box for an Eulerian Multiphase Calculation (p. 1475)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.48: The Viscous Model Dialog Box for an Eulerian Multiphase Calculation



The procedure is as follows:

1. Select **k-epsilon**, **k-omega**, or **Reynolds Stress** under **Model**.

2. Select the desired **k-epsilon Model**, **k-omega Model**, or **Reynolds-Stress Model** and any other related parameters, as described for single-phase calculations in Steps in Using a Turbulence Model (p. 764).

3. Under **Turbulence Multiphase Model** or **RSM Multiphase Model**, indicate the desired multiphase turbulence model (see Turbulence Models in the Theory Guide for details about each):

   - Select **Mixture** to use the mixture turbulence model. This is the default model.

   - Select **Dispersed** to use the dispersed turbulence model. This model is applicable when there is clearly one primary continuous phase and the rest are dispersed dilute secondary phases.

   - Select **Per Phase** to use a k-ε or k-ω turbulence model for each phase. This model is appropriate when the turbulence transfer among the phases plays a dominant role.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

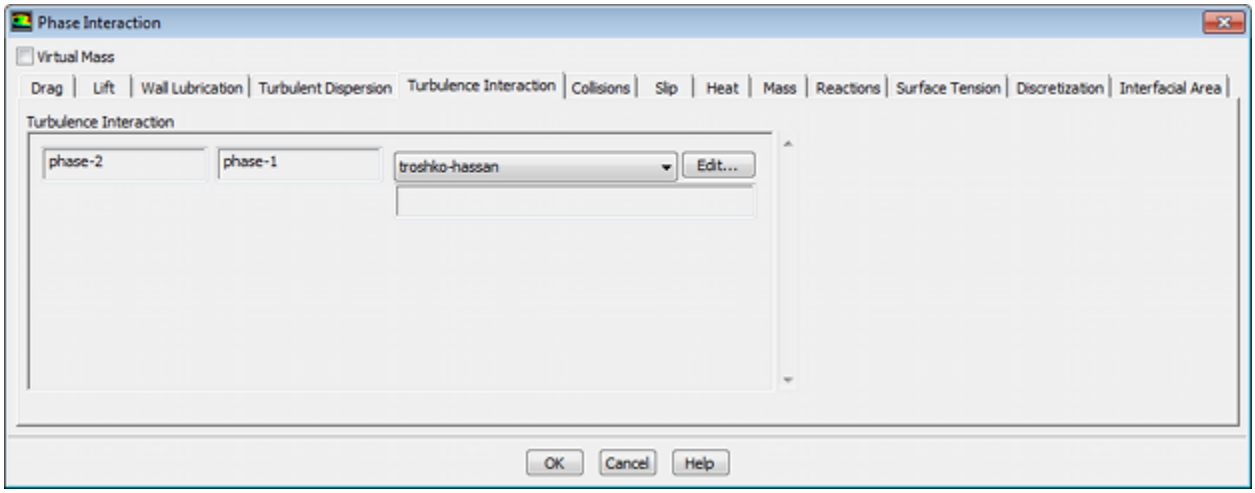
24.5.3.1. Including Turbulence Interaction Source Terms

By default, interphase turbulence source terms are not included in the calculation. If you want to include these source terms, you can enable them from the **Turbulence Interaction** tab of the Phase Interaction Dialog Box (p. 2363).

Setup → Models → Multiphase → Phases → Edit... → Interaction...

1. Click the **Interaction...** button to open the **Phase Interaction** dialog box (for example, Figure 24.49: The Phase Interaction Dialog Box for Turbulence Interaction (p. 1476)).

   Figure 24.49: The Phase Interaction Dialog Box for Turbulence Interaction



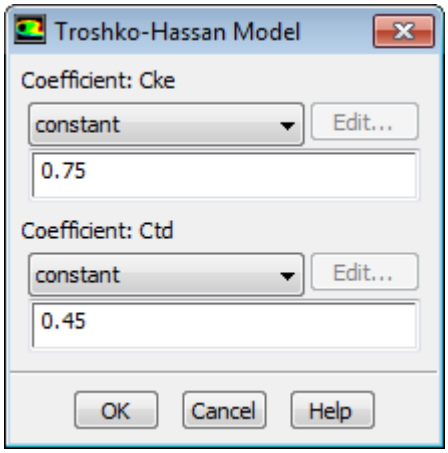
2. Click the **Turbulence Interaction** tab in the **Phase Interaction** dialog box.

3. For each pair of phases, select the desired correlation for the Turbulence Interaction. The available options are:

   - select **none** to omit turbulence interaction source terms. This is the default.
   - select **troshko-hassan** to use the Troshko-Hassan model described in Troshko-Hassan in the *Fluent Theory Guide*. You can edit the model parameters in the **Troshko-Hassan Model** dialog box (Figure 24.50: Troshko-Hassan Model Dialog Box (p. 1477)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.50: Troshko-Hassan Model Dialog Box



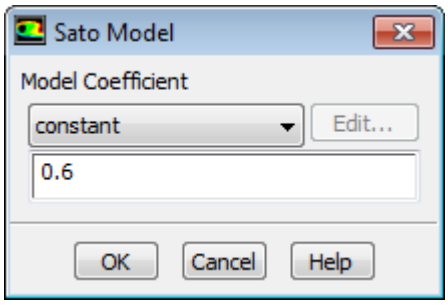
The following model parameters are available:

Coefficient: Cke
Specify the coefficient, C_{ke}, in the equations in Troshko-Hassan in the *Fluent Theory Guide*.

Coefficient: Ctd
Specify the coefficient, C_{td}, in the equations in Troshko-Hassan in the *Fluent Theory Guide*.

- select **sato** to use the Sato model described in Sato in the *Fluent Theory Guide*. You can edit the model parameters in the **Sato Model** dialog box (Figure 24.51: Sato Model Dialog Box (p. 1477)).

Figure 24.51: Sato Model Dialog Box



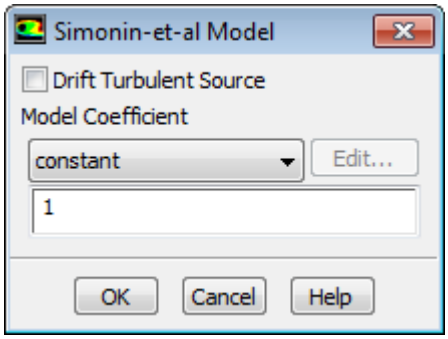
The following model parameters are available:

Model Coefficient
Specify the coefficient, $C_{\mu,p}$, in the equations in Sato in the *Fluent Theory Guide*.

- select **simonin-et-al** to use the Simonin et al. model described in Simonin et al. in the *Fluent Theory Guide*. This option is available only when **Dispersed** or **Per Phase** is selected in the **Viscous Model** dialog box. You can edit the model parameters in the **Simonin-et-al Model** dialog box (Figure 24.52: Simonin-et-al Model Dialog Box (p. 1478)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.52: Simonin-et-al Model Dialog Box



The following model parameters are available:

Drift Turbulent Source
include the portion the turbulent kinetic energy source term arising from the drift velocity.

Model Coefficient
Specify the coefficient, C_s, in the equations in Simonin et al. in the *Fluent Theory Guide*.

If you decide to enable turbulence interaction for multiple phase pairs, it is recommended that you avoid mixing the different models and that you select the same model for each phase pair with turbulence interaction enabled.

Note that the inclusion of these terms can slow down convergence noticeably. If you are looking for additional accuracy, you may want to compute a solution first without these sources, and then continue the calculation with these terms included. In most cases these terms can be neglected.

24.5.3.2. Customizing the k- ε Multiphase Turbulent Viscosity

If you are using the k- ε multiphase turbulence model, a user-defined function can be used to customize the turbulent viscosity for each phase. This option will enable you to modify μ_t in the k- ε model. For more information, see the Fluent Customization Manual.

In the **Viscous Model** dialog box, under **User-Defined Functions**, select the appropriate user-defined function in the **Turbulent Viscosity** drop-down list.

24.5.4. Including Heat Transfer Effects

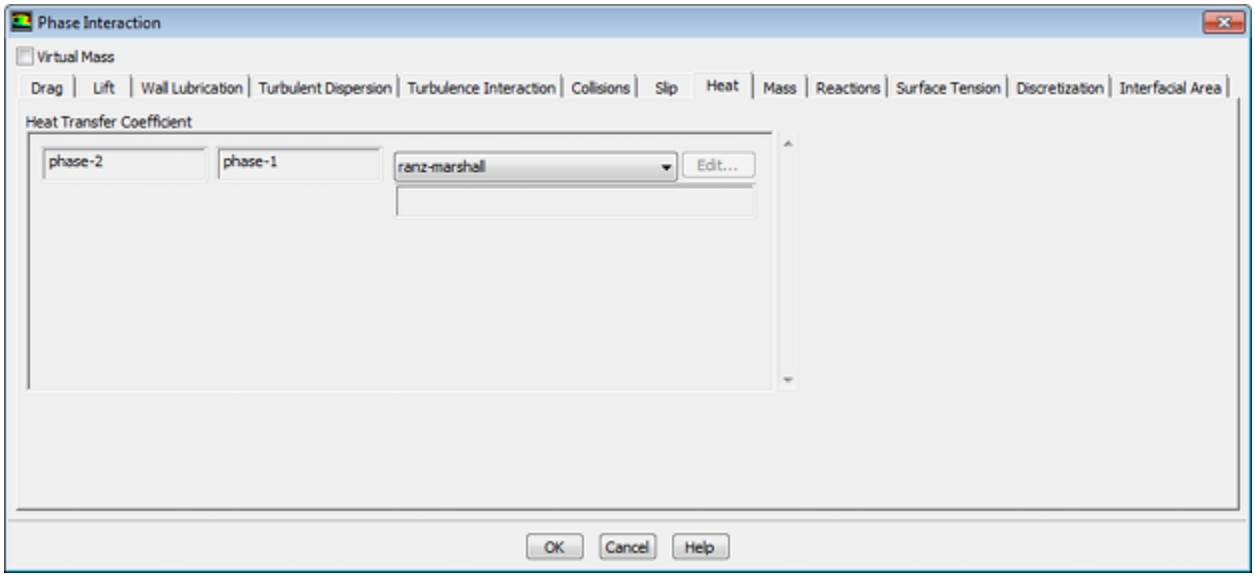
To define heat transfer in a multiphase Eulerian simulation, you will need to visit the **Phase Interaction** dialog box, after you have enabled the energy equation in the **Energy** dialog box.

Setup → Models → Multiphase → Phases → Edit... → Interaction...

1. Click the **Interaction...** button to open the **Phase Interaction** dialog box (for example, Figure 24.53: The Phase Interaction Dialog Box for Heat Transfer (p. 1479)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.53: The Phase Interaction Dialog Box for Heat Transfer



2. Click the **Heat** tab in the **Phase Interaction** dialog box.

3. Select the desired correlation for the **Heat Transfer Coefficient**. The available choices will depend upon what other models you have enabled. Note the following regarding the available choices:

   constant-htc
   allows you to specify a constant value for the volumetric heat transfer coefficient.

   nusselt-number
   allows you to specify a value for the Nusselt number from which the heat transfer coefficient will be computed.

   gunn
   is frequently used for Eulerian multiphase simulations involving a granular phase.

   ranz-marshall
   is frequently used for Eulerian multiphase simulations not involving a granular phase.

   hughmark
   is an extension of Ranz-Marshall to a wider range of Reynolds Number.

   tomiyama
   is frequently used for Eulerian multiphase simulations of bubbly flows with relatively low Reynolds number.

   none
   allows you to ignore the effects of heat transfer between the two phases.

   user-defined
   allows you to implement a correlation reflecting a model of your choice, through a user-defined function.

   two-resistance
   allows you to independently specify the heat transfer coefficient correlations for the two phases. This setting is recommended when using the evaporation-condensation mass transfer model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

fixed-to-sat-temp
models heat transfer when all of the heat transfer to a phase interface is used in mass transfer. It assumes that the temperature at the **To-Phase** in the mass transfer is equal to the saturation temperature. Note that this model only applies when one of the mass transfer models is enabled.

lavieville-et-al
is only available within the two-resistance formulation and can be used to model the gas-interface heat transfer coefficient. It assumes that the gas phase retains the saturation temperature by rapid evaporation or condensation.

zero-resistance
is only available within the two-resistance formulation. It may be specified for one phase in which case that phase temperature is equal to the interfacial temperature.

4. Set the appropriate thermal boundary conditions. You will specify the thermal boundary conditions for each individual phase on most boundaries, and for the mixture on some boundaries. See Cell Zone and Boundary Conditions (p. 237) for more information on boundary conditions, and Eulerian Model (p. 1401) for more information on specifying boundary conditions for a Eulerian multiphase calculation.

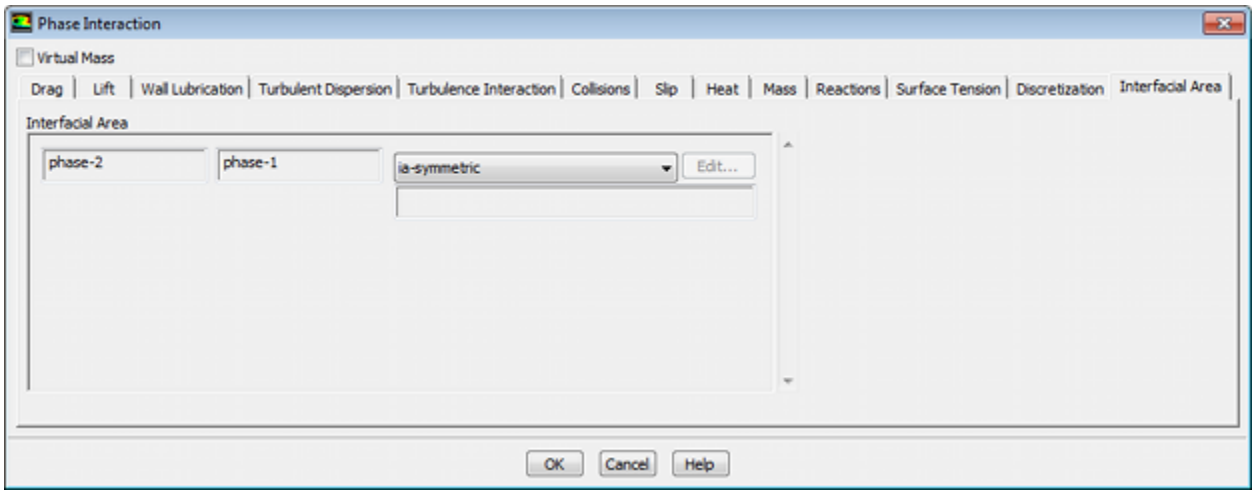
See Description of Heat Transfer in the Theory Guide for more information on heat transfer in the framework of a Eulerian multiphase simulation and the available models.

24.5.5. Using an Algebraic Interfacial Area Model

If you have chosen not to solve the transport equation for Interfacial Area Concentration (Defining the Interfacial Area Concentration (p. 1461)), you can select an algebraic model to estimate the interfacial area from the secondary phase diameter specified in the Secondary Phase Dialog Box (p. 2357). To choose an algebraic interfacial area model perform these steps.

1. Click the **Interaction...** button to open the **Phase Interaction** dialog box (for example, Figure 24.54: The Phase Interaction Dialog Box for Interfacial Area (p. 1480)).

Figure 24.54: The Phase Interaction Dialog Box for Interfacial Area



2. Click the **Interfacial Area** tab in the **Phase Interaction** dialog box.

3. Select the desired algebraic model for the **Interfacial Area**. Note the following regarding the available choices:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ia-symmetric
considers both the primary and secondary phase volume fractions in estimating the interfacial area.

ia-particle
considers only the secondary phase volume fraction in estimating the interfacial area.

Additional options are available if you have enabled one of the boiling models. See Including the Boiling Model (p. 1486).

See Interfacial Area Concentration in the *Fluent Theory Guide* for details about the algebraic interfacial area models.

24.5.6. Including the Dense Discrete Phase Model

If you are using the Eulerian multiphase model (Setting Up the Eulerian Model (p. 1455)), you have the option of including the **Dense Discrete Phase Model** (Dense Discrete Phase Model in the Theory Guide).

Important

- Enabling this model automatically enables the DPM model. You will notice that **Interaction with Continuous Phase** in the **Discrete Phase Model** dialog box is enabled.
- The Dense Discrete Phase model is available only with the **Eulerian** multiphase model. The limitations that currently apply to DPM and Eulerian multiphase models also apply to the Dense Discrete Phase model. See Limitations of the Eulerian Model in the *Fluent Theory Guide* and Limitations (p. 1238) for limitations that exist with the DPM and Eulerian multiphase models.

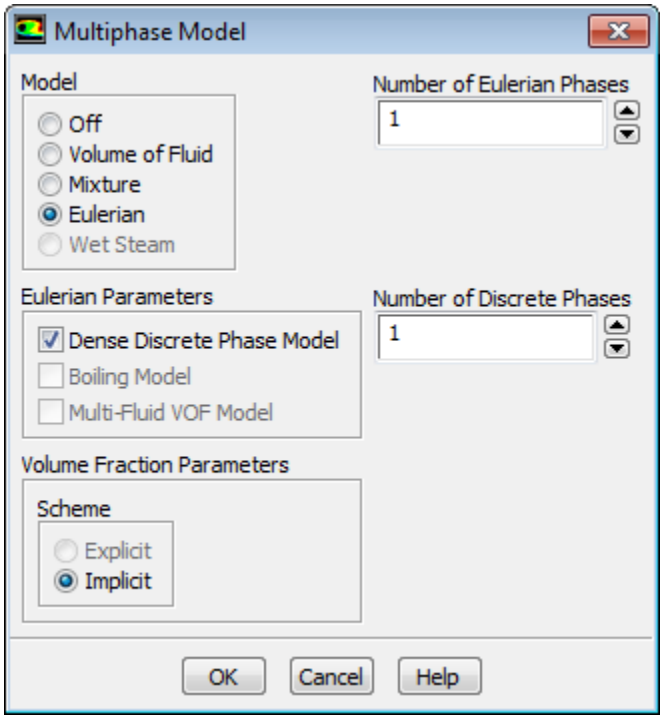
The required work flow when using the dense discrete phase model is as follows:

1. Set up the **Multiphase Model** dialog box (Figure 24.55: The Dense Discrete Phase Model (p. 1482)) to include the dense discrete phase model parameters.

   Setup → **Models** → **Multiphase** → **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.55: The Dense Discrete Phase Model



a. Enable **Dense Discrete Phase Model** under **Eulerian Parameters**.

b. Set the **Number of Discrete Phases** that are present in your case.

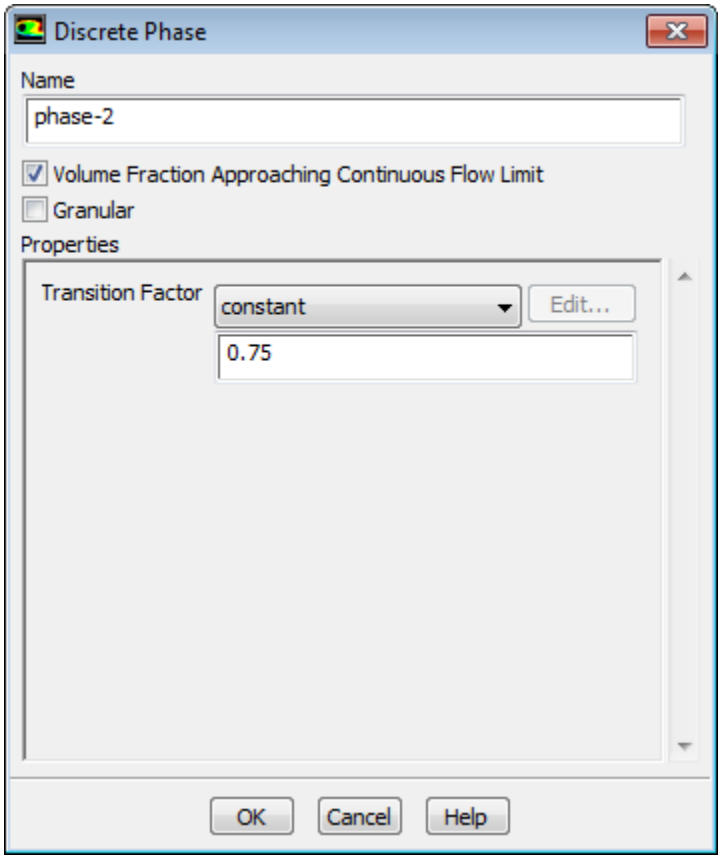
2. Open the **Phases** dialog box, in order to define the phases.

Setup → Models → Multiphase → Phases → Edit...

a. Define the discrete phase, by selecting the phase from the **Phases** selection list that is labeled **Discrete Phase** and clicking the **Edit...** button. Then set up the properties in the **Discrete Phase** dialog box that opens, as shown in Figure 24.56: The Discrete Phase Dialog Box (p. 1483).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.56: The Discrete Phase Dialog Box



Note that for non-granular flow, no additional inputs are required here (since the material is set automatically in the background, and the diameter is part of the solution).

b. Enable **Volume Fraction Approaching Continuous Flow Limit** to specify a **Transition Factor**. The **Transition Factor** is multiplied by the theoretical close-packing limit for mono-sized spheres ($\pi/3\sqrt{2} \approx 3/4$) to determine the transition volume fraction. The default value for the **Transition Factor** is 0.75, giving a transition volume fraction of 0.5625 ($=0.75*3/4$). Note that the **Transition Factor** is not limited to a range between 0 and 1. In other words, you can specify values outside this range. For example, a value of 1.2 will give a transition volume fraction of 0.9. You can also specify locally variable values using the `DEFINE_PROPERTY` user-defined macro, depending on the local particle size distribution, as an example.

See `DEFINE_PROPERTY` UDFs in the Fluent Customization Manual for information about the `DEFINE_PROPERTY`.

c. Define the primary and secondary phases, as described in Defining the Phases for the Eulerian Model (p. 1456).

3. Define the injections using the **Injections** dialog box.

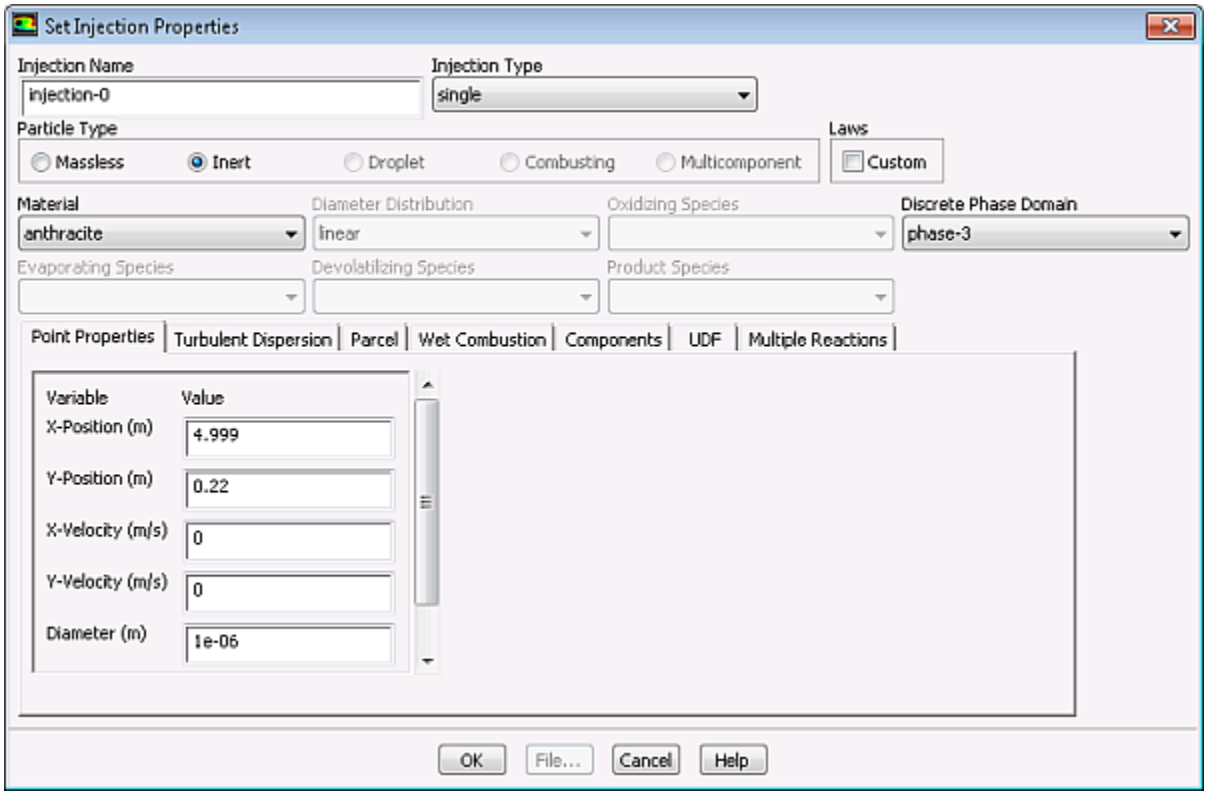
Setup → Models → Discrete Phase → Injections → New...

a. Create a new injection by clicking the **Create** button in the **Injections** dialog box, or edit an existing injection by selecting the injection from the **Injections** list and clicking the **Set...** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. In the **Set Injection Properties** dialog box that opens (Figure 24.57: The Set Injection Properties Dialog Box (p. 1484)), specify properties for each injection as described in Setting Initial Conditions for the Discrete Phase (p. 1265)

Figure 24.57: The Set Injection Properties Dialog Box



Note

Note that when the DDPM is used, **averaged-discrete-phase-drag** is automatically selected for the drag coefficient in the **Drag** tab of the **Phase Interaction** dialog box. **averaged-discrete-phase-drag** corresponds to K_{DPM} in Equation 17.403 in the *Fluent Theory Guide* and indicates that the interaction between discrete and fluid phases will be computed based on averaged values of fluid drag of all particles crossing the fluid cell. That is, at each time step, the drag is evaluated for each particle using the drag law that you have selected in the **Set injection Properties** dialog box and then averaged based on the residence time of each particle in the cell.

c. Select the discrete phase from the **Discrete Phase Domain** drop-down list.

4. Define the material properties for each injection.

Setup → Materials

24.5.6.1. Defining a Granular Discrete Phase

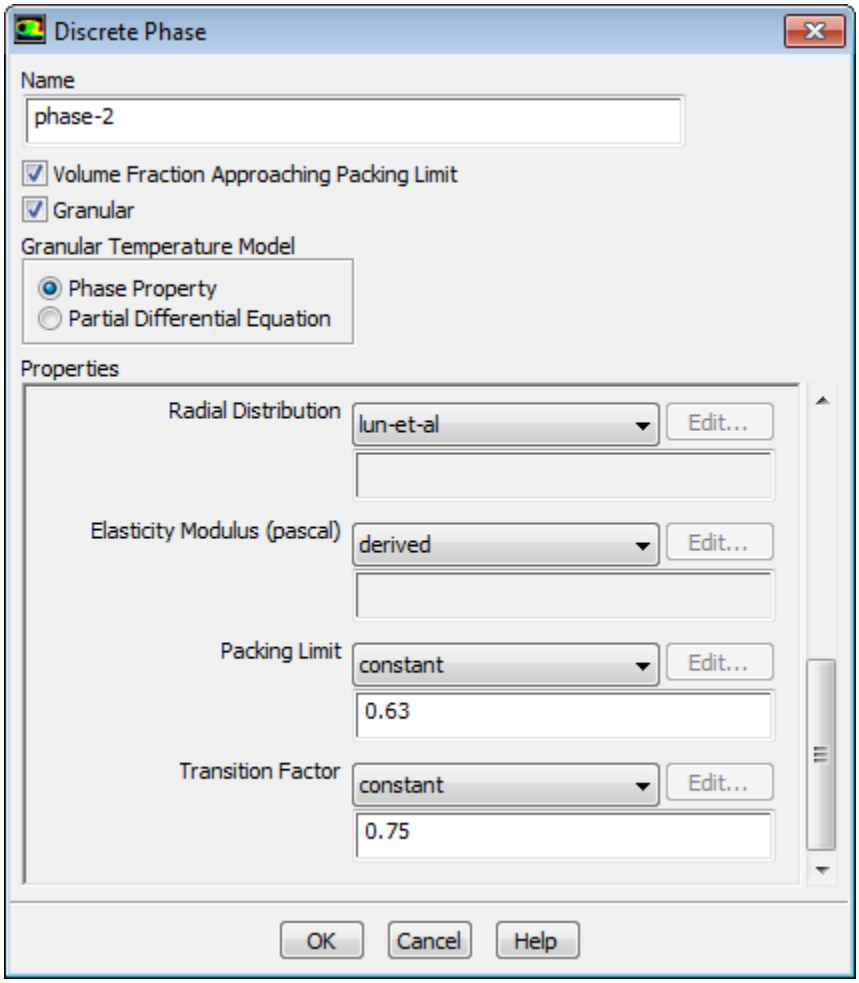
To define a granular (that is, particulate) discrete phase in an Eulerian multiphase calculation, perform the following steps:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Select the phase (for example, **Discrete Phase**) in the **Phases** list.

2. Click **Edit...** to open the **Discrete Phase** dialog box (Figure 24.58: The Discrete Phase Dialog Box for a Granular Phase (p. 1485)).

Figure 24.58: The Discrete Phase Dialog Box for a Granular Phase



3. In the **Discrete Phase** dialog box, enter a **Name** for the phase.

4. Enable the **Granular** option.

5. Enable **Volume Fraction Approaching Packing Limit** to prevent the unlimited accumulation of particles, which are operating at packing limit conditions.

6. Specify the **Transition Factor** as either a **constant** or a **user-defined** function. The default value for the **Transition Factor** is 0.75. The transition criterion is based on the local particle volume fraction of the given discrete phase and is specified as a factor multiplied by the maximum packing limit (also a user-specified value). For example, for a typical granular phase with a maximum packing limit of 0.63, the transition volume fraction is the product of 0.75 and 0.63, which is equal to 0.4725.

You can now define all other fields of the discrete phase in a similar manner to that described in Defining a Granular Secondary Phase (p. 1457).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.5.7. Including the Boiling Model

If you are using the Eulerian multiphase model (Setting Up the Eulerian Model (p. 1455)), you have the option of including the **Boiling Model** (see Wall Boiling Models in the Theory Guide).

Note the following limitations:

- This model is only available with the **Eulerian** multiphase model.
- This model is only available with the **Pressure-Based** solver.

The required work flow when using the boiling model is as follows:

1. Open the **Multiphase Model** dialog box (Figure 24.59: The Boiling Model (p. 1486)).

   Setup → **Models** → **Multiphase** → **Edit...**

   Figure 24.59: The Boiling Model

   a. Enable **Boiling Model** under **Eulerian Parameters**.

   b. Select **RPI Boiling Model**, **Non-equilibrium Boiling**, or **Critical Heat Flux** as the boiling model option. Information about the three options is available in RPI Model, Non-equilibrium Subcooled Boiling, and Critical Heat Flux in the Theory Guide.

   c. Set the total **Number of Eulerian Phases** that are present in your case. This can consist of two phases: liquid and vapor, which are directly involved in boiling mass transfer; or it can include "non-boiling

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

phases" or "species". If a system consists of three phases: liquid, vapor, and air, then the **Number of Eulerian Phases** will be 3, where air is the non-boiling phase.

Note

- To include the liquid volume fraction effects, use the `solve/set/multiphase-numeric/boiling-parameters/liquid-vof-factor` text command. When this option is enabled, the heat transfer coefficients of boiling models will be multiplied by the local liquid volume fraction.
- To include the thin film effects, use the `solve/set/multiphase-numeric/boiling-parameters/thin-film` text command. When enabled, this option will use Equation 17.433 in the *Fluent Theory Guide* in the calculation.

2. Make sure the energy option is enabled.

Note

The energy option will be automatically turned on when the boiling model is enabled.

Setup → Models → Energy → On

3. Enable **Gravity** and set the **Operating Pressure** in the **Operating Conditions** dialog box.

Important

Make sure gravity is included when the boiling model is used.

4. Choose one of the turbulence models that is available with the Eulerian multiphase model.

Setup → Models → Viscous → Edit...

5. Open the **Create/Edit Materials** dialog box and specify the material properties for the liquid, vapor, solid, and any other phases that may exist.

Setup → Materials → Fluid → Create/Edit...

Important

For the liquid and vapor phases, the **Standard State Enthalpy** must be specified, as it is used in the computation of the **Latent Heat**.

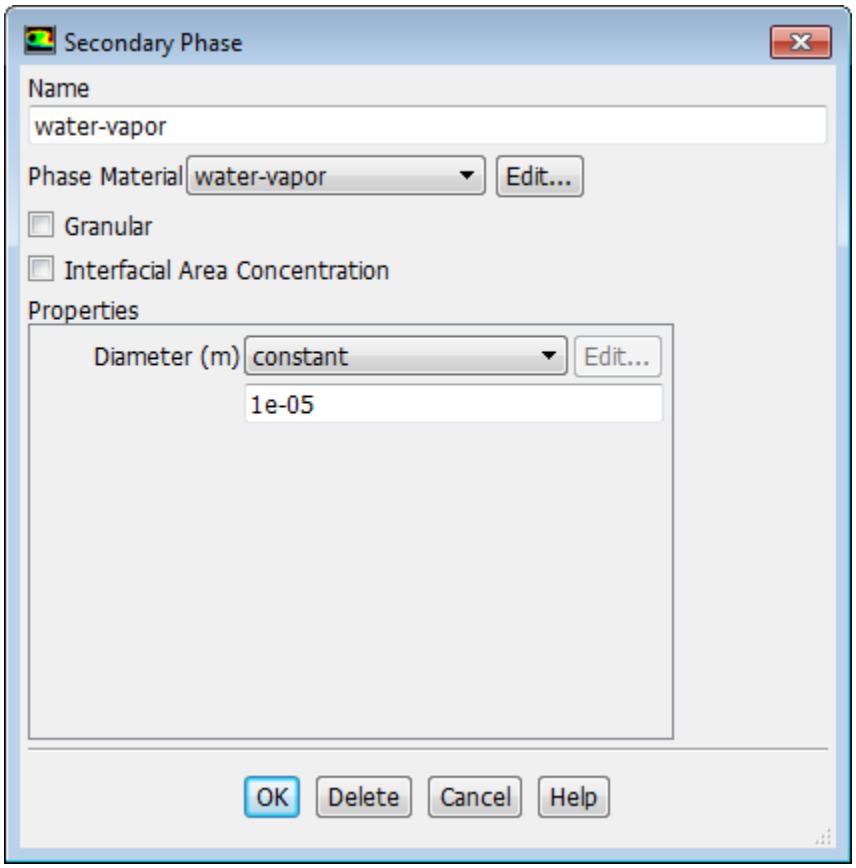
6. Open the **Phases** dialog box, in order to define the phases.

Setup → Models → Multiphase → Phases → Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Define the liquid as the primary phase by selecting the phase from the **Phases** selection list that is labeled **Primary Phase** and clicking the **Edit...** button. Define the vapor as the secondary phase. In the **Secondary Phase** dialog box, the **Diameter** is set to **boiling-dia** by default, but you have the option of setting it up as a **constant** value or a **user-defined** function, as shown in Figure 24.60: The Secondary Phase Dialog Box (p. 1488).

Figure 24.60: The Secondary Phase Dialog Box



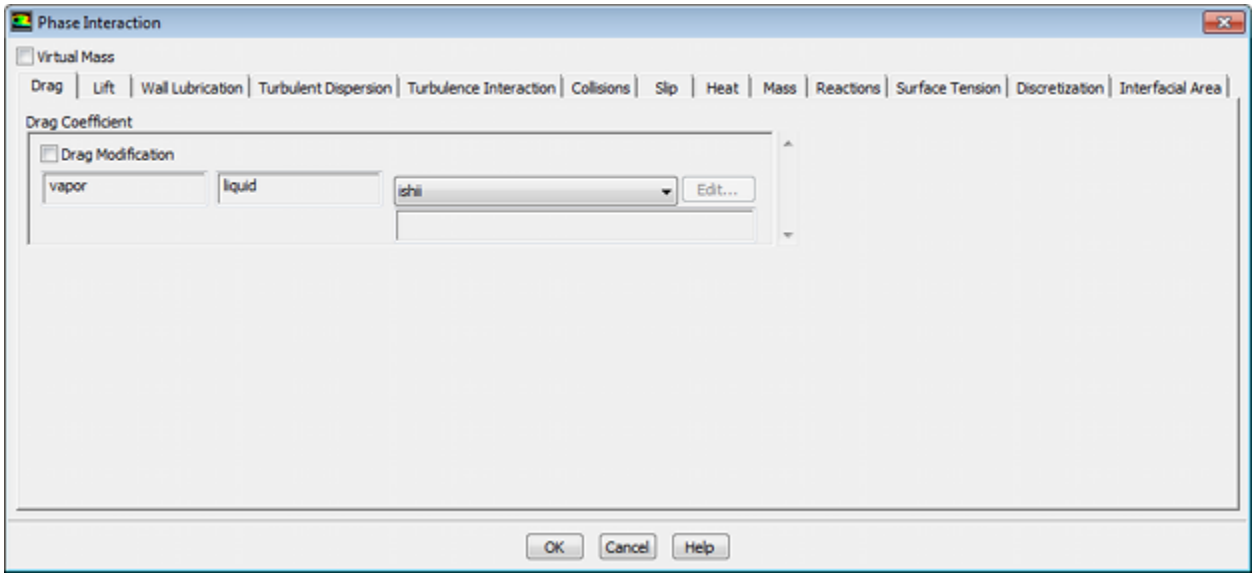
7. Open the **Phase Interaction** dialog box.

   Setup → **Models** → **Multiphase** → **Phases** → **Edit...** → **Interaction...**

   a. In the **Drag** tab, you have a choice of **ishii**, **universal-drag**, **schiller-naumann**, **symmetric**, **morsi-alexander**, **grace**, **tomiyama**, or **user-defined**. See Specifying the Drag Function (p. 1463) for definitions of the drag options For boiling flows, **ishii** is usually chosen.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.61: The Phase Interaction Dialog Box



b. In the **Lift** tab, select **moraga**, **tomiyama**, **saffman-mei**, **legendre-magnaudet**, or **user-defined**. For boiling flows, **tomiyama** is usually chosen.

c. In the **Wall Lubrication** tab, select **antal-et-al**, **tomiyama-et-al**, **frank**, **hosokawa**, or **user-defined** as described in Including the Wall Lubrication Force (p. 1467). For boiling flows, **antal-et-al** is typically chosen.

d. In the **Turbulent Dispersion** tab, select **lopez-de-bertodano**, **simonin**, **burns-et-al**, **diffusion-in-vof**, or **user-defined** as described in Including the Turbulent Dispersion Force (p. 1470). For boiling flows, **lopez-de-bertodano** is typically chosen.

e. In the **Turbulent Interaction** tab, select **troshko-hassan**, **sato**, or **simonin-et-al** as described in Including Turbulence Interaction Source Terms (p. 1476). For boiling flows, **troshko-hassan** is typically chosen.

f. In the **Heat** tab, select **ranz-marshall**, **tomiyama**, or **user-defined**. For boiling flows, **ranz-marshall** is usually chosen.

g. In the **Surface Tension** tab, select **constant** and enter the desired value.

h. In the **Interfacial Area** tab, you have four formulations available from which to select:

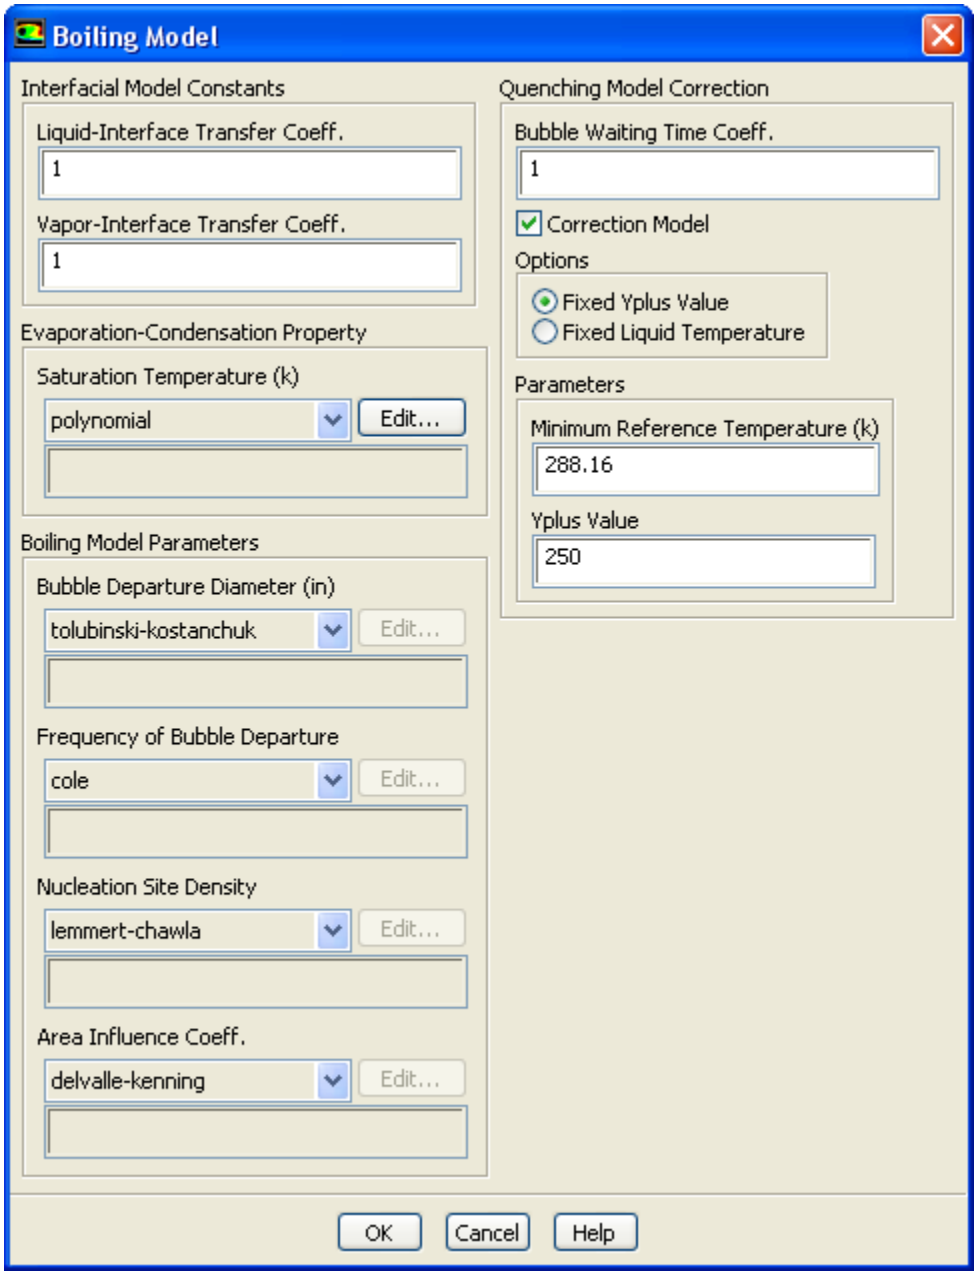
- **ia-symmetric** (default) (see Equation 17.177 in the Theory Guide)
- **ia-particle** (see Equation 17.176 in the Theory Guide)
- **ia-ishii** (see Equation 17.178 in the Theory Guide). This option is only available with the RPI model.
- **user-defined** (see Example 4- Custom Interfacial Area in the Fluent Customization Manual)

For boiling flows, **ia-symmetric** or **ia-particle** are usually chosen.

i. In the **Mass** tab, set the **Number of Mass Transfer Mechanisms** to 1 and make sure the transfer is always from the liquid to the vapor phase. Select **boiling** under **Mechanism**. The **Boiling Model** dialog box will open (Figure 24.62: The Boiling Model Dialog Box (p. 1490)), where you will set the boiling model parameters and the quenching model corrections.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.62: The Boiling Model Dialog Box



i. Specify the **Interfacial Model Constants** and the **Saturation Temperature**. The default values for the liquid and vapor interface transfer coefficients are 1.

Note

- If you use the **polynomial**, **piecewise-polynomial**, or **piecewise-linear** option for **Saturation Temperature**, the pressure-dependency must be specified in terms of absolute pressure.
- If you selected the **RPI Boiling Model** in the **Multiphase Model** dialog box, then you will not need to specify the **Vapor-Interface Transfer Coeff.**, since the vapor phase temperature is fixed to the saturation temperature.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ii. Under the **Boiling Model Parameters**, select the **Bubble Departure Diameter** that best describes your model. Five options exist: **tolubinski-kostanchuk** (the default setting), **unal**, **kocamustafaogullari-ishii**, **constant**, and **user-defined**. The **tolubinski-kostanchuk** formulation is described in Equation 17.421 in the Theory Guide, the **unal** formulation is described in Equation 17.423 in the Theory Guide and the **kocamustafaogullari-Ishii** formulation is described in Equation 17.419 in the Theory Guide.

iii. Specify the **Frequency of Bubble Departure**. You can choose the **cole** option (which is the default), or enter a **constant** value. The **cole** formulation is described in Equation 17.417 in the Theory Guide.

iv. Specify the **Nucleation Site Density**. You can choose between **lemmert-chawla** (which is the default), **kocamustafaogullari-ishii**. and **user-defined**. This quantity is usually represented by a correlation based on the wall superheat, described in Equation 17.418 in the Theory Guide.

Note

It is recommended that when using the **kocamustafaogullari-ishii** option, it should be used for both the **Bubble Departure Diameter** and **Nucleation Site Density**.

---

v. Specify the **Area Influence Coeff.** The area of influence is based on the bubble departure diameter and the nucleate site density, as defined in Equation 17.414 in the Theory Guide. You have a choice of three options when modeling the area of influence coefficient: **delvalle-kenning** (which is the default and defined in Equation 17.415 in the Theory Guide, **constant**, and **user-defined**.

vi. The **Quenching Correction Model** addresses the quenching term in the wall heat flux partition (described in Wall Heat Flux Partition in the Theory Guide). The quenching term in the wall heat flux partition models the cyclic averaged transient energy transfer related to liquid filling the wall vicinity after the bubble detachment with a period T and it is expressed as:

$$\dot{q}_q = C_{wt} \frac{2k_l}{\sqrt{\pi \gamma_l T}} \left(T_w - T_l\right) A_b \tag{24.15}$$

where k_l is the liquid heat conductivity, T is the periodic time, and $\gamma_l = k_l \Big/ \left(\rho_l c_{pl}\right)$ is the liquid phase diffusivity. The **Bubble Waiting Time Coefficient**, C_{wt}, is a coefficient introduced to correct the waiting time between departures of consecutive bubbles. The default value is 1, however you can modify this value as needed, but it can only be specified as a constant.

From Equation 24.15 (p. 1491), you can see that the quenching model is strongly dependent on T_l, which results in grid-dependent solutions. To remedy this, two approaches have been adopted in ANSYS Fluent: **Fixed Yplus Value** and **Fixed Liquid Temperature**.

vii. Enable the **Correction Model** if you want to achieve a certain level of gird-independence in your solution. If this option is disabled, Equation 24.15 (p. 1491) calculates the quench flux term without corrections.

viii. Select **Fixed Yplus Value** if you want to use the logarithmic form of the wall functions to estimate the liquid temperature T_l at a fixed Yplus value of 250, as proposed by Egorov and Mentor [27] (p. 2888), instead of using the liquid temperature values in the near-wall cells. Enter the **Minimum Reference Temperature**, which limits the lowest value of the liquid temperature. It should not be lower than the liquid inlet temperature. Specify a **Yplus Value**. It is set to 250 by default.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ix. If you select **Fixed Liquid Temperature**, you can choose from **standard**, **constant**, or **user-defined** for the **Liquid Reference Temperature**. You will also need to enter the **Minimum Reference Temperature**. The liquid temperature used to compute the quenching flux should usually be between the inlet liquid temperature and the saturation temperature.

Note

To learn how to hook boiling parameter user-defined functions, refer to `DEFINE_BOILING_PROPERTY` in the Fluent Customization Manual.

8. Set up the conditions at inlets, outlets, and thermal conditions for walls.

Setup → **Boundary Conditions**

For the quenching wall heat flux, Koncar et al. [54] (p. 2890) have suggested that in order to avoid grid dependence when calculating the quenching heat transfer, a factor that relates the temperature at a fixed normalized distance (y+ = 250) to the temperature at the near wall cell must be applied. Contact a technical support engineer for more information.

The wall boiling models are compatible with three different wall boundaries: isothermal wall, specified heat flux, and specified heat transfer coefficient (coupled wall boundary).

Note

The boiling models do not apply to thin walls.

9. Choose **Coupled** as the pressure-velocity coupling scheme.

Solution → **Methods**

Note

Although **Phase Coupled SIMPLE** is also available, it is generally less robust and is not recommended for use in steady cases involving boiling or mass transfer.

10. The following solution strategies are recommended for boiling model simulations:

Solution → **Controls**

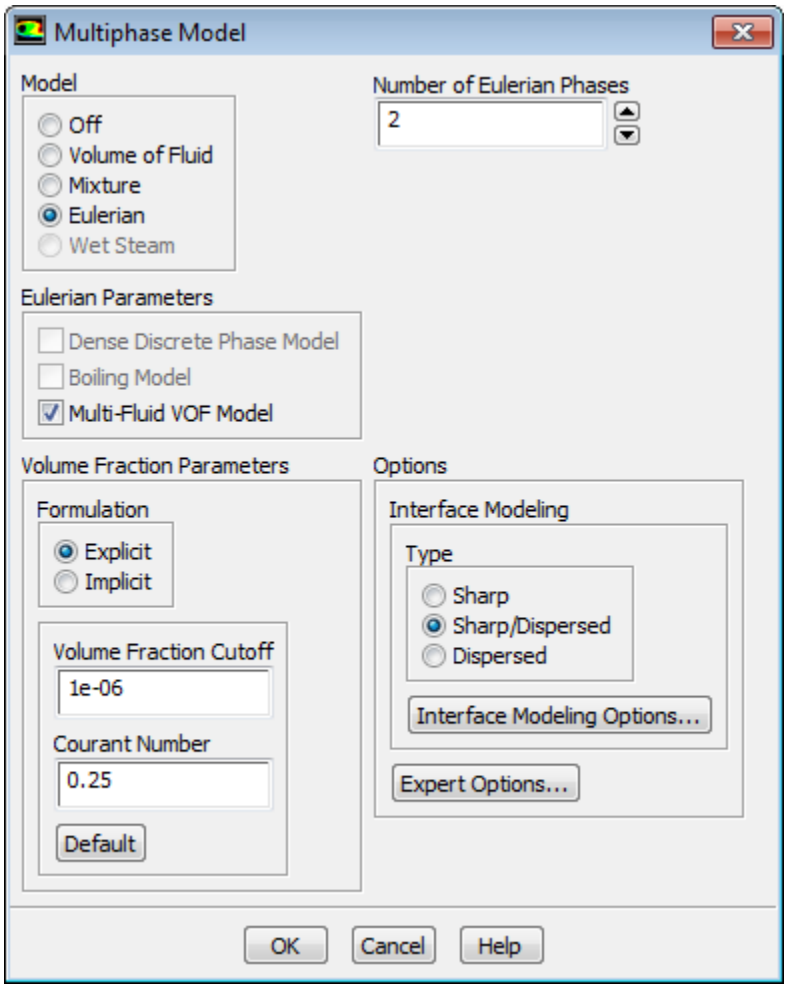
- **Courant Number**: use a value between 1 and 20 is recommended. As a first try, use a value of 10.
- **Explicit Relaxation Factors**: use the default values of 1 for **Momentum** and **Pressure**.
- **Vaporization Mass**: use an under-relaxation factor between 0.5 and 1. As a first try, use a value of 1.
- **Volume Fraction**: use an under-relaxation factor between 0.3 and 0.5.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Turbulent Kinetic Energy**: use an under-relaxation factor between 0.3 and 0.8.
- **Turbulent Viscosity**: use an under-relaxation factor between 0.5 and 1.0.
- **Energy**: use an under-relaxation factor between 0.5 and 0.8.

24.5.8. Including the Multi-Fluid VOF Model

After you have selected the Eulerian multiphase model (Setting Up the Eulerian Model (p. 1455)), you can enable the **Multi-Fluid VOF Model** (Multi-Fluid VOF Model in the Theory Guide).



Note the following limitations:

- This model is only available with the **Eulerian** multiphase model.
- You cannot use this model with the **Dense Discrete Phase Model**.

After enabling **Multi-Fluid VOF**, the **Interface Modeling Options** become available, as described in Interface Modeling Type (p. 1371). You can select from **Sharp**, **Dispersed**, or hybrid **Sharp/Dispersed** interface modeling to expose the most appropriate discretization schemes for your simulation. You can also specify some additional time-advancement settings as described in Setting Time-Dependent Parameters for the Explicit Volume Fraction Formulation (p. 1445).

The available drag laws depend on your selection for **Interface Modeling**. **Sharp** interface modeling supports only **symmetric**, **anisotropic-drag**, **user-defined**, and **none**. **Sharp/Dispersed** interface

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

modeling supports all the relevant drag laws. **Dispersed** interface modeling does not support **anisotropic-drag**, but supports all other relevant drag laws.

Note

Anisotropic drag applicable to free surface modeling is only compatible with the **Mixture** turbulence model.

If you want to use the anisotropic drag law, perform the following steps:

1. Define the drag law in the **Phase Interaction** dialog box.

   Setup → **Models** → **Multiphase** → **Phases** → **Edit...** → **Interaction...**

2. Click the **Drag** tab to display the **Drag Coefficient** inputs.

3. For each pair of phases, select the appropriate drag law from the corresponding drop-down list.

   - Select **anisotropic-drag** when there is higher drag in the normal direction to the interface and lower drag in the tangential direction to the interface. For details about this drag law, refer to Multi-Fluid VOF Model in the Theory Guide.

     To specify the input parameters for anisotropic drag, you will need to use the `/solve/set/mp-mfluid-aniso-drag` text command. The options for an `Anisotropic Drag Method` of `0` (which is based on the symmetric drag), are as follows:

     ```
     Anisotropic Drag Method
       [0]

     Normal Interfacial Drag Friction Factor
       [1000000]

     Tangential Interfacial Drag Friction Factor
       [10]

     Length scale
       [0.0001]
     ```

     The options for an `Anisotropic Drag Method` of `1` are as follows:

     ```
     Anisotropic Drag Method
       [0] 1

     Viscosity option
       [2]

     Normal Interfacial Drag Friction Factor
       [1000000]

     Tangential Interfacial Drag Friction Factor
       [10]

     Length scale
       [0.0001]
     ```

4. If you have enabled **Phase Localized Discretization** in the **Multiphase Model** dialog box, click the **Discretization** tab to enable the use of the **Phase Localized Compressive Scheme**. For information about applying the various schemes, refer to Discretizing Using the Phase Localized Compressive Scheme (p. 1443).

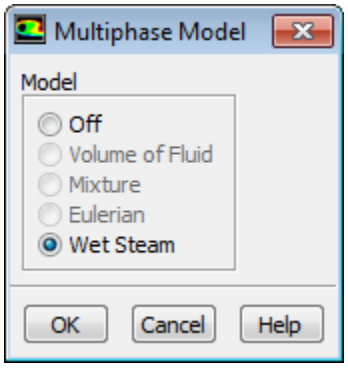
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.6. Setting Up the Wet Steam Model

After you have enabled the density-based solver in ANSYS Fluent, you can choose the wet steam model (see Wet Steam Model Theory in the Theory Guide) by opening the **Multiphase Model** dialog box and selecting the **Wet Steam** option.

Setup → Models → Multiphase → Edit...

Figure 24.63: The Multiphase Model Dialog Box with the Wet Steam Model Selected



This section includes information about using your own property functions and data with the wet steam model. Solution settings and strategies for the wet steam model can be found in Wet Steam Model (p. 1518). Postprocessing variables are described in Model-Specific Variables (p. 1520).

This section is organized as follows:

24.6.1. Using User-Defined Thermodynamic Wet Steam Properties
24.6.2. Writing the User-Defined Wet Steam Property Functions (UDWSPF)
24.6.3. Compiling Your UDWSPF and Building a Shared Library File
24.6.4. Loading the UDWSPF Shared Library File
24.6.5. UDWSPF Example

24.6.1. Using User-Defined Thermodynamic Wet Steam Properties

ANSYS Fluent allows you to use your own property functions and data with the wet steam model. This is achieved with user-defined wet steam property functions (UDWSPF).

These user-defined functions are written in the C programming language and there is a certain programming format that must be used so that you can build a successful library that can be loaded into the ANSYS Fluent code.

The following is the procedure for using the user-defined wet steam property functions (UDWSPF):

1. Define the wet steam equation of state and all related thermodynamic and transport property equations.
2. Create a C source code file that conforms to the format defined in this section.
3. Start ANSYS Fluent and set up your case file in the usual way.
4. Turn on the wet steam model.
5. Compile your UDWSPF C functions and build a shared library file using the text user interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`define` → `models` → `multiphase` → `wet-steam` → `compile-user-defined-wetsteam-functions`

6. Load your newly created UDWSPF library using the text user interface.

   `define` → `models` → `multiphase` → `wet-steam` → `load-unload-user-defined-wet-steam-library`

7. Run your calculation.

Important

Note that the UDWSPF can only be used when the wet steam model is selected. Therefore, the UDWSPF are available for use with the density-based solver only.

24.6.2. Writing the User-Defined Wet Steam Property Functions (UDWSPF)

Creating a UDWSPF C function library is reasonably straightforward:

- The code must contain the `udf.h` file inclusion directive at the beginning of the source code. This allows the definitions for `DEFINE` macros and other ANSYS Fluent functions to be accessible during the compilation process.
- The code must include at least one in the UDF's `DEFINE` functions (that is `DEFINE_ON_DEMAND`) to be able to use the compiled UDFs utility.
- Any values that are passed to the solver by the UDWSPF or returned by the solver to the UDWSPF are assumed to be in SI units.
- You must use the principle set of user-defined wet steam property functions in your UDWSPF library, as described in the list that follows. These functions are the mechanism by which your thermodynamic property data is transferred to the ANSYS Fluent solver.

The following lists the user-defined wet steam property function names and arguments, as well as a short description of their functions. Function inputs from the ANSYS Fluent solver consist of one or more of the following variables: T = temperature (K), P = pressure (Pa), and ρ = vapor-phase density (kg/m^3).

- `void wetst_init(Domain *domain)`

  This will be called when you load the UDWSPF. You use it to initialize wet steam model constants or your own model constants. It returns nothing.

- `real wetst_satP(real T)`

  This is the saturated pressure function, which takes on temperature in K and returns saturation pressure in Pa.

- `real wetst_satT(real P, real T)`

  This is the saturated temperature function, which takes on pressure in Pa and a starting guess temperature in K and returns saturation temperature in K.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- `real wetst_eosP(real rho, real T)`

  This is the equation of state, which takes on vapor density in kg/m^3 and Temperature in K and returns pressure in Pa.

- `real wetst_eosRHO(real P, real T)`

  This is the equation of state, which takes on pressure in Pa and temperature in K and returns vapor density in kg/m^3.

- `real wetst_cpv(real T, real rho)`

  This is the vapor specific heat at constant pressure, which takes on temperature in K and vapor density in kg/m^3 and returns specific heat at constant pressure in J/kg/K.

- `real wetst_cvv(real T, real rho)`

  This is the vapor specific heat at constant volume, which takes on temperature in K and vapor density in kg/m^3 and returns specific heat at constant volume in J/kg/K.

- `real wetst_hv(real T,real rho)`

  This is the vapor specific enthalpy, which takes on temperature in K and vapor density in kg/m^3 and returns specific enthalpy in J/Kg.

- `real wetst_sv(real T, real rho)`

  This is the vapor specific entropy, which takes on temperature in K and vapor density in kg/m^3 and returns specific entropy in J/Kg/K.

- `real wetst_muv(real T, real rho)`

  This is the vapor dynamic viscosity, which takes on temperature in K and vapor density in kg/m^3 and returns viscosity in kg/m/s.

- `real wetst_ktv(real T, real rho)`

  This is the vapor thermal conductivity, which takes on temperature in K and vapor density in kg/m^3 and returns thermal conductivity in W/m/K.

- `real wetst_rhol(real T)`

  This is the saturated liquid density, which takes on temperature in K and returns liquid density in kg/m^3.

- `real wetst_cpl(real T)`

  This is the saturated liquid specific heat at constant pressure, which takes on temperature in K and returns liquid specific heat in J/kg/K.

- `real wetst_mul(real T)`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This is the liquid dynamic viscosity, which takes on Temperature in K and returns dynamic viscosity in kg/m/s.

- `real wetst_ktl(real T)`

  This is the liquid thermal conductivity, which takes on temperature in K and returns thermal conductivity in W/m/K.

- `real wetst_surft(real T)`

  This is the liquid surface tension, which takes on Temperature in K and returns surface tension N/m.

At the end of the code you must define a structure of type `WS_Functions` whose members are pointers to the principle functions listed previously. The structure is of type `WS_Functions` and its name is `WetSteamFunctionList`.

```
UDF_EXPORT  WS_Functions  WetSteamFunctionList  =
 {
     wetst_init,     /*initialization  function*/
     wetst_satP,     /*Saturation  pressure*/
     wetst_satT,     /*Saturation  temperature*/
     wetst_eosP,     /*equation  of  state*/
     wetst_eosRHO,   /*equation  of  state*/
     wetst_hv,       /*vapor  enthalpy*/
     wetst_sv,       /*vapor  entropy*/
     wetst_cpv,      /*vapor  isobaric  specific  heat*/
     wetst_cvv,      /*vapor  isochoric  specific  heat*/
     wetst_muv,      /*vapor  dynamic  viscosity*/
     wetst_ktv,      /*vapor  thermal  conductivity*/
     wetst_rhol,     /*sat.  liquid  density*/
     wetst_cpl,      /*sat.  liquid  specific  heat*/
     wetst_mul,      /*sat.  liquid  viscosity*/
     wetst_ktl,      /*sat.  liquid  thermal  conductivity*/
     wetst_surft     /*liquid  surface  tension*/
 };
```

24.6.3. Compiling Your UDWSPF and Building a Shared Library File

This section presents the steps you will need to follow to compile your UDWSPF C code and build a shared library file. This process requires the use of a C compiler. For more details on compiler requirements, see Compilers in the *Fluent Customization Manual*.

Important

To use the UDWSPF you will need to first build the UDWSPF library by compiling your UDWSPF C code and then loading the library into the ANSYS Fluent code.

The UDWSPF shared library is built in the same way that the ANSYS Fluent executable itself is built. Internally, a script called `Makefile` is used to invoke the system C compiler to build an object code library that contains the native machine language translation of your higher-level C source code. This shared library is then loaded into ANSYS Fluent (either at run time or automatically when a case file is read) by a process called *dynamic loading*. The object libraries are specific to the computer architecture being used, as well as to the particular version of the ANSYS Fluent executable being run. The libraries must, therefore, be rebuilt any time ANSYS Fluent is upgraded, when the computer's operating system level changes, or when the job is run on a different type of computer.

The general procedure for compiling UDWSPF C code is as follows:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. Place the UDWSPF C code in your working directory (that is, where your case file resides).
2. Launch ANSYS Fluent.
3. Read your case file into ANSYS Fluent.
4. You can now compile your UDWSPF C code and build a shared library file using the commands provided in the text command interface (TUI):
   a. Select the `define/models/multiphase/wet-steam` menu item.

      `define` → `models` → `multiphase` → `wet-steam`

      If the Wet Steam model has not been enabled yet, use the following TUI commands to enable it:

      ```
      define/models/multiphase/wet-steam> enable?

      Enable wet steam model? [no] yes
      ```

   b. Select the `compile-user-defined-wetsteam-functions` option.
   c. Enter the compiled UDWSPF library name.

      The name given here is the name of the directory where the shared library (for example, `libudf`) will reside. For example, if you press **Enter** then a directory should exist with the name `libudf`, and this directory will contain library file called `libudf`. If, however, you type a new library name such as `mywetsteam`, then a directory called `mywetsteam` will be created and it will contain the library `libudf`.
   d. Continue on with the procedure when prompted.
   e. Enter the C source file names.

      Important

      Ideally you should place all of your functions into a single file. However, you can split them into separate files if desired.

   f. Enter the header file names, if applicable. If you do not have an extra header file, then press **Enter** when prompted.

      ANSYS Fluent will then start compiling the UDWSPF C code and put it in the appropriate architecture directory.

24.6.4. Loading the UDWSPF Shared Library File

To load the UDWSPF library, perform the following steps:

- Go to the `define/models/multiphase/wet-steam` menu item in the text user interface.

  `define` → `models` → `multiphase` → `wet-steam`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Select the `load-unload-user-defined-wetsteam-library` option and follow the procedure when prompted.

  If the loading of the UDWSPF library is successful, you will see a message similar to the following:

```
Opening user-defined wet steam library "libudf"...
Library "libudf/lnamd64/2d/libudf.so" opened

Setting material properties to Wet-Steam...

Initializing user defined material properties...
```

24.6.5. UDWSPF Example

This section describe a simple UDWSPF. You can use this example as the basis for your own UDWSPF code. For approximate calculations at low pressure, the simple ideal-gas equation of state and constant isobaric specific heat is assumed and used. The properties at the saturated liquid line and the saturated vapor line used in this example are similar to the one used by ANSYS Fluent.

```

24.7. Solution Strategies for Multiphase Modeling

Important

Double Precision is recommended for all multiphase cases.

For additional information, see the following sections:

24.7.1. Coupled Solution for Eulerian Multiphase Flows
24.7.2. Coupled Solution for VOF and Mixture Multiphase Flows
24.7.3. Selecting the Pressure-Velocity Coupling Method
24.7.4. Controlling the Volume Fraction Coupled Solution
24.7.5. VOF Model
24.7.6. Mixture Model
24.7.7. Eulerian Model
24.7.8. Wet Steam Model

24.7.1. Coupled Solution for Eulerian Multiphase Flows

In multiphase flow, the phasic momentum equations, the shared pressure, and the phasic volume fraction equations are highly coupled. Traditionally, these equations have been solved in a segregated fashion using some variation of the SIMPLE algorithm to couple the shared pressure with the momentum

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

equations. This is attained by effectively transforming the total continuity into a shared pressure. The ANSYS Fluent **Phase Coupled SIMPLE** algorithm has been successfully implemented and solves a wide range of multiphase flows. However, coupling the linearized system of equations in an implicit manner would offer a more robust alternative to the segregated approach.

One of the fundamental problems is that the resulting matrix is not symmetric and that the continuity constraint may contribute to a zero diagonal block, making the solution difficult to obtain. One way to circumvent this problem is to use direct solvers, but these are too expensive for large industrial cases. In addition, we need to avoid a zero diagonal, resulting from the continuity constraint, and like the segregated solver, we need to construct a pressure correction equation. In multiphase, we also have the additional problem of the vanishing phase, which for the coupled solver is important to ensure some continuity in the coefficients. Like the **Phase Coupled**, we use a Rhie and Chow type of scheme to calculate volume fluxes and to provide proper coupling between velocity and pressure, thereby avoiding unphysical oscillations.

Consider a single-phase system and let us denote the velocity correction components in the three Cartesian directions by u', v', and w' with p' denoting the shared pressure correction. These are discrete variables and can be expressed in the form p', U'. The linear system that is generated by the single-phase coupled solver is of the form

$$\begin{pmatrix} A_p & C_U \\ B_U & A_U \end{pmatrix} \begin{pmatrix} p' \\ U' \end{pmatrix} = \begin{pmatrix} S_p \\ S_U \end{pmatrix} \tag{24.16}$$

For a notation in component form $\left(p', u', v', w'\right)$

$$\begin{pmatrix} A_{pp} & C_u & C_v & C_w \\ B_u & A_{uu} & A_{uv} & A_{uw} \\ B_v & A_{vu} & A_{vv} & A_{vw} \\ B_w & A_{wu} & A_{wv} & A_{ww} \end{pmatrix} \begin{pmatrix} p' \\ u' \\ v' \\ w' \end{pmatrix} = \begin{pmatrix} S_p \\ S_u \\ S_v \\ S_w \end{pmatrix} \tag{24.17}$$

Now let us consider a multiphase system of n-phases and denote the phasic velocity correction components in the three Cartesian directions by u_k', v_k', and w_k' where the subscript k represents the phase notation, p' denotes the shared pressure correction and α_k' denotes the volume fraction correction (ANSYS Fluent can solve in both correction form for velocity and volume fraction and non-correction form). For simplicity the matrix will be shown for two phases. The vector solution is of the form $\left(p', u_1', v_1', w_1', u_2', v_2', w_2', \alpha_2'\right)$ or in a shorter notation $\left(p', U_1', U_2', \alpha_2'\right)$. The linear system would be an extension of the one generated by the coupled solver shown by Equation 24.16 (p. 1505).

$$\begin{pmatrix} A_p & C_{U1} & C_{U2} & D_{\alpha 2} \\ B_{U1} & A_{U1} & A_{U12} & D_{U1} \\ B_{U2} & A_{U21} & A_{U2} & D_{U2} \\ E_p & E_{U1} & E_{U2} & A_{\alpha 2} \end{pmatrix} \begin{pmatrix} p' \\ U_1' \\ U_2' \\ \alpha_2' \end{pmatrix} = \begin{pmatrix} S_p \\ S_{U1} \\ S_{U2} \\ S_{\alpha 2} \end{pmatrix} \tag{24.18}$$

This system can be easily generalized to n phases. The components of this matrix are also matrices.

For large problems we need to resort to iterative solvers. The ANSYS Fluent AMG Coupled solver with an ILU smoother has proved to be a robust method. Most coupled solvers also need a pseudo stepping method, adding more diagonal dominance to the matrix. Our method here is to use under-relaxation factors for momentum, which is equivalent to time stepping in steady flows. Similar to that of the single phase, we have introduced a steady Courant Number instead of an under-relaxation for velocities. Having this control is important when using second order numerical schemes in the convective terms.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For the sake of simplicity, input parameters for the **Coupled** solver are similar to the single-phase solver. We have the options for solving the whole system including volume fraction, or to treat the volume fraction solution in a segregated manner while preserving the pressure-velocity coupling for all phases.

Important

Equations in multiphase are more strongly linked than single phase and generally may need more under-relaxation, hence using the same values as single phase may not be ideal. A low Courant number would stabilize the solution.

See Selecting the Pressure-Velocity Coupling Method (p. 1507) for information about applying the various algorithms.

24.7.2. Coupled Solution for VOF and Mixture Multiphase Flows

We have the option of solving the multiphase system for VOF and mixture multiphase models in the following ways:

- Solving the continuity and momentum equations in a coupled manner (see Coupled Algorithm in the Theory Guide) and solving the volume fraction equation in a segregated manner.
- Solving the volume fraction equation in a coupled manner along with the continuity and momentum equations.

Solving the volume fraction equation in a coupled manner requires discretization of the volume fraction equation in the correction form along with the discretization of the continuity and momentum equation, as discussed in Coupled Algorithm in the Theory Guide.

The volume fraction equation could be represented in the discretized form as

$$\sum_k \sum_j a_{ij}^{\alpha u_k} u_{kj} + \sum_j a_{ij}^{\alpha p} p_j + \sum_j a_{ij}^{\alpha\alpha} \alpha_j = b_i^{\alpha} \tag{24.19}$$

The overall system of equations after being transformed to the correction form could be represented as

$$\sum_j [A]_{ij} \vec{X}_j = \vec{B}_i \tag{24.20}$$

For a 2D case and two-phase flow, the system could be expanded as follows:

$$A_{ij} = \begin{bmatrix} a_{ij}^{pp} & a_{ij}^{pu} & a_{ij}^{pv} & a_{ij}^{p\alpha} \\ a_{ij}^{up} & a_{ij}^{uu} & a_{ij}^{uv} & a_{ij}^{u\alpha} \\ a_{ij}^{vp} & a_{ij}^{vu} & a_{ij}^{vv} & a_{ij}^{v\alpha} \\ a_{ij}^{\alpha p} & a_{ij}^{\alpha u} & a_{ij}^{\alpha v} & a_{ij}^{\alpha\alpha} \end{bmatrix} \tag{24.21}$$

and the unknown and residual vectors have the form

$$\vec{X}_j = \begin{bmatrix} p'_i \\ u'_i \\ v'_i \\ \alpha'_i \end{bmatrix} \tag{24.22}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$\vec{B}_i = \begin{bmatrix} -r_i^p \\ -r_i^u \\ -r_i^v \\ -r_i^\alpha \end{bmatrix} \tag{24.23}$$

where

A_{ij} = coefficient matrix

$\vec{X}_j$ = solution vector

$\vec{B}_i$ = residual vector

p' = pressure correction

u', v' = velocity corrections

α' = volume fraction correction

24.7.3. Selecting the Pressure-Velocity Coupling Method

The settings that are available in the **Solution Methods** task page (see Figure 24.64: The Solution Methods Task Page Displaying The Pressure-Velocity Coupling Options (p. 1509)) for solving the coupled system of equations arising in multiphase flows are:

Schemes

- **Phase Coupled SIMPLE** (Eulerian multiphase)
- **PISO** (VOF and mixture)
- **SIMPLE** (VOF and mixture)
- **SIMPLEC** (VOF and mixture)
- **Coupled** (all multiphase models)

Options

- **Coupled with Volume Fractions** (all multiphase models except drift-flux)
- **Solve N-Phase Volume Fraction Equations** (mixture and Eulerian models)

The **PISO**, **SIMPLE**, and **SIMPLEC** schemes apply to the VOF and mixture models and are discussed in Pressure-Velocity Coupling in the Theory Guide.

The **Phase Coupled SIMPLE** (PC-SIMPLE) is an extension of the SIMPLE algorithm [80] (p. 2891) to multiphase flows. The velocities are solved coupled by phases in a segregated fashion. Fluxes are reconstructed at the faces of the control volume and then a pressure correction equation is built based on total continuity. The coefficients of the pressure correction equations come from the coupled per phase momentum equations. This method has proven to be robust and it is the only method available for all previous versions of ANSYS Fluent.

The **Coupled** scheme (also known as **Multiphase Coupled** in previous ANSYS Fluent versions) solves all equations for phase velocity corrections and shared pressure correction simultaneously [34] (p. 2888). These methods incorporate the lift forces and the mass transfer terms implicitly into the general matrix.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

This method works very efficiently in steady-state situations, or for transient problems when larger time steps are required.

The **Coupled with Volume Fractions** option (also known as **Full Multiphase Coupled** in previous ANSYS Fluent versions) couples velocity corrections, shared pressure corrections, and the correction for volume fraction simultaneously. Theoretically, it should be more efficient, however it may have some drawbacks in robustness and CPU time usage. The robustness issue stems from the lack of control of the solution of the volume fraction equation. The continuity constraint (sum of all volume fractions equals 1, and individual values limited between zero and one) cannot be enforced exactly during inner solver iterations, and slight variations from the physical limits may lead to divergence. Research is on-going in this area to improve the method. The method is advantageous for heterogeneous mass transfer when a low Courant number is given; it also works well in dilute situations.

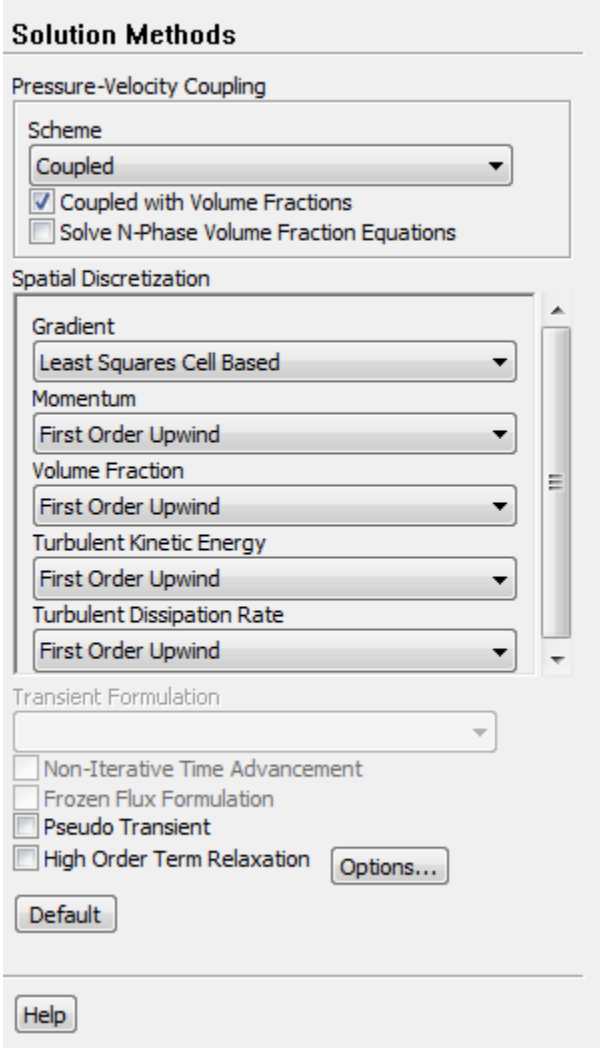
The Volume Fraction Coupling Method aims to achieve a faster steady-state solution compared to the segregated method of solving equations. It may not be a suitable option for transient applications due to the significant overhead in CPU time compared to the segregated method, unless it is run with a larger time step size.

Note

The **Coupled with Volume Fractions** option is available in the interface after you have selected **Coupled** from the **Scheme** drop-down list for **Pressure-Velocity Coupling**. For steady-state cases, the **Pseudo Transient** option will be enabled automatically when you enable the **Coupled with Volume Fractions** option for the VOF and mixture models.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.64: The Solution Methods Task Page Displaying The Pressure-Velocity Coupling Options



24.7.3.1. Limitations and Recommendations of the Coupled with Volume Fraction Options for the VOF and Mixture Models

The coupled with volume fractions option has the following limitations:

- It is not available when **Slip Velocity** is enabled for the **Mixture** multiphase model.
- It is not supported when using the Singhal-Et-Al cavitation model.
- It is not supported when the **Explicit** formulation for volume fraction is selected.

Recommended uses of the coupled with volume fractions option:

- The Pseudo-transient solver is recommended for steady-state calculations.
- It is recommended that you use lower under-relaxation factors for momentum for higher order schemes.
- For marine applications, it is recommended that you use a low-order variant or hybrid treatment for the Rhie-chow face flux interpolation (see High-Order Rhie-Chow Face Flux Interpolation (p. 1514)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- It is recommended that you use the expert text command options `solve/set/coupled-vof-expert` for better stability when using the VOF model (see `solve/` in the Text Command List).

24.7.3.2. Solving N-Phase Volume Fraction Equations

For a multiphase flow, the sum of the phase volume fractions must always equal 1. By default, Fluent enforces this constraint by solving the volume fraction equations for each of the secondary phases and then setting the volume fraction of the primary phase to the complement.

In certain cases, where poor convergence and/or mass imbalance are observed, enabling **Solve N-Phase Volume Fraction Equations** may improve solutions, although in practice the results obtained from using this option are case dependent. If selected, this option will solve all volume fraction equations, including both primary and secondary phases. The resulting phase volume fractions are then scaled in order to satisfy the requirement of summing to 1. This approach is more computationally expensive than the default approach and, in general, should not be necessary for the simulation.

Note

The **Solve N-Phase Volume Fraction Equations** option is not available for the **Volume of Fluid** model or **Eulerian** with **Multi-Fluid VOF Model** enabled.

24.7.4. Controlling the Volume Fraction Coupled Solution

When using the **Coupled with Volume Fractions** scheme, you will need to specify the following in the **Solution Controls** task page (see Figure 24.65: The Solution Controls Task Page Displaying the Coupled Volume Fraction Method for the VOF and Mixture Models (p. 1511)):

- **VOF and Mixture Multiphase Model:**
  - For steady-state cases using the pseudo transient solver, specify the **Volume Fraction Courant Number**, and the **Pseudo Transient Explicit Relaxation Factors**. The **Pseudo Transient Explicit Relaxation Factors** are described in Setting Pseudo Transient Explicit Relaxation Factors (p. 1602).

    Note

    The **Pseudo Transient Explicit Relaxation Factors** for the **Volume Fraction** is set to 0.5 by default.

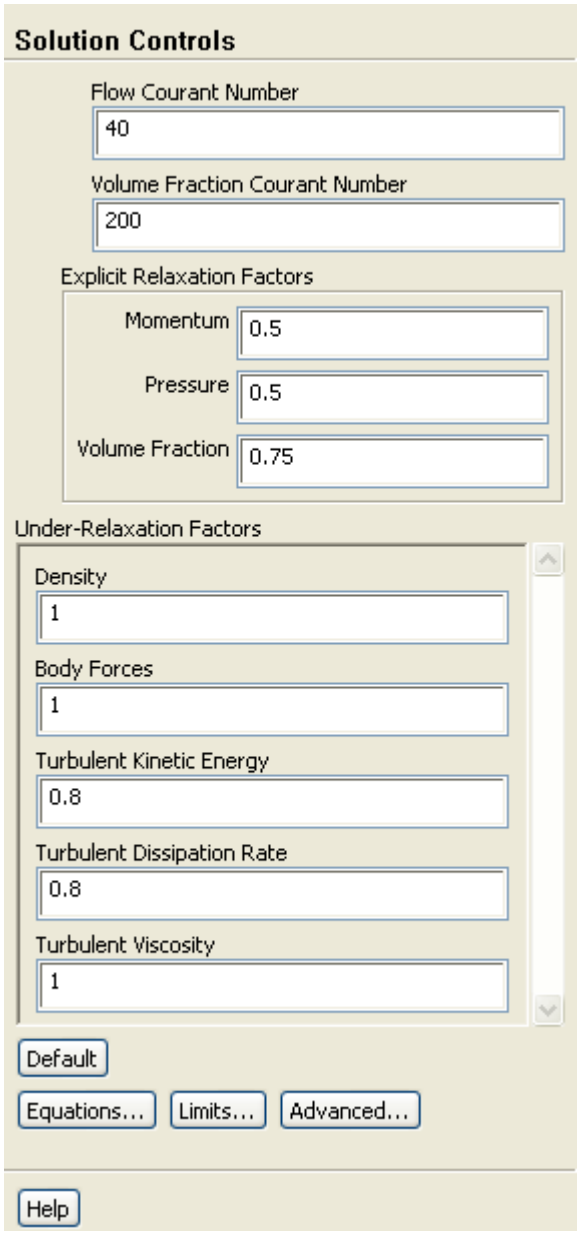
  - For transient cases or steady-state cases not involving the pseudo transient solver, enter the **Flow Courant Number**, the **Volume Fraction Courant Number**, **Explicit Relaxation Factors**, and the **Under-Relaxation Factors**.

    Note

    The **Volume Fraction** is set as an **Explicit Relaxation Factor** and is 0.75 by default.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 24.65: The Solution Controls Task Page Displaying the Coupled Volume Fraction Method for the VOF and Mixture Models



- **Eulerian Multiphase Model:**

  – For steady-state cases using the pseudo transient solver, specify the **Pseudo Transient Explicit Relaxation Factors** as described in Setting Pseudo Transient Explicit Relaxation Factors (p. 1602).

  Note

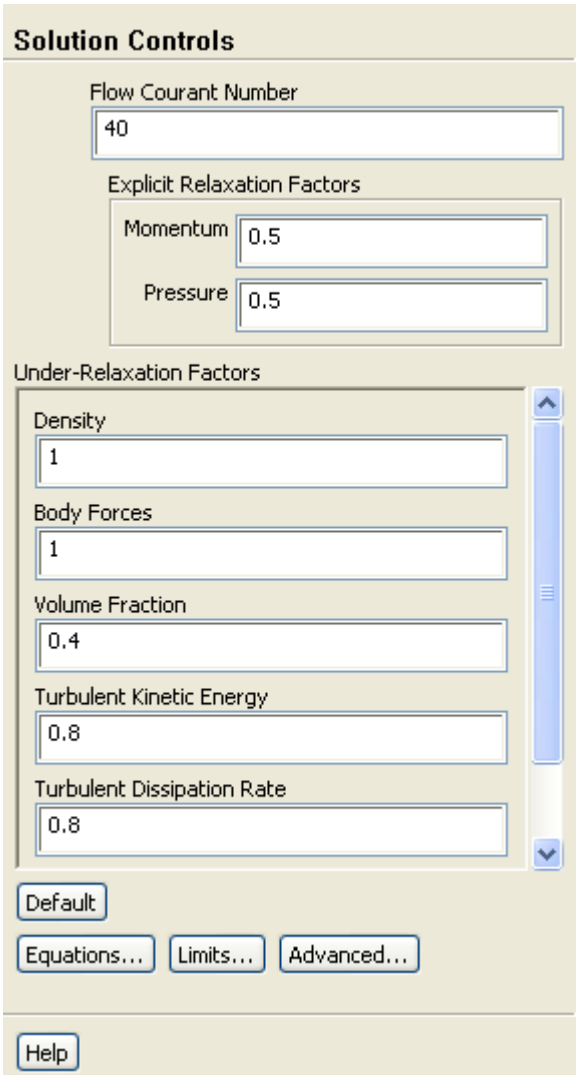
  The **Pseudo Transient Explicit Relaxation Factors** for the **Volume Fraction** is set to 0.5 by default.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

– For transient cases or steady-state cases not involving the pseudo transient solver, enter the **Flow Courant Number**, the **Explicit Relaxation Factors**, and the **Under-Relaxation Factors**.

> **Note**
>
> The under-relaxation for **Volume Fraction** is set by using an implicit **Under-Relaxation Factor**, rather than a **Volume Fraction Courant Number**, and is 0.5 by default.

Figure 24.66: The Solution Controls Task Page Displaying the Coupled Volume Fraction Method for the Eulerian Multiphase Model



24.7.5. VOF Model

Several recommendations for improving the accuracy and convergence of the VOF solution are presented here.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.7.5.1. Setting the Reference Pressure Location

The site of the reference pressure can be moved to a location that will result in less round-off in the pressure calculation. By default, the reference pressure location is the center of the cell at or closest to the point (0,0,0). You can move this location by specifying a new **Reference Pressure Location** in the Operating Conditions Dialog Box (p. 2382).

Setup → Cell Zone Conditions → Operating Conditions...

The position that you choose should be in a region that will always contain the least dense of the fluids (for example, the gas phase, if you have a gas phase and one or more liquid phases). This is because variations in the static pressure are larger in a more dense fluid than in a less dense fluid, given the same velocity distribution. If the zero of the relative pressure field is in a region where the pressure variations are small, less round-off will occur than if the variations occur in a field of large nonzero values. Thus in systems containing air and water, for example, it is important that the reference pressure location be in the portion of the domain filled with air rather than that filled with water.

24.7.5.2. Pressure Interpolation Scheme

For all VOF calculations, you should use the body-force-weighted pressure interpolation scheme or the PRESTO! scheme.

Solution → Controls

24.7.5.3. Discretization Scheme Selection

The availability of discretization schemes for volume fraction is summarized in Spatial Discretization Schemes for Volume Fraction (p. 1373).

If you are modeling a sharp interface regime on meshes that have high aspect ratio cells, large jumps in cell size, or high skewness, interface capturing schemes such as **Compressive** and **CICSAM** will not produce very sharp results. For such cases, you should use the **Geo-Reconstruct** scheme.

For meshes of good quality, it is recommended that you use the **Compressive** scheme, which is available in both explicit and implicit formulations and is applicable to both sharp and dispersed flow regimes. The **Compressive** scheme also provides better accuracy compared with **CICSAM** and **Modified HRIC** for most cases. When used with the implicit formulation and the second order time scheme, the **Compressive** scheme produces quite a sharp interface.

When using the **Compressive** spatial discretization scheme, it is recommended that you use step-wise sharpening after the flow transitions from the diffused zone to the sharpening zone. In other words, you would want to transition from first order to second order, followed by a transition from second order to compressive. You would want to take this approach if the flow has a smooth transition from a sharp interfacial zone to a diffused interfacial zone. However, if the flow has a nonuniform transition from a diffused interfacial zone to a sharp interfacial zone, this might create unphysical sharpening of the interface if not handled properly, especially for transient cases. For example, transitioning from a slope limiter of 2 (compressive) to a slope limiter of 0 or 1 (first order or second order) might be acceptable, but a first order to compressive transition might create unphysical sharpening of the interface.

If you are solving a problem with the **evaporation-condensation** mass transfer mechanism enabled (Including Mass Transfer Effects (p. 1383)) it is recommended that you use one of the diffusive interface

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

capturing schemes such as **QUICK**, **HRIC**, or **Phase Localized Compressive** (Discretizing Using the Phase Localized Compressive Scheme (p. 1443)).

Important

The **BGM** scheme produces a sharp interface, which may result in poor convergence in some cases. In such situations, we recommend you use a low value for the VOF under-relaxation. In addition, you can start with the **Compressive** or **Modified HRIC** scheme and then switch to the **BGM** scheme.

24.7.5.4. High-Order Rhie-Chow Face Flux Interpolation

In VOF modeling, using a high-order discretization scheme for the momentum transport equations may reduce the stability of the solution compared to cases using first-order discretization. In such situations, there are a couple of recommendations:

1. Use a low-order variant of the Rhie-Chow face flux interpolation. This is enabled using the following text command:

   `solve` → `set` → `numerics`

   You will be asked

   ```
   disable high order Rhie-Chow flux? [no]
   ```

   to which you will respond `yes`.

2. Use a hybrid treatment of high-order Rhie-Chow face flux interpolation. This is enabled using the following text command:

   `solve` → `set` → `vof-numerics`

   You will be asked

   ```
   Use hybrid treatment for high order Rhie-Chow flux?  [no]
   ```

   to which you will respond `yes`.

   Hybrid treatment allows you to use a high-order variant of the Rhie-Chow face flux interpolation everywhere inside the domain, except in the vicinity of the interface where a low-order variant is used for the interpolation of the face flux. This treatment could be helpful to get better convergence without compromising much of the accuracy.

24.7.5.5. Treatment of Unsteady Terms in Rhie-Chow Face Flux Interpolation

For cases using Moving Mesh/Dynamic Mesh/Multiple Reference Frame models, ANSYS Fluent does not consider the unsteady terms for Rhie-Chow face flux interpolation by default. Accounting for the unsteady terms helps to achieve better solution stability, especially when using a lower time step size with the PRESTO scheme.

To enable forced treatment of unsteady terms in Rhie-Chow face flux interpolation, use the following text command:

`solve` → `set` → `vof-numerics`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You will be asked

```
Use forced treatment of unsteady terms in Rhie-Chow flux? [no]
```

to which you will respond yes.

24.7.5.6. Using Unstructured Variant of PRESTO Pressure Scheme

For hexahedral and quadrilateral meshes, ANSYS Fluent uses the structured variant of the PRESTO scheme by default. For certain cases with non-conformal grid interfaces, the structured variant produces unexpected behavior at the intersection of the fluid-fluid and non-conformal grid interfaces. For these cases, using an unstructured variant of PRESTO provides better solution stability and avoids unexpectedly high velocities in the vicinity of the non-conformal grid interfaces.

To enable the unstructured variant of the PRESTO scheme, use the following text command:

`solve` → `set` → `vof-numerics`

You will be asked

```
Use unstructured variant of PRESTO pressure scheme? [no]
```

to which you will respond yes.

Note

The unstructured variant of PRESTO is automatically enabled for cases involving an unstructured mesh and this option is redundant in its usage.

24.7.5.7. Pressure-Velocity Coupling and Under-Relaxation for the Time-dependent Formulations

Another change that you should make to the solver settings is in the pressure-velocity coupling scheme and under-relaxation factors that you use. The PISO scheme is recommended for transient calculations in general. Using PISO allows for increased values on all under-relaxation factors, without a loss of solution stability. You can generally increase the under-relaxation factors for all variables to 1 and expect stability and a rapid rate of convergence (in the form of few iterations required per time step). For calculations on tetrahedral or triangular meshes, an under-relaxation factor of 0.7–0.8 for pressure is recommended for improved stability with the PISO scheme.

Solution → **Controls**

As with any ANSYS Fluent simulation, the under-relaxation factors will need to be decreased if the solution exhibits unstable, divergent behavior with the under-relaxation factors set to 1. Reducing the time step is another way to improve the stability.

24.7.5.8. Under-Relaxation for the Steady-State Formulation

If you are using the steady-state implicit VOF scheme, the under-relaxation factors for all variables should be set to values between 0.2 and 0.5 for improved stability.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.7.6. Mixture Model

24.7.6.1. Setting the Under-Relaxation Factor for the Slip Velocity

You should begin the mixture calculation with a low under-relaxation factor for the slip velocity. A value of 0.2 or less is recommended. If the solution shows good convergence behavior, you can increase this value gradually.

24.7.6.2. Calculating an Initial Solution

For some cases (for example, cyclone separation), you may be able to obtain a solution more quickly if you compute an initial solution without solving the volume fraction and slip velocity equations. Once you have set up the mixture model, you can temporarily disable these equations and compute an initial solution.

Solution → **Controls**

In the Equations Dialog Box (p. 2511), deselect **Volume Fraction** and **Slip Velocity** in the **Equations** list. You can then compute the initial flow field. Once a converged flow field is obtained, turn the **Volume Fraction** and **Slip Velocity** equations back on again, and compute the mixture solution.

24.7.7. Eulerian Model

24.7.7.1. Calculating an Initial Solution

To improve convergence behavior, you may want to compute an initial solution before solving the complete Eulerian multiphase model. There are multiple methods you can use to obtain an initial solution for an Eulerian multiphase calculation:

- Set up and solve the problem using the mixture model (with slip velocities) instead of the Eulerian model. You can then enable the Eulerian model, complete the setup, and continue the calculation using the mixture-model solution as a starting point.
- Set up the Eulerian multiphase calculation as usual, but compute the flow for only the primary phase. To do this, deselect **Volume Fraction** in the **Equations** list in the Equations Dialog Box (p. 2511). Once you have obtained an initial solution for the primary phase, turn the volume fraction equations back on and continue the calculation for all phases.
- Use the mass flow inlet boundary condition to initialize the flow conditions. It is recommended that you set the value of the volume fraction close to the value of the volume fraction at the inlet.
- At the beginning of the solution, a lower time step is recommended in order to reach convergence.
- If using the volume fraction explicit scheme, do not start with a large Courant number at the beginning of your run.
- If using the volume fraction explicit scheme, start a run with a lower time step and then increase the time step size. Alternatively, this could be done by using variable time stepping, which would increase the time step size based on the input parameters.
- For problems involving a free surface or sharp interfaces between the phases, it is recommended that you use the **symmetric** drag law, available in the Phase Interaction Dialog Box (p. 2363).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Variable time stepping is not recommended for compressible flows.

Important

You should *not* try to use a single-phase solution obtained without the mixture or Eulerian model as a starting point for an Eulerian multiphase calculation. Doing so will not improve convergence, and may make it even more difficult for the flow to converge.

24.7.7.2. Temporarily Ignoring Lift and Virtual Mass Forces

If you are planning to include the effects of lift and/or virtual mass forces in a steady-state Eulerian multiphase simulation, you can often reduce stability problems that sometimes occur in the early stages of the calculation by temporarily ignoring the action of the lift and the virtual mass forces. Once the solution without these forces starts to converge, you can interrupt the calculation, define these forces appropriately, and continue the calculation.

24.7.7.3. Using W-Cycle Multigrid

For problems involving a packed-bed granular phase with very small particle sizes (on the order of 10 μm), convergence can be obtained by using the W-cycle multigrid for the pressure. In the **Multigrid** tab, under **Fixed Cycle Parameters** in the Advanced Solution Controls Dialog Box (p. 2513), you may need to use higher values for **Pre-Sweeps**, **Post-Sweeps**, and **Max Cycles**. When you are choosing the values for these parameters, you should also increase the **Verbosity** to `1` in order to monitor the AMG performance; that is, to make sure that the pressure equation is solved to a desired level of convergence within the AMG solver during each global iteration. See Defining the Phases for the Eulerian Model (p. 1456) for more information about granular phases, and The V and W Cycles in the Theory Guide and Modifying Algebraic Multigrid Parameters (p. 1670) for details about multigrid cycles.

24.7.7.4. Including the Anisotropic Drag Law

When using the anisotropic drag law (Including the Multi-Fluid VOF Model (p. 1493)), it is recommended that you start the solution with a lower anisotropy ratio. After your solution has run for some time, you can then increase the ratio by reducing the friction factor in the tangential direction. Note that You can also start the solution with the symmetric drag law, then change to the anisotropic drag law.

Using a smaller under-relaxation for pressure and momentum may also help in convergence for cases with a higher anisotropy ratio.

If the flow for a particular phase is important in both directions (normal and tangential to the interface), use a lower anisotropy ratio, between 100-1000. A higher anisotropy ratio might cause an unstable solution for such cases. For a higher anisotropy ratio of more than 1000, a smaller under-relaxation for pressure and momentum is recommended. When using the coupled multiphase solver, if the solution is unstable with a higher anisotropy ratio, then reducing the courant number may be beneficial. `Anisotropic Drag Method` [1], with `Viscosity option` [2] is recommended for a higher viscosity ratio.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.7.8. Wet Steam Model

24.7.8.1. Boundary Conditions, Initialization, and Patching

When you use the wet steam model (described in Wet Steam Model Theory in the Theory Guide, and Setting Up the Wet Steam Model (p. 1495)), the following two field variables will show up in the inflow, outflow boundary dialog boxes, and in the **Solution Initialization** task page and **Patch** dialog boxes.

- **Liquid Mass Fraction** (or the wetness factor)

  In general, for dry steam entering flow boundaries the wetness factor is zero.

- **Log10 (Droplets Per Unit Volume)**

  In general this value is set to zero, indicating zero droplets entering the domain.

24.7.8.2. Solution Limits for the Wet Steam Model

When you select the wet steam model for the first time, a message is displayed indicating that the **Minimum Static Temperature** should be adjusted to 273 K since the accuracy of the built-in steam data is not guaranteed below a value of 273 K. If you use your own steam property functions, you can adjust this limit to whatever is permissible for your data.

To adjust the temperature limits, go to the **Solution Limits** dialog box.

Solution → **Controls** **Limits...**

The default maximum wetness factor or liquid mass fraction (β) is set to 0.1. In general, during the convergence process, it is common that this limit will be reached, but eventually the wetness factor will drop below the value of 0.1. However, in cases where the limit must be adjusted, you can do so using the text user interface.

`define` → `models` → `multiphase` → `wet-steam` → `set` → `max-liquid-mass-fraction`

Important

Note that the maximum wetness factor should not be set beyond 0.2 since the present model assumes a low wetness factor. When the wetness factor is greater than 0.1, the solution tends to be less stable due to the large source terms in the transport equations. Thus, the maximum wetness factor has been set to a default value of 0.1, which corresponds to the fact that most nozzle and turbine flows will have a wetness factor less than 0.1.

24.7.8.3. Solution Strategies for the Wet Steam Model

If you face convergence difficulties while solving wet steam flow, try to initially lower the CFL value and use first-order discretization schemes for the solution. If you are still unable to obtain a converged solution, then try the following solver settings:

1. Lower the under-relaxation factor for the wet steam equation below the current set value. The under-relaxation factor can be found in the **Solution Controls** task page.

   Solution → **Controls**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

2. Solve for an initial solution with no condensation. Once you have obtained a proper initial solution, turn on the condensation.

   To turn condensation on or off, go to the **Solution Controls** task page.

   Solution → **Controls**

   In the **Equations** dialog box, deselect **Wet Steam** in the **Equations** list. When doing so, you are preventing condensation from taking place while still computing the flow based on steam properties. Once a converged flow field is obtained, turn the **Wet Steam** equation back on again and compute the mixture solution.

24.8. Multiphase Case Check

You can check the multiphase case setup using the multiphase check function available via the text user interface (TUI) command:

```
/report/mphase-summary
```

This function prints for you a summary of useful settings, important model information, and recommendations for choosing case parameters. Your case will be checked for compliance in the following categories:

- `MODELING`
- `MESHING`
- `PHASES`
- `PHASE INTERACTION`
- `BOUNDARY CONDITIONS`
- `CELL ZONE CONDITIONS`
- `OPERATING CONDITIONS`
- `SOLVER METHODS/CONTROLS`
- `ADVANCED SOLVER NUMERICS`
- `MULTIPHASE NUMERICS`
- `SOLUTION LIMITS`
- `MONITORS/RESIDUALS`
- `INITIALIZATION`
- `RUN CALCULATION`
- `POST PROCESSING`

Important

To execute this command, a case and valid data (solution or initialization) are required. If the case has been modified, you need to either reinitialize or rerun the case.

When prompted for `verbosity`, you can set the level of detail for the report. A value of **`0`** (the default) corresponds to a basic report, while a value of **`1`** corresponds to a more detailed report.

In each category, established rules and built-in best practices will be available, along with recommended changes to your current settings. At your discretion, you may choose to apply the recommendations, or keep your current settings. Refer to the appropriate sections in the Fluent User's Guide for more information about the recommended changes.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

24.9. Postprocessing for Multiphase Modeling

Each of the three general multiphase models provides a number of additional field functions that you can plot or report. You can also report flow rates for individual phases for all three models, and display velocity vectors for the individual phases in a mixture or Eulerian calculation.

Information about these postprocessing topics is provided in the following subsections:

24.9.1. Model-Specific Variables
24.9.2. Displaying Velocity Vectors
24.9.3. Reporting Fluxes
24.9.4. Reporting Forces on Walls
24.9.5. Reporting Flow Rates

24.9.1. Model-Specific Variables

When you use one of the general multiphase models, some additional field functions will be available for postprocessing, as listed in this section. Most field functions that are available in single phase calculations will be available for either the mixture or each individual phase, as appropriate for the general multiphase model and specific options that you are using. See Field Function Definitions (p. 1931) for a complete list of field functions and their definitions. Displaying Graphics (p. 1747) and Reporting Alphanumeric Data (p. 1885) explain how to generate graphics displays and reports of data.

24.9.1.1. VOF Model

For VOF calculations you can generate graphical plots or alphanumeric reports of the following additional item:

- **Volume fraction** (in the **Phases...** category)

  This item is available for each phase.

The variables that are not phase specific are available (for example, variables in the **Pressure...** and **Velocity...** categories) and represent mixture quantities. Thermal quantities will be available only for calculations that include the energy equation.

24.9.1.2. Mixture Model

For calculations with the mixture model, you can generate graphical plots or alphanumeric reports of the following additional items:

- **Diameter** (in the **Properties...** category)

  This item is available only for secondary phases.

- **Volume fraction** (in the **Phases...** category)

  This item is available only for secondary phases.

- **Interfacial Area Concentration** (in the **Interfacial Area Concentration...** category)

  This item is available only for secondary phases.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

The variables that are not phase specific are available (for example, variables in the **Pressure...** category) represent mixture quantities. Thermal quantities will be available only for calculations that include the energy equation.

24.9.1.3. Eulerian Model

For Eulerian multiphase calculations you can generate graphical plots or alphanumeric reports of the following additional items:

- **Diameter** (in the **Properties...** category)

  This item is available only for secondary phases.

- **Granular Conductivity** (in the **Properties...** category)

  This item is available only for granular phases.

- **Granular Pressure** (in the **Granular Pressure...** category)

  This item is available only for granular phases.

- **Granular Temperature** (in the **Granular Temperature...** category)

  This item is available only for granular phases.

- **Volume fraction** (in the **Phases...** category)

  This item is available only for secondary phases.

- **Interfacial Area Concentration** (in the **Interfacial Area Concentration...** category)

  This item is available only for secondary phases.

The availability of turbulence quantities will depend on which multiphase turbulence model you used in the calculation. Thermal quantities will be available (on a per-phase basis) only for calculations that include the energy equation.

More advanced options for the mixture phase are available under the **Phases...** category, allowing you to select from a list of variables to postprocess. To access the entire list in the graphical user interface, type the following text command:

`solve` → `set` → `expert`

Retain most of the default settings, except when asked to `Keep temporary solver memory from being freed?`. Answering `yes` to this question will expose a list under the **Phases** category for the mixture phase, one of which will be the **Phase ID**. Selecting this option allows you to plot contours

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of phase IDs for the volume fraction, which will facilitate phase distribution display when more than two phases are present for free surface calculations.

Note

The `expert` option for not freeing temporary solver memory is incompatible with dynamic adaption in parallel.

Important

This option is available for all the multiphase models. However, note that only cell values should be plotted for this option. Make sure that the **Node Values** option is not selected as it will show the wrong phase ID contours at the interface.

24.9.1.4. Multiphase Species Transport

For calculations using species transport with either of the multiphase models, you can generate graphical plots or alphanumeric reports of the following additional items:

- **Mass Fraction of species-n** (in the **Species...** category)

  This item is available for each species.

- **Mole Fraction of species-n** (in the **Species...** category)

  This item is available for each species.

- **Molar Concentration of species-n** (in the **Species...** category)

  This item is available for each species.

- **Lam. Diff Coeff of species-n** (in the **Species...** category)

  This item is available for each species.

- **Eff. Diff. Coeff. of species-n** (in the **Species...** category)

  This item is available for each species.

- **Enthalpy of species-n** (in the **Species...** category)

  This item is available for each species.

- **Relative Humidity** (in the **Species...** category).

- **Turbulent Rate of Reaction-n** (in the **Reactions...** category)

  This item is available for each species.

- **Rate of Reaction** (in the **Reactions...** category).

- **Mass Transfer Rate n** (in the **Phase Interaction...** category)

  This item is available for each mass transfer mechanism that you defined.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Thermal quantities will be available only for calculations that include the energy equation.

24.9.1.5. Wet Steam Model

ANSYS Fluent provides a wide range of postprocessing information related to the wet steam model.

The wet steam related items can be found in **Wet Steam....** category of the variable selection drop-down list that appears in the postprocessing dialog boxes.

- **Liquid Mass Fraction**
- **Liquid Mass Generation Rate**
- **Log10 (Droplets Per Unit Volume)**
- **Log10 (Droplets Nucleation Rate)**
- **Steam Density (Gas-Phase)**
- **Liquid Density (Liquid-Phase)**
- **Mixture Density**
- **Saturation Ratio**
- **Saturation Pressure**
- **Saturation Temperature**
- **Subcooled Vapor Temperature**
- **Droplet Surface Tension**
- **Droplet Critical Radius (microns)**
- **Droplet Average Radius (microns)**
- **Droplet Growth Rate (microns/s)**

24.9.1.6. Dense Discrete Phase Model

For postprocessing, both the DPM and the Eulerian multiphase capabilities are retained. In addition to usual DPM postprocessing (Postprocessing for the Discrete Phase (p. 1329)), you can display, for example, vector plots of the particle's velocity field. Make sure to select the discrete phase from the **Phase** drop-down list. For transient simulations that include the dense discrete phase model, you can display the following when the **Unsteady Statistics...** category is selected:

- **Mean Velocity**
- **Mean Volume Fraction**
- **Mean Phase Diameter**
- **RMSE Velocity**
- **RMSE Volume Fraction**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **RMSE Phase Diameter**

Important

For the **Unsteady Statistics...** category to appear in the postprocessing dialog boxes, make sure that **Data Sampling for Time Statistics** is enabled in the **Run Calculation** task page, and that you have performed the calculation.

24.9.2. Displaying Velocity Vectors

For mixture and Eulerian calculations, it is possible to display velocity vectors for the individual phases using the **Vectors** dialog box.

Results → **Graphics** → **Vectors** **Edit...**

To display the velocity of a particular phase, select **Velocity** in the **Vectors of** drop-down list, and then select the desired phase in the **Phase** drop-down list. You can also choose **Relative Velocity** to display the phase velocity relative to a moving reference frame. To display the mixture velocity $\vec{v}_m$ (relevant for mixture model calculations only), select **Velocity** (or **Relative Velocity** for the mixture velocity relative to a moving reference frame), and **mixture** as the **Phase**. Note that you can color vectors by values of any available variable, for any phase you defined. To do so, make the appropriate selections in the **Color by** and following **Phase** drop-down lists.

24.9.3. Reporting Fluxes

When you use the **Flux Reports** dialog box to compute fluxes through boundaries, you will be able to specify whether the report is for the mixture or for an individual phase.

Results → **Reports** → **Fluxes** **Edit...**

Select **mixture** in the **Phase** drop-down list at the bottom of the dialog box to report fluxes for the mixture, or select the name of a phase to report fluxes just for that phase.

24.9.4. Reporting Forces on Walls

For Eulerian calculations, when you use the **Force Reports** dialog box to compute forces or moments on wall boundaries, you will be able to specify the individual phase for which you want to compute the forces.

Results → **Reports** → **Forces** **Edit...**

Select the name of the desired phase in the **Phase** drop-down list on the left side of the dialog box.

24.9.5. Reporting Flow Rates

You can obtain a report of mass flow rate for each phase (and the mixture) through each flow boundary using the `report/fluxes/mass-flow` text command:

`report` → `fluxes` → `mass-flow`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When you specify the phase of interest (the mixture or an individual phase), ANSYS Fluent will give you the option to list each zone, followed by a summary of the mass flow rate through that zone for the specified phase, or will summarize the mass flow rate for all zones. An example is shown below, demonstrating how to list the mass flow rate for all zones.

```
/report/fluxes> mf
(mixture water air)
domain id/name [mixture] air
all boundary/interior zones [yes]
Write to File? [no]

                            air
                  Mass Flow Rate               (kg/s)
------------------------------- --------------------
             spiral-press-outlet           -1.2330244
                 pressure-outlet           -9.7560663
                spiral-vel-inlet            0.6150589
                           walls                    0
                  velocity-inlet            4.9132133
                --------------- --------------------
                             Net           -5.4608185
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 25: Modeling Solidification and Melting

This chapter describes how you can model solidification and melting in ANSYS Fluent. For information about the theory behind the model, see Solidification and Melting in the Theory Guide. Information about using the model is organized into the following sections:

25.1. Setup Procedure
25.2. Procedures for Modeling Continuous Casting
25.3. Modeling Thermal and Solutal Buoyancy
25.4. Solution Procedure
25.5. Postprocessing

25.1. Setup Procedure

The procedure for setting up a solidification/melting problem is described below. (Note that this procedure includes only those steps necessary for the solidification/melting model itself; you will need to set up other models, boundary conditions, and so on, as usual.)

1. To use the solidification/melting model, enable the **Solidification/Melting** option in the **Solidification and Melting** dialog box (Figure 25.1: The Solidification and Melting Dialog Box (p. 1527)).

   Setup → **Models** → **Solidification & Melting** **Edit...**

   Figure 25.1: The Solidification and Melting Dialog Box

   
   ANSYS Fluent will automatically enable the energy equation, so you do not have to visit the **Energy** dialog box before turning on the solidification/melting model.

2. Under **Parameters**, specify the value of the **Mushy Zone Parameter** (A_{mush} in Equation 18.6) as a **constant**, or as a **user-defined** function. Refer to `DEFINE_SOLIDIFICATION_PARAMS` in the Fluent Customization Manual for detailed information about the user-defined function.

Values between 10^4 and 10^7 are recommended for most computations. The higher the value of the **Mushy Zone Parameter**, the steeper the damping curve becomes, and the faster the velocity drops to zero as the material solidifies. Very large values may cause the solution to oscillate as control volumes alternately solidify and melt with minor perturbations in liquid volume fraction.

3. If you want to include the pull velocity in your simulation (as described in Momentum Equations and Pull Velocity for Continuous Casting in the Theory Guide), enable the **Include Pull Velocities** option under **Parameters**.

4. If you are including pull velocities and you want ANSYS Fluent to compute them (using Equation 18.22) based on the specified velocity boundary conditions, as described in Pull Velocity for Continuous Casting in the Theory Guide, enable the **Compute Pull Velocities** option and specify the number of **Flow Iterations Per Pull Velocity Iteration**.

   Important

   It is not necessary to have ANSYS Fluent compute the pull velocities. See Procedures for Modeling Continuous Casting (p. 1530) for information about other approaches.

   The default value of 1 for the **Flow Iterations Per Pull Velocity Iteration** indicates that the pull velocity equations will be solved after each iteration of the solver. If you increase this value, the pull velocity equations will be solved less frequently. You may want to increase the number of **Flow Iterations Per Pull Velocity Iteration** if the liquid fraction equation is almost converged (that is, the position of the liquid-solid interface is not changing very much). This will speed up the calculation, although the residuals may jump when the pull velocities are updated.

5. Under **Options**, select either **Lever Rule** or **Scheil Rule**. See Species Equations in the Theory Guide for details.

   Important

   The **Lever Rule** and **Scheil Rule** options are available only when **Species Transport** is enabled in the **Species Model** dialog box.

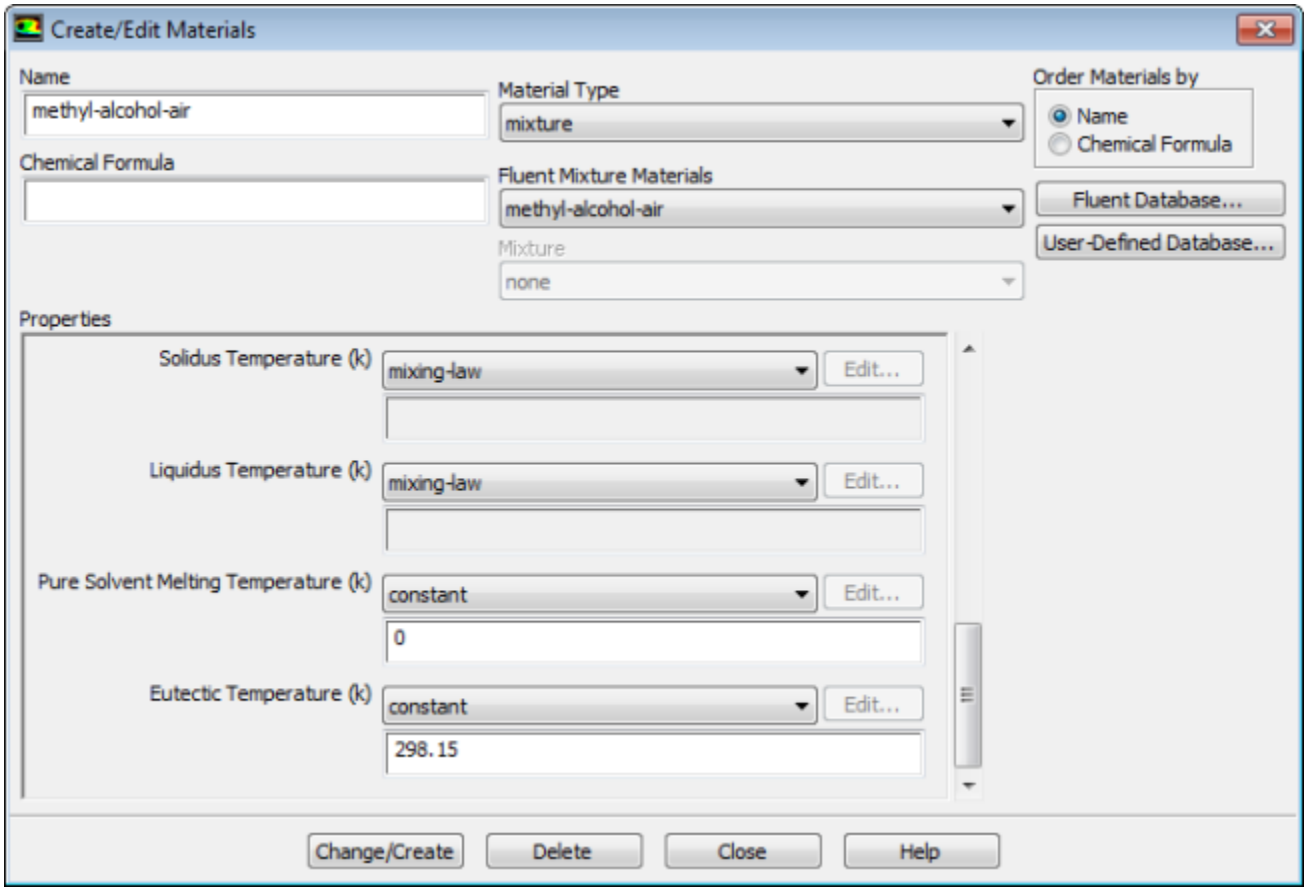
6. If you select **Scheil Rule**, then you can enable **Back Diffusion**. Enter either a **constant** or a **user-defined** function to specify the value of the **Back Diffusion Parameter** (γ in Equation 18.19). Refer to `DEFINE_SOLIDIFICATION_PARAMS` in the Fluent Customization Manual for detailed information about the user-defined function. Note that the value for the **Back Diffusion Parameter** must be between 0 and 1.

7. In the Create/Edit Materials Dialog Box (p. 2302) (Figure 25.2: The Create/Edit Materials Dialog Box for Melting and Solidification (p. 1529)), specify the **Pure Solvent Melting Heat** (L in Equation 18.4), **Solidus Temperature** ($T_{solidus}$ in Equation 18.3), and **Liquidus Temperature** ($T_{liquidus}$ in Equation 18.3) for the material being used in your model.

   Setup → **Materials**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 25.2: The Create/Edit Materials Dialog Box for Melting and Solidification



If you are solving for species transport, you need to specify properties for the mixture, including the method by which the **Solidus Temperature** and the **Liquidus Temperature** are calculated. The default method is the **mixing-law** (Equation 18.8 and Equation 18.9 in the Theory Guide), in which the solidus temperature and the liquidus temperature are calculated from the parameters provided for each solute (such as the slope of the liquidus line or partition coefficient). However, a **user-defined** function of type `DEFINE_PROPERTY` can be used to specify both of these temperatures. See the Fluent Customization Manual for examples of `DEFINE_PROPERTY`.

Important

It is highly recommended that you use the same method for specifying the **Solidus Temperature** and the **Liquidus Temperature**.

When defining the mixture, you will also specify the **Mass Diffusivity** ($D_{i,m,\text{liq}}$ in Equation 18.15 and Equation 18.18) and the **Eutectic Temperature** (T_{Eut} in Equation 18.10), as well as the **Pure Solvent Melting Heat** (L in Equation 18.4) and the **Pure Solvent Melting Temperature** (T_{melt} in Equation 18.8 and Equation 18.9). Note that the solvent is the last species listed under **Selected Species** in the **Species** dialog box.

For each solute, you have to specify the **Slope of Liquidus Line** (m_i in Equation 18.8 and Equation 18.9 in the Theory Guide) with respect to the concentration of the solute, the **Partition Coefficient** (K_i in Equation 18.8), the **Eutectic Mass Fraction** ($Y_{i,\text{Eut}}$ in Equation 18.10), and, if **Lever Rule** is selected

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

in the **Solidification and Melting** dialog box, the coefficient for **Diffusion in Solid** ($D_{i,m,\text{sol}}$ in Equation 18.15). It is not necessary to specify m_i, K_i, $Y_{i,\text{Eut}}$, and $D_{i,m,\text{sol}}$ for the solvent.

8. Set the boundary conditions.

   Setup → **Boundary Conditions**

   In addition to the usual boundary conditions, consider the following:

   - If you want to account for the presence of an air gap between a wall and an adjacent solidified region (as described in Contact Resistance at Walls in the Theory Guide), specify a nonzero value, a profile, or a user-defined function for **Contact Resistance** (R_c in Equation 18.23) under **Thermal Conditions** in the Wall Dialog Box (p. 2456).

   - If you want to specify the gradient of the surface tension with respect to the temperature at a wall boundary, you can use the **Marangoni Stress** option for the wall **Shear Condition**. See Marangoni Stress (p. 363) for details.

   - If you want ANSYS Fluent to compute the pull velocities during the calculation, note how your specified velocity conditions are used in this calculation (see Pull Velocity for Continuous Casting in the Theory Guide).

Procedures for Modeling Continuous Casting (p. 1530) contains additional information about modeling continuous casting. See Solution Procedure (p. 1532) and Postprocessing (p. 1532) for information about solving a solidification/melting model and postprocessing the results.

25.2. Procedures for Modeling Continuous Casting

As described in Momentum Equations and Pull Velocity for Continuous Casting in the Theory Guide, you can include the pull velocities in your solidification/melting calculation to model continuous casting. There are three approaches to modeling continuous casting in ANSYS Fluent:

- Specify constant or variable pull velocities.

  To use this approach (the default), do not enable the **Compute Pull Velocities** option.

  If you use this approach, you will need to patch constant values or custom field functions for the pull velocities, after you initialize the solution.

  Solution → **Initialization** → **Patch...**

  See Patching Values in Selected Cells (p. 1593) for details about patching values. Note that it is acceptable to patch values for the pull velocities in the entire domain, because the patched values will be used only if the liquid fraction, β, is less than 1.

- Have ANSYS Fluent compute the pull velocities (using Equation 18.22) during the calculation, based on the specified velocity boundary conditions.

  To use this approach, enable the **Compute Pull Velocities** option. This method is computationally expensive, and is recommended only if the pull velocities are strongly dependent on the location of the liquid-solid interface.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you have ANSYS Fluent compute the pull velocities, then there are no additional inputs or setup procedures beyond those presented in Setup Procedure (p. 1527).

- Have ANSYS Fluent compute the pull velocities just once, and then use those values for the remainder of the calculation.

  To use this approach, perform one iteration with ANSYS Fluent computing the pull velocities, and then turn off the **Compute Pull Velocities** option and continue the calculation. For the remainder of the calculation, ANSYS Fluent will use the values computed for the pull velocities at the first iteration.

25.3. Modeling Thermal and Solutal Buoyancy

When the effects of thermal and solutal buoyancy are present, a flow can be induced inside the domain due to the effect of gravity on the variable density of the medium. In the case of multi-component solidification problems, the density variation takes place due to temperature changes and also due to species concentration gradients near the liquid-solid interface. The flow due to buoyancy with solidification and melting can be modeled in ANSYS Fluent using the thermal and solutal buoyancy options.

For more information on the theory behind buoyancy induced flow in solidification and melting problems, see Thermal and Solutal Buoyancy in the Theory Guide.

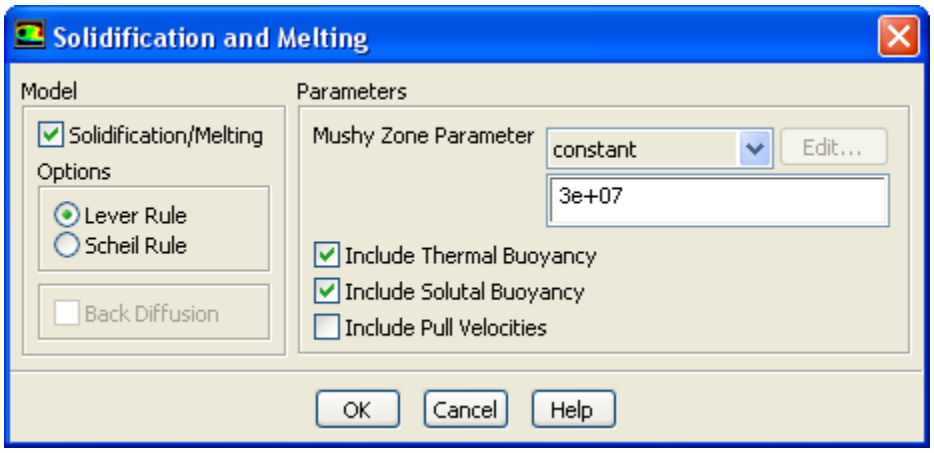
The procedure for setting up a solidification/melting problem is described in Setup Procedure (p. 1527). To include thermal and solutal buoyancy effects, perform the following steps:

1. Enable the **Include Thermal Buoyancy** and **Include Solutal Buoyancy** options in the **Solidification and Melting** dialog box (Figure 25.3: The Solidification and Melting Dialog Box (p. 1531)).

   Note

   The **Include Thermal Buoyancy** and **Include Solutal Buoyancy** options are available only when solidification is modeled with species transport.

   Figure 25.3: The Solidification and Melting Dialog Box



2. Define the operating conditions and properties for modeling thermal buoyancy as described in Natural Convection and Buoyancy-Driven Flows (p. 833).

3. To model solutal buoyancy, specify a value for the **Solutal Expansion Coefficient** for all the species except the last one in the mixture in the **Create/Edit Materials** dialog box.

Note

By default, the eutectic mass fraction of the solute is used as the reference species mass fraction of the solute for the calculation of the body force due to solutal buoyancy. Therefore, no additional input is required. However, in certain applications, it is not always desirable to use the default values of the reference mass fraction. For such cases, the solute mass fraction values can be entered through text user interface as follows:

```
 define/models/solidification-melting? yes
Include Thermal Buoyancy? yes
Include Solutal Buoyancy? yes
Use reference mass fraction of solutes? yes
Reference mass fraction of the species-i "value"
```

25.4. Solution Procedure

Before solving the coupled fluid flow and heat transfer problem, you may want to patch an initial temperature or solve the steady conduction problem as an initial condition. The coupled problem can then be solved as either steady or transient. Because of the nonlinear nature of these problems, however, in most cases a transient solution approach is preferred.

You can specify the under-relaxation factor applied to the liquid fraction equation in the Solution Controls Task Page (p. 2508).

Solution → **Controls**

Specify the desired value in the **Liquid Fraction Update** field under **Under-Relaxation Factors**. This sets the value of α_β in the following equation for updating the liquid fraction from one iteration (n) to the next ($n+1$):

$$\beta_{n+1}=\beta_n+\alpha_\beta\Delta\beta \tag{25.1}$$

where $\Delta\beta$ is the predicted change in liquid fraction.

In many cases, there is no need to change the default value of α_β. If, however, there are convergence difficulties, reducing the value may improve the solution convergence. Convergence difficulties can be expected in steady-state calculations, continuous casting simulations, simulations involving multicomponent solidification, and simulations where a large value of the mushy zone constant is used.

25.5. Postprocessing

For solidification/melting calculations, you can generate graphical plots or alphanumeric reports of the following items depending on which other models are enabled in the simulation. These quantities are available in the **Solidification/Melting...** category of the variable selection drop-down list that appears in postprocessing dialog boxes:

- **Liquid Fraction**
- **Contact Resistivity**

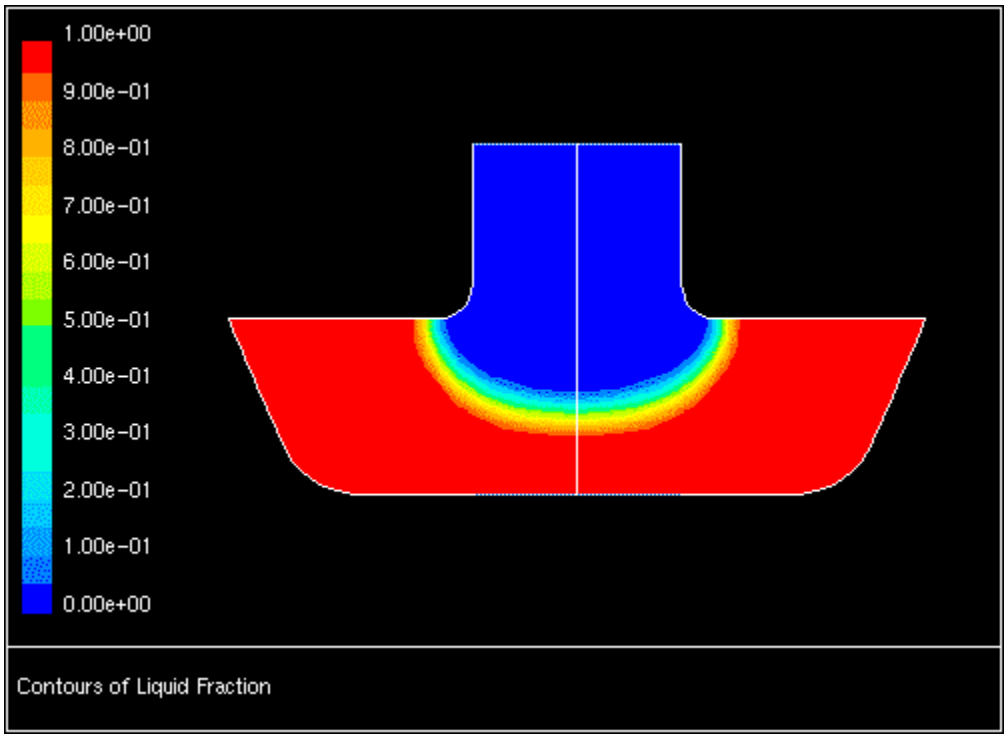
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Pull Velocity** (**X**, **Y**, **Z**, **Axial**, **Radial**, and **Swirl** components)
- **Liquidus Temperature**
- **Solidus Temperature**

The **Liquid Fraction** and **Contact Resistivity** solution variables are available for all solidification/melting simulations. The **Pull Velocity** components are available only if you are including pull velocities (either computed or specified) in the simulation. **Liquidus Temperature** and **Solidus Temperature** are available only if the **Species** model is set up to perform a multi-component solidification/melting simulation. See Field Function Definitions (p. 1931) for a complete list of field functions and their definitions. Displaying Graphics (p. 1747) and Reporting Alphanumeric Data (p. 1885) explain how to generate graphics displays and reports of data.

Figure 25.4: Liquid Fraction Contours for Continuous Crystal Growth (p. 1533) shows filled contours of liquid fraction for a continuous crystal growth simulation.

Figure 25.4: Liquid Fraction Contours for Continuous Crystal Growth



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information
of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 26: Modeling Eulerian Wall Films

The Eulerian Wall Film (EWF) model can be used to predict the creation and flow of thin liquid films on the surface of walls. This chapter presents information about the basic functionality of the Eulerian Wall Film (EWF) model. Additional information about the model is provided in the following sections:

26.1. Limitations
26.2. Setting Eulerian Wall Film Model Options
26.3. Setting Eulerian Wall Film Solution Controls
26.4. Setting Eulerian Wall Film Boundary, Initial, and Source Term Conditions
26.5. Postprocessing the Eulerian Wall Film

For more information about Eulerian Wall Film model theory, see Eulerian Wall Films in the Theory Guide. For more information about setting boundary conditions for liquid films at wall boundaries, see Wall Film Conditions for Walls (p. 381).

26.1. Limitations

The following limitations exist for the Eulerain Wall Film model:

- The Eulerian Wall Film model is available for 3D geometries only.
- Many models (for example, VOF multiphase flow or radiation) will not interact correctly with the film model without first modifying the boundary conditions using UDFs.
- Wallfilm behavior at junctions with baffles (zero-thickness walls) may lead to unphysical results due to the local mesh topology (wall, wall-shadow) and should be used with care, that is, isolated film walls must not share a common edge.
- The wall film can only be single-component, but not multi-component.
- The Eulerian Wall Film model is not compatible with non-conformal interfaces.
- The Eulerian Wall Film model is not compatible with mesh operations in Fluent (such as mesh adaption, cell separation, face zone extrusion, cell zone type change, and so on).

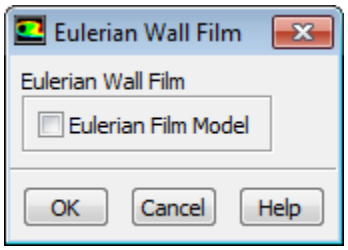
26.2. Setting Eulerian Wall Film Model Options

You can enable the Eulerian Wall Film model by selecting **Eulerian Wall Film** from the **Models** task page.

Setup → **Models** → **Eulerian Wall Film** **Edit...**

*This opens the **Eulerian Wall Film** dialog box.*

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



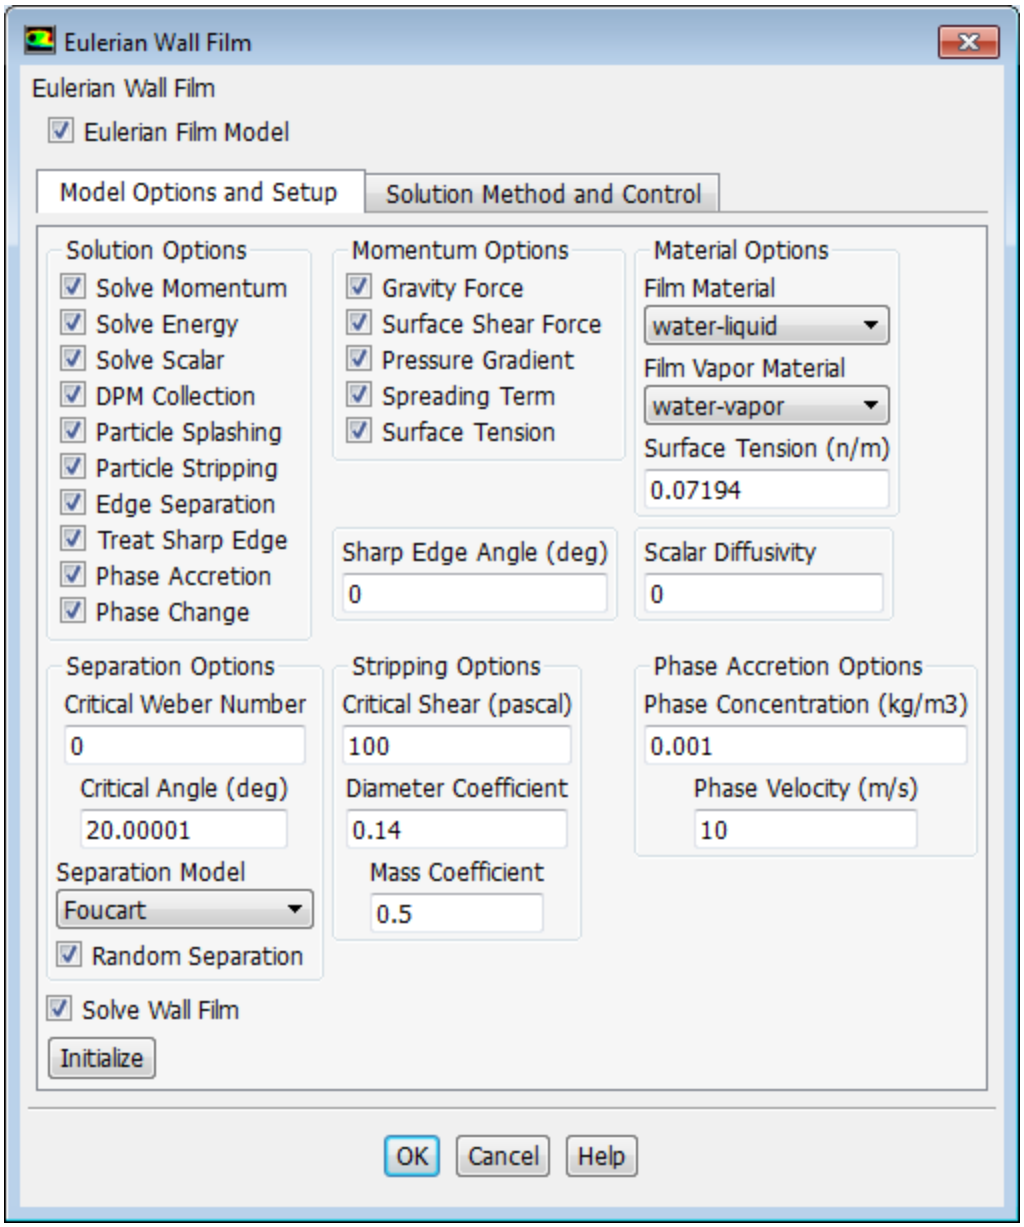
Once you open the Eulerian Wall Film Dialog Box (p. 2294), you can select the **Eulerian Wall Film** check box to enable the model so that you can use it in your simulation. Enabling the model expands the dialog box to reveal additional model options and solution controls.

Important

If you want to modify your mesh in Fluent, you must first disable the Eulerian Wall Film model. Once you save the modified mesh, you must re-enable the Eulerian Wall Film model and re-initialize your case.

You can set general Eulerian Wall Film model options in the **Model Options and Setup** tab of the **Eulerian Wall Film** dialog box. This tab contains controls for specific solution, discrete phase model (DPM), and material options for the Eulerian Wall Film model.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the **Model Options and Setup** tab, the following options and controls are available:

Solve Momentum

specifies whether the momentum equation (see Equation 19.2 in the *Fluent Theory Guide*) is solved for the wall film or not. In the **Momentum Options** group box, you can individually select each term of the equation for inclusion in the calculations.

Note that **Spreading Term** and **Surface Tension** under **Momentum Options** are available only when **Pressure Gradient** is selected.

Solve Energy

specifies whether the energy equation (see Equation 19.3 in the *Fluent Theory Guide*) is solved for the wall film or not.

Solve Scalar

specifies whether the passive scalar transport equation Equation 19.36 is solved for the wall film or not. When the **Solve Scalar** option is enabled, you can specify **Scalar Diffusivity**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

DPM Collection
includes discrete phase particles and their interaction with the film model (see DPM Collection in the *Fluent Theory Guide*). You can select:

- **Particle Splashing**

  You can specify splashing options in the **Wall Film** tab of the **Wall** dialog box. For details, see Setting Eulerian Wall Film Boundary, Initial, and Source Term Conditions (p. 1542).

- **Particle Stripping** and specify the settings under the **Stripping Options** group box (for details, see Film Separation in the *Fluent Theory Guide*)

- **Edge Separation** and specify the settings under the **Separation Options** group box (for details, see Film Separation in the *Fluent Theory Guide*)

  Note that **Random Separation** means that the locations at which the newly spawned particles are injected (due to film separation) are randomly selected along the edge at which the separation takes place.

Treat Sharp Edge
accounts for the effects of sharp edges and specify **Sharp Edge Angle**. When the **Treat Sharp Edge** option is enabled and where the edge angle is smaller than the **Sharp Edge Angle**, the film wall edge is treated as a boundary edge (namely, the film becomes detached from the wall, rather than bending around the edge and attaching to the wall). If the Discrete Phase Model has been enabled along with the Eulerian Wall Film model, then the film wall edge is treated as a separation edge.

Phase Accretion
accounts for the effect of the interaction of the wall film with Eulerian and Mixture multiphase flow (see Secondary Phase Accretion in the *Fluent Theory Guide*). This option enables you to compute the secondary phase collection efficiency on a wall surface. This option is only available when the Eulerian or Mixture (with Slip Velocity) Multiphase model is enabled.

Note

The following considerations should be taken into account when the Eulerian Wall Film model is used with the Eulerian or Mixture multiphase models:

- You must create temporary placeholder injections in order to model edge separation and edge stripping.
- The material properties for the secondary phase should be the same as the DPM particles.
- The name of the secondary phase material should be included in the name of the DPM particle's material and should be appended with the string '-particle' (for example, if the secondary phase material name is *waterliquid- eulerian*, then the DPM particle's material name should be *waterliquid-eulerian-particle*).

Phase Change
accounts for phase changes between the film material (liquid) and the gas species (vapor) (see Coupling of Wall Film with Mixture Species Transport in the *Fluent Theory Guide*). This option enables you to set the following:

- **Film Vapor Material**—in the **Material Options** group box.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Phase change parameters—in the **Wall Film** tab of the **Wall** dialog box. For details, see Setting Eulerian Wall Film Boundary, Initial, and Source Term Conditions (p. 1542).

Note

The liquid film can only be a single-component fluid. The secondary phase that is intended for the film material cannot be a mixture of species.

Material Options
allow to select film material and film vapour material (available only for Phase Change calculations) and specify wall film surface tension.

Note

The type of material for a wall film must be **Fluid**, **Droplet Particle**, or **Inert Particle** (fluid).

You can define density, viscosity, specific heat, and thermal conductivity of a wall film material using one of the following methods:
- constant
- polynomial (including piecewise linear and piecewise polynomial)
- compressible liquid (for fluid density)
- user-defined (not available for fluid specific heat)

Solve Wall Film
enables you to skip the wall film solution during the gas phase solution, but keep the variables and setup active.

Note

The wall film cannot be solved without first initializing the wall film model (using the **Initialize** button) to initialize the wall film variables and prepare the solver for the solution procedure.

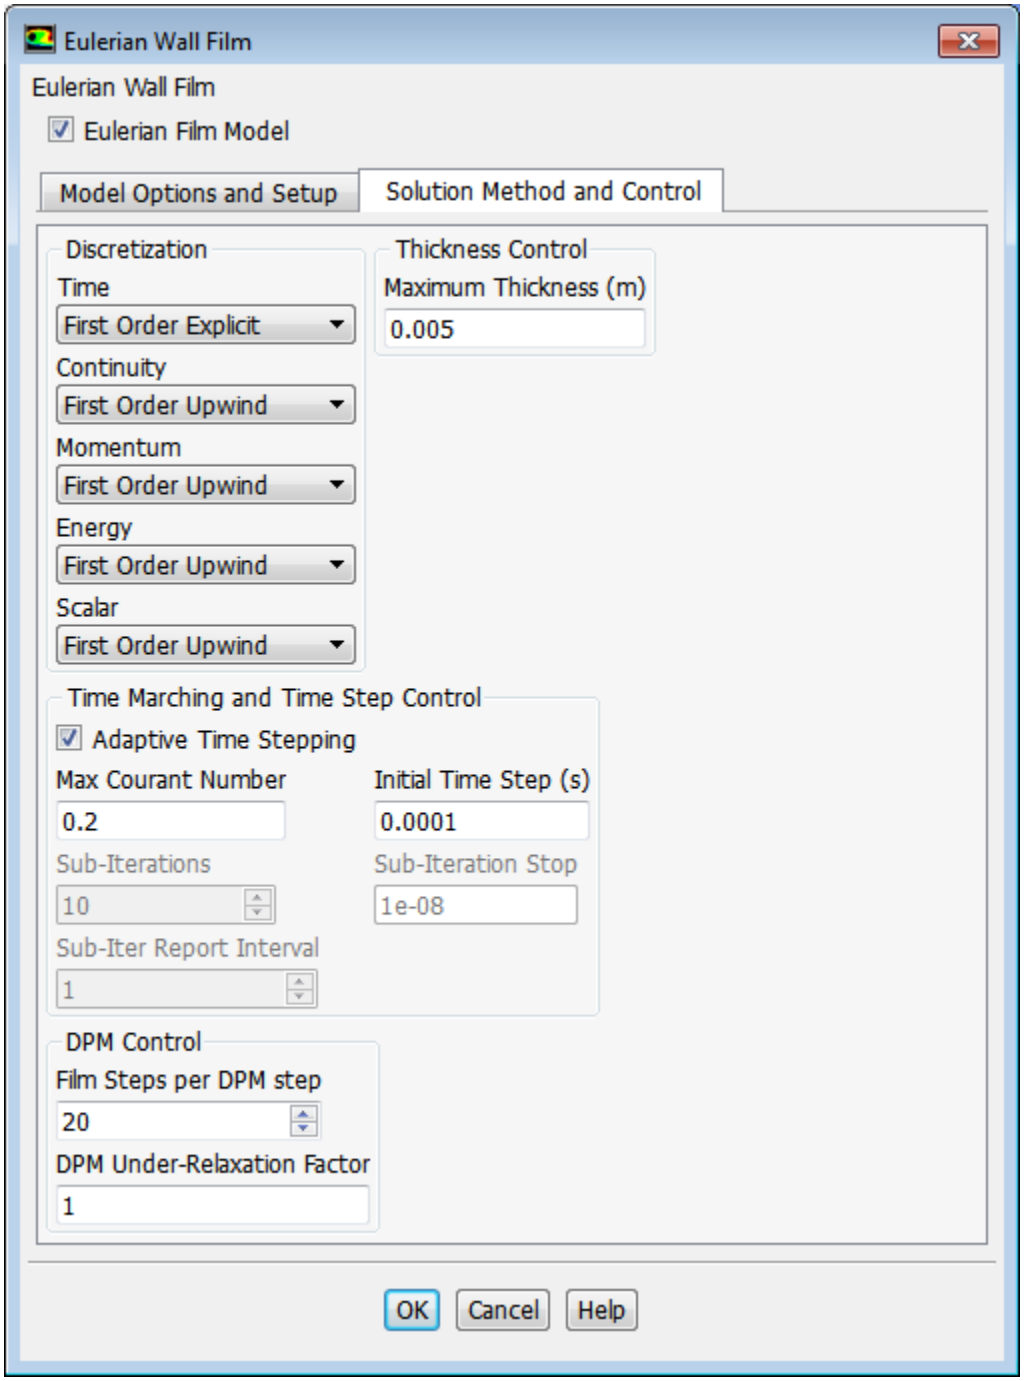
You can also use the `define/models/eulerian-wallfilm/model-options` text command to define the settings and the discretization methods for the Eulerian Wall Film model.

26.3. Setting Eulerian Wall Film Solution Controls

You can set solution controls for the Eulerian Wall Film model in the **Solution Method and Control** tab of the **Eulerian Wall Film** dialog box. This tab contains controls for specific temporal and spatial discretization options for the Eulerian Wall Film model.

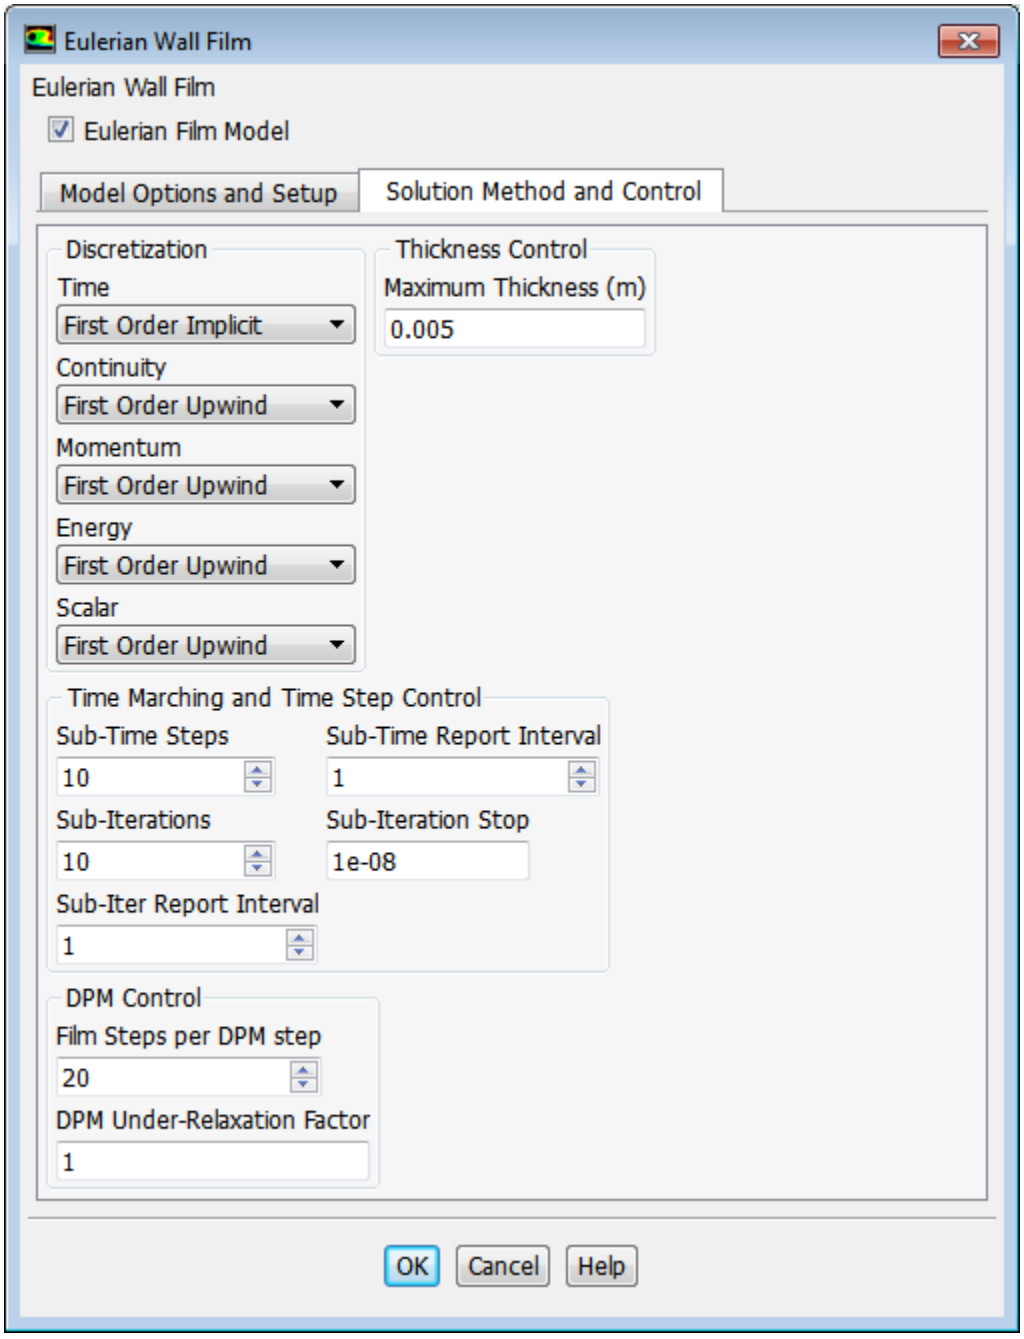
Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 26.1: Eulerian Wall Film Solution Controls (Steady Flow)



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 26.2: Eulerian Wall Film Solution Controls (Unsteady Flow)



In the **Solution Method and Control** tab, you can set the following:

- Temporal and spatial (continuity, momentum, energy, and passive scalar) discretization methods under **Discretization**.
- **Maximum Thickness** for the film.

  The **Maximum Thickness** setting will limit the film thickness by removing material from the film where this value is exceeded.
- For steady state calculations (Figure 26.1: Eulerian Wall Film Solution Controls (Steady Flow) (p. 1540)):

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You can specify the film model specific **Time Step** (the Eulerian Wall Film model is always transient), or you can select the **Adaptive Time Stepping** option to set the **Max. Courant Number** and the **Initial Time Step** (see Steady Flow).

- For transient cases (Figure 26.2: Eulerian Wall Film Solution Controls (Unsteady Flow) (p. 1541)):

  You can define the **Number of Time Steps** per main flow time step and the **Sub-Time Report Interval** for film calculation reporting. Note that the first and the last sub-time steps are always reported.

- For either first or second order implicit time discretization calculations:

  You can control the number of film **Sub-Iterations**, the value of **Sub-Iteration Stop** below which the film sub-iteration stops, and the **Sub-Iter Report Interval** for film sub-iteration reporting. Note that the first and the last sub-iterations are always reported.

- If **DPM Collections** is selected in the **Model Options and Setup** tab:

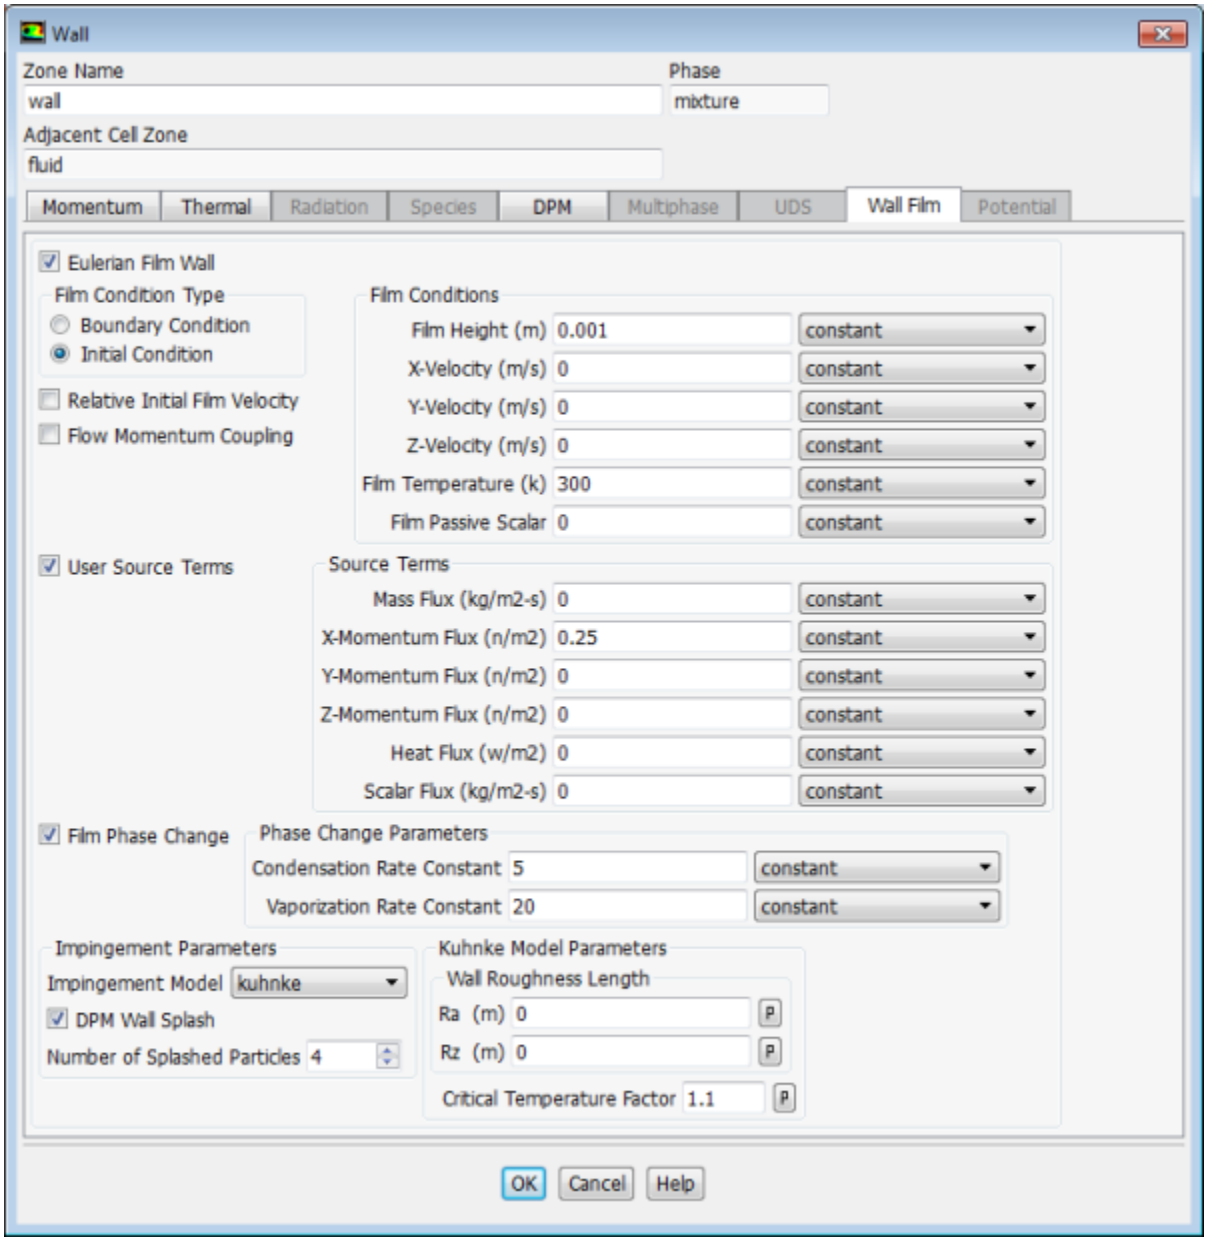
  You can set how often the DPM phase is calculated for the film by specifying a value for the **Film Steps per DPM Step** These controls are only available if **Interaction with Continuous Phase** is disabled in the **Discrete Phase Model** dialog box.

26.4. Setting Eulerian Wall Film Boundary, Initial, and Source Term Conditions

In the **Wall** dialog box, under the **Wall Film** tab, you can set boundary, initial, and source term conditions for liquid films on specified wall boundaries. When you select the **Eulerian Film Wall** option, Fluent solver designates the wall as a film wall. Wall film equations are only solved on designated film walls.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 26.3: Wall Dialog Box (Initial Conditions)



The following types of film conditions exist in ANSYS Fluent:

- **Boundary Condition**: Is where film mass, momentum, energy and scalar quantities are introduced to the wall film solution domain.

  You can enter values for the following quantities:

  – **Film Mass Flux**

  – **X-Momentum Flux**, **Y-Momentum Flux**, and **Z-Momentum Flux**

  – **Incoming Film Temperature**

  – **Film Passive Scalar Flux**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For moving wall simulations, you can specify the film momentum flux relative to the wall on which liquid film is defined by selecting **Relative Film Momentum Flux**. Note that this option is only available when **Moving Wall** is selected in the **Wall** dialog box and/or **Frame Motion** is selected in the **Fluid** dialog box.

the film momentum flux or initial velocity inputs will be relative to the wall on which liquid film is defined.

- **Initial Condition**: Is the initial state of wall film.

  You can set values for the following quantities:

  – **Film Height**

  – **X-Velocity**, **Y-Velocity**, and **Z-Velocity** components

  – **Film Temperature**

  – **Film Passive Scalar**

  For moving wall simulations, you can specify the initial velocity relative to the wall on which liquid film is defined by selecting **Relative Initial Film Velocity**. Note that this option is only available when **Moving Wall** is selected in the **Wall** dialog box and/or **Frame Motion** is selected in the **Fluid** dialog box.

  If you select the **User Source Terms** option (available only with initial conditions), you can also specify additional source terms to the film continuity, momentum, energy, and passive scalar equations by setting values for the following quantities:

  – **Mass Flux**

  – **X-Momentum Flux**, **Y-Momentum Flux**, and **Z-Momentum Flux**

  – **Heat Flux**

  – **Scalar Flux**

For both boundary and initial conditions, if you select the **Flow Momentum Coupling** option, the liquid film and the gas flow shares the same velocity at the interface of the liquid-gas interface using a two-way coupling. If you clear this option, the coupling between the liquid film and the gas flow occurs only one-way, namely, while the gas flow impacts the film flow, the film flow does not impact the bulk of the gas flow.

When the **Phase Change** option is selected in the **Eulerian Wall Film** dialog box, you can enable the **Film Phase Change** for the selected film wall and specify **Condensation Rate Constant** and **Vaporization Rate Constant** (C_{con} and C_{vap} in Equation 19.28 in the *Fluent Theory Guide*). You can also specify condensation and vaporization rates using user-defined profile UDFs. Note that such UDFs must return the relevant rates in kg/s. For more information on profile user-defined functions, see the separate Fluent Customization Manual.

When the **DPM Collection** option is selected in the **Eulerian Wall Film** dialog box, you can select a particle-wall impingement model and specify relevant model parameters in the **Wall** dialog box. The following impingement models are available in ANSYS Fluent:

- `stanton-rutland` (see The Stanton-Rutland Model in the *Fluent Theory Guide* for details)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- kuhnke (see The Kuhnke Model in the *Fluent Theory Guide* for details)

  For the Kuhnke model, you must specify the following model parameters:

  – **Ra**: The wall mean roughness that is used to compute K_{cold} in Equation 16.258 in the *Fluent Theory Guide*

  – **Rz**: The average surface roughness that is used to compute splashed particle reflection angle distribution Equation 16.270 in the *Fluent Theory Guide*.

  – **Critical Temperature Factor**: The dimensionless variable that is used to determine the impingement regime transition temperature in Equation 16.250 in the *Fluent Theory Guide*.

Note

You can also add an impingement effect via UDFs as described in Hooking `DEFINE_IMPINGEMENT` UDFs, Hooking `DEFINE_FILM_REGIME` UDFs, and Hooking `DEFINE_SPLASHING_DISTRIBUTION` UDFs in the *Fluent Customization Manual*. Note that UDFs settings will override those for the impingement/splashing model selected for the Eulerian wall film boundary condition.

In addition, when **Particle Splashing** is selected in the **Eulerian Wall Film** dialog box, you can select **DPM Wall Splash** and specify **Number of Splashed Particles**.

26.5. Postprocessing the Eulerian Wall Film

When using the Eulerian Wall Film model, the following additional variables will be available for postprocessing (see Field Function Definitions (p. 1931) for their definitions):

- **Film Thickness**
- **Film Mass**
- **Film Temperature** (when **Solve Energy** is enabled)
- **Film X-Velocity**
- **Film Y-Velocity**
- **Film Z-Velocity**
- **Film Velocity Magnitude**
- **Film Surface X-Velocity**
- **Film Surface Y-Velocity**
- **Film Surface Z-Velocity**
- **Film Surface Velocity Magnitude**
- **Film Surface Temperature** (when **Solve Energy** is enabled)
- **Film Passive Scalar** (when **Solve Scalar** is enabled)
- **Film Density** (when film material density is non-constant)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Film Effective Pressure**
- **Film Courant Number**
- **Film Weber Number**
- **Film Stripped Mass** (when **Particle Stripping** is enabled)
- **Film Stripped Diam** (when **Particle Stripping** is enabled)
- **Film DPM Mass Source** (when **DPM Collection** is enabled)
- **Film DPM Energy Source** (when **DPM Collection** and **Solve Energy** are enabled)
- **Film DPM X-Momentum Source** (when **DPM Collection** is enabled)
- **Film DPM Y-Momentum Source** (when **DPM Collection** is enabled)
- **Film DPM Z-Momentum Source** (when **DPM Collection** is enabled)
- **Film Separated Mass** (when **Edge Separation** is enabled)
- **Film Secondary Phase Mass** (when **Phase Accretion** is enabled)
- **Film Secondary Phase Collection Coef** (when **Phase Accretion** is enabled)

You can report on the mass and energy fluxes for the Eulerian Wall Film model using the **Flux Reports** dialog box (see Generating a Flux Report (p. 1911)), for domain boundaries such as inlets, outlets, and so on, as well as wall boundaries.

Results → Reports → Fluxes **Edit...**

The **Film Mass Flow Rate** and **Film Heat Transfer Rate** are available as options in the **Flux Reports** dialog box when the **Eulerian Wall Film** model is enabled.

Note

The energy flux report only accounts for the heat transfer rate through the external boundary. It does not consider heat transfer at gas-liquid interfaces or heat transfer due to phase change or film-DPM interaction.

You can also report on the mass flow rate and heat transfer rate using the User Interface (TUI) as follows:

- For mass flow rate, enter the text command `report/fluxes/film-mass-flow`.
- For heat transfer rate, enter the text command `report/fluxes/film-heat-transfer`.

You will be prompted for the boundary face zone IDs for which the report will be generated, and whether or not you want to save the reported values to a file. ANSYS Fluent will either print the report in the console or write it to the file you have specified.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Chapter 27: Modeling Electric Potential Field

This chapter provides details about how to model and simulate the electric potential field in ANSYS Fluent. The theoretical aspects of the electric potential model are presented in Electric Potential in the *Fluent Theory Guide*. Additional information about the model is provided in the following sections:

27.1. Overview and Limitations
27.2. Using the Electric Potential Model
27.3. Postprocessing the Electric Potential Field

27.1. Overview and Limitations

The ANSYS Fluent electric potential model allows for predicting the electric potential field and its effects. The electric potential model can be used separately (for example, to compute electric static force for charged particles in a DPM calculation) or in combination with other ANSYS Fluent models.

The electric potential solver has been integrated with the electrochemical reaction model (Electrochemical Reactions in the *Fluent Theory Guide*). When you enable the electrochemistry in your case, ANSYS Fluent automatically enables the electric potential solver. However, if you want to use the electric potential model along with other ANSYS Fluent models, you need to manually enable it as described in Using the Electric Potential Model (p. 1547).

Using the electric potential solver, you can simulate the electric potential field in both fluid and solid zones.

When defining the boundary conditions for the electric potential field, you can specify either potential or current density at the external walls.

The following limitations exist for the electric potential model:

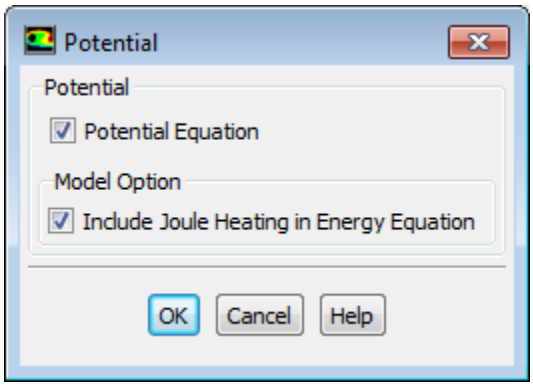
- The electric potential model cannot be used with multiphase flows.
- The electric potential model cannot be used in simulations with walls that have a shell conduction boundary condition.

27.2. Using the Electric Potential Model

The procedure for setting up the electric potential model is described below. Note that only steps that are pertinent to electric potential field modeling are listed here. You will also need to define the other settings (such as other material properties, boundary conditions, other models) as usual. For information about inputs related to other ANSYS Fluent models that you are using in conjunction with the electric potential model, refer to the appropriate sections for those models.

1. In the **Potential** dialog box, which is opened from the **Model**/**Electric Potential** tree item, enable the **Potential Equation** option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



Once the **Potential Equation** is enabled, the electric conductivity material property for fluid, solid, and mixture materials defined in your case will appear in the **Create/Edit Materials** dialog box.

2. If you want to include Joule heating in the energy equation (Equation 5.1 in the *Fluent Theory Guide*), under the **Model Option** group box, enable **Include Joule Heating in Energy Equation**.

Note

The **Include Joule Heating in Energy Equation** option appears in the **Potential** dialog box only when **Energy Equation** is enabled in the **Energy** dialog box.

---

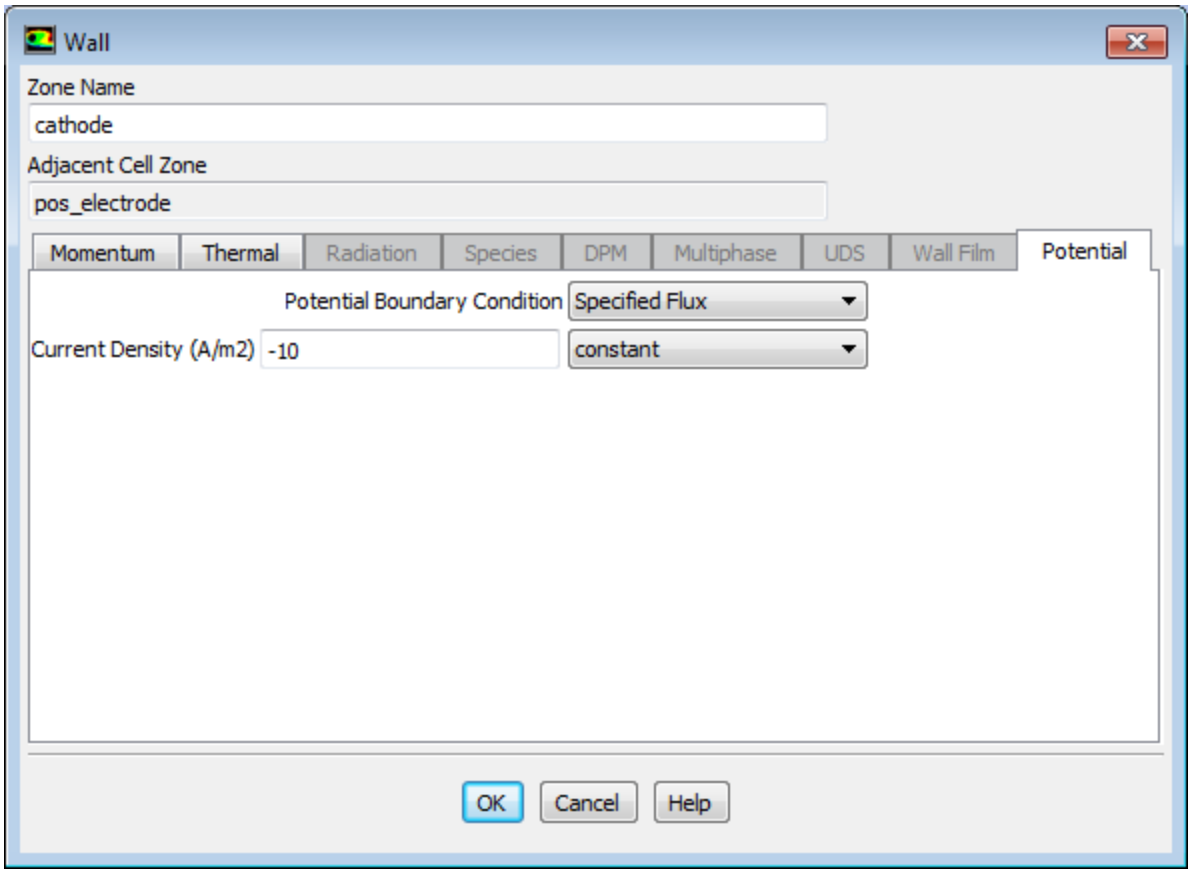
3. In the **Create/Edit Materials** dialog box, under **Properties**, specify electric conductivity for the conductive materials defined in your simulation.

Setup → **Materials**

4. Define boundary conditions on conductive external (one-sided) walls.

Setup → **Boundary Conditions**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.



In the **Potential Boundary Condition** drop-down list, if you select:

- **Specified Flux**, you can specify the **Current Density** at the boundary wall.
- **Specified Value**, you can specify the **Potential** at the boundary wall.

5. If required, specify electric potential conditions on other boundaries in the **Potential** tab of the boundary conditions dialog boxes. Note that the default setting, zero current flux, is suitable for most problems and needs not be changed.

27.3. Postprocessing the Electric Potential Field

For potential field calculations, you can generate graphical plots or alphanumeric reports of the following items (see Field Function Definitions (p. 1931) for their definitions). These quantities are available in the variable selection drop-down lists that appear in postprocessing dialog boxes:

- **Electric Potential** (in the **Potential...** category)
- **Electric Conductivity** (in the **Properties...** category)
- **Current Magnitude** (in the **Potential...** category)
- **Joule Heat Source** (in the **Potential...** category)

You can also generate vector plots of the electric current fields by selecting **Electric Current** in the **Vectors of** drop-down list inVectors Dialog Box (p. 2831).

28.21. Convergence and Stability
28.22. Solution Steering

28.1. Overview of Using the Solver

In ANSYS Fluent, two solver technologies are available:

- pressure-based
- density-based

Both solvers can be used for a broad range of flows, but in some cases one formulation may perform better (that is, yield a solution more quickly or resolve certain flow features better) than the other. The pressure-based and density-based approaches differ in the way that the continuity, momentum, and (where appropriate) energy and species equations are solved, as described in Overview of Flow Solvers in the Theory Guide.

The pressure-based solver traditionally has been used for incompressible and mildly compressible flows. The density-based approach, on the other hand, was originally designed for high-speed compressible flows. Both approaches are now applicable to a broad range of flows (from incompressible to highly compressible), but the origins of the density-based formulation may give it an accuracy (that is shock resolution) advantage over the pressure-based solver for high-speed compressible flows.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Two formulations exist under the density-based solver: implicit and explicit. The density-based explicit and implicit formulations solve the equations for additional scalars (for example, turbulence or radiation quantities) sequentially. The implicit and explicit density-based formulations differ in the way that they linearize the coupled equations. For more details about the solver formulations, see Overview of Flow Solvers in the Theory Guide.

Due to broader stability characteristics of the implicit formulation, a converged steady-state solution can be obtained much faster using the implicit formulation rather than the explicit formulation. However, the implicit formulation requires more memory than the explicit formulation.

Two algorithms also exist under the pressure-based solver in ANSYS Fluent: a segregated algorithm and a coupled algorithm. In the segregated algorithm the governing equations are solved sequentially, segregated from one another, while in the coupled algorithm the momentum equations and the pressure-based continuity equation are solved in a coupled manner. In general, the coupled algorithm significantly improves the convergence speed over the segregated algorithm, however, the memory requirement for the coupled algorithm is more than the segregated algorithm.

When selecting a solver and an algorithm you must consider the following issues:

- The model availability for a given solver.
- Solver performance for the given flow conditions.
- The size of the mesh under consideration and the available memory on your machine. This issue could be an important factor in deciding whether to use an explicit or implicit formulation when the density-based solver is selected, or to use a segregated or coupled algorithm when the pressure-based solver is selected.

The following two lists highlight the model availability for each solver:

Important

Note that the pressure-based solver provides several physical models or features that are not available with the density-based solver:

- Cavitation model
- Volume-of-fluid (VOF) model
- Multiphase mixture model
- Eulerian multiphase model
- Non-premixed combustion model
- Premixed combustion model
- Partially premixed combustion model
- Composition PDF transport model
- Soot model
- Rosseland radiation model
- Melting/solidification model

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Shell conduction model
- Floating operating pressure
- Fixed variable option
- Physical velocity formulation for porous media
- Specified mass flow rate for streamwise periodic flow

The following features are available with the density-based solver, but not with the pressure-based solver:

- Wet steam multiphase model

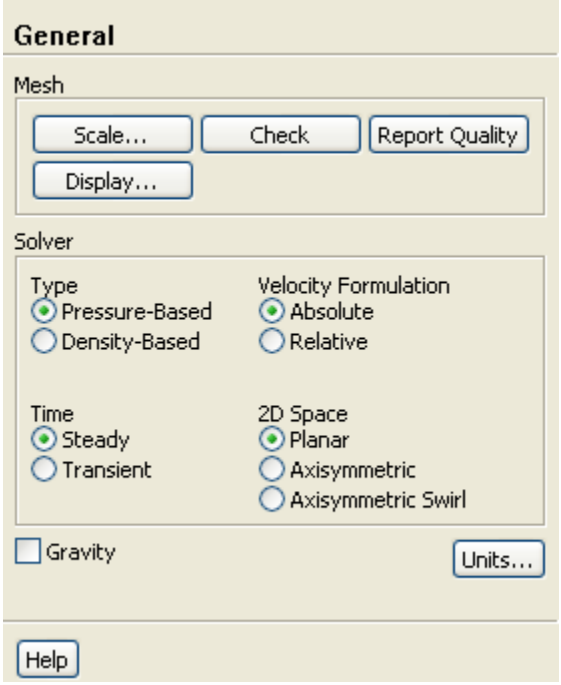
For additional information, see the following sections:
28.1.1. Choosing the Solver

28.1.1. Choosing the Solver

To choose one of the solvers, you will use the General Task Page (p. 2160) (Figure 28.1: The General Task Page (p. 1553)).

Setup → General

Figure 28.1: The General Task Page



To use the pressure-based solver, retain the default selection of **Pressure-Based** under **Solver**.

To use the density-based solver, select **Density-Based** under **Solver**.

After you have defined your model and specified which solver you want to use, you are ready to run the solver. The following steps outline a general procedure you can follow:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

1. (pressure-based solver only) Select the pressure-velocity coupling method (see Choosing the Pressure-Velocity Coupling Method (p. 1561)).

2. Choose the spatial discretization scheme and, for the pressure-based solver, the pressure interpolation scheme (see Choosing the Spatial Discretization Scheme (p. 1554)).

3. (pressure-based solver only) Select the porous media velocity method (see Porous Media Conditions (p. 261)).

4. Select how you want the derivatives to be evaluated by choosing a gradient option (see Evaluation of Gradients and Derivatives in the Theory Guide).

5. Set the under-relaxation factors (see Setting Under-Relaxation Factors (p. 1564)).

6. (density-based explicit formulation only) Set up the FAS multigrid (see Turning On FAS Multigrid (p. 1575)).

7. Make any additional modifications to the solver settings that are suggested in the chapters or sections that describe the models you are using.

8. Enable the appropriate solution monitors (see Monitoring Solution Convergence (p. 1624)).

9. Initialize the solution (see Initializing the Solution (p. 1591)).

10. Start calculating (see Performing Steady-State Calculations (p. 1600) for steady-state calculations, or Performing Time-Dependent Calculations (p. 1608) for time-dependent calculations).

11. If you have convergence trouble, try one of the methods discussed in Convergence and Stability (p. 1667).

The default settings for the first three items listed above are suitable for most problems and need not be changed. The following sections outline how these and other solution parameters can be changed, and when you may want to change them.

28.2. Choosing the Spatial Discretization Scheme

Gradients are needed not only for constructing values of a scalar at the cell faces, but also for computing secondary diffusion terms and velocity derivatives. For more information about the different gradients, see Evaluation of Gradients and Derivatives in the Theory Guide.

The three gradients that are available in ANSYS Fluent are

- **Green-Gauss Cell Based**
- **Green-Gauss Node Based**
- **Least Squares Cell Based**

The gradient options are selectable from the **Gradient** drop-down list, in the **Solution Methods** task page.

Solution → **Methods**

In addition, ANSYS Fluent allows you to choose the discretization scheme for the convection terms of each governing equation. (Second-order accuracy is automatically used for the viscous terms.) By default, single-phase problems using either the pressure-based or density-based solver are solved using second-order upwind discretization for the convection terms of the flow equations and all scalar equations except those for turbulence quantities, which are solved using first-order upwind discretization. For

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

multiphase flows, the flow equations use first-order upwind discretization by default. For a complete description of the discretization schemes available in ANSYS Fluent, see Discretization in the Theory Guide.

In addition, when you use the pressure-based solver, you can specify the pressure interpolation scheme. For a description of the pressure interpolation schemes available in ANSYS Fluent, see Pressure Interpolation Schemes in the Theory Guide.

For additional information, see the following sections:

28.2.1. First-Order Accuracy vs. Second-Order Accuracy
28.2.2. Other Discretization Schemes
28.2.3. Choosing the Pressure Interpolation Scheme
28.2.4. Choosing the Density Interpolation Scheme
28.2.5. High Order Term Relaxation (HOTR)
28.2.6. User Inputs

28.2.1. First-Order Accuracy vs. Second-Order Accuracy

When the flow is aligned with the mesh (for example, laminar flow in a rectangular duct modeled with a quadrilateral or hexahedral mesh) the first-order upwind discretization may be acceptable. When the flow is not aligned with the mesh (that is, when it crosses the mesh lines obliquely), however, first-order convective discretization increases the numerical discretization error (numerical diffusion). For triangular and tetrahedral meshes, since the flow is never aligned with the mesh, you will generally obtain more accurate results by using the second-order discretization. For quad/hex meshes, you will also obtain better results using the second-order discretization, especially for complex flows.

In summary, while the first-order discretization generally yields better convergence than the second-order scheme, it generally will yield less accurate results, especially on tri/tet meshes. See Convergence and Stability (p. 1667) for information about controlling convergence.

For most cases, you will be able to use the second-order scheme from the start of the calculation. In some cases, however, you may need to start with the first-order scheme and then switch to the second-order scheme after a few iterations. For example, if you are running a high-Mach-number flow calculation that has an initial solution much different than the expected final solution, you will usually need to perform a few iterations with the first-order scheme and then turn on the second-order scheme and continue the calculation to convergence. Alternatively, full multigrid initialization is also available for some flow cases that allow you to proceed with the second-order scheme from the start.

For a simple flow that is aligned with the mesh (for example, laminar flow in a rectangular duct modeled with a quadrilateral or hexahedral mesh), the numerical diffusion will be naturally low, so you can generally use the first-order scheme instead of the second-order scheme without any significant loss of accuracy.

Finally, if you run into convergence difficulties with the second-order scheme, you should try the first-order scheme instead.

28.2.1.1. First-to-Higher Order Blending

While the higher-order scheme may result in greater accuracy, it can also result in convergence difficulties and instabilities at certain flow conditions. On the other hand, using a first-order scheme may not provide the desired accuracy. One approach to achieving improved accuracy while maintaining good stability is to use a discretization blending factor. This feature is available for both density-based and pressure-based solvers and can be invoked using the following text command:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`solve → set → numerics`

Enter a value between `0` and `1` when asked for the blending factor: `1st-order to higher-order blending factor [min=0.0 - max=1.0]`

A blending factor of `0` reduces the gradient reconstruction to a first-order discretization scheme, whereas `1` will recover high-order discretization. A blending factor of less than `1` (typically 0.75 or 0.5) will make the convective fluxes more diffusive, which in some flow conditions can stabilize a solution that is otherwise unstable when the full higher-order discretization scheme is employed.

Important

Note that in order to use this feature effectively, make sure that one of the allowed higher order discretization schemes is selected for the desired variables in the **Solution Methods** task page.

28.2.2. Other Discretization Schemes

The QUICK and third-order MUSCL discretization schemes may provide better accuracy than the second-order scheme for rotating or swirling flows. The QUICK scheme is applicable to quadrilateral or hexahedral meshes, while the MUSCL scheme is used on all types of meshes. In general, however, the second-order scheme is sufficient and the QUICK scheme will not provide significant improvements in accuracy.

Important

If QUICK is used for hybrid meshes, it will be used only for quadrilateral and hexahedral cells. Second-order upwind discretization will be applied to all other cells.

A power law scheme is also available, but it will generally yield the same accuracy as the first-order scheme.

The bounded central differencing and central differencing schemes are available only when you are using the LES, DES, SAS, SBES, and SDES turbulence models, and the central differencing scheme should be used only when the mesh spacing is fine enough so that the magnitude of the local Peclet number (see Equation 21.6 in the Theory Guide) is less than 1.

A modified HRIC scheme (see Modified HRIC Scheme in the Theory Guide) is also available for VOF simulations using either the implicit or explicit formulation.

28.2.3. Choosing the Pressure Interpolation Scheme

As discussed in Pressure Interpolation Schemes in the Theory Guide, a number of pressure interpolation schemes are available when the pressure-based solver is used in ANSYS Fluent. For most cases the second-order scheme is acceptable, but some types of models may benefit from one of the other schemes:

- For mixture or VOF multiphase models, either the PRESTO! or body-force-weighted schemes should be used and only these schemes are made available. The default in these cases is PRESTO!.
- For problems involving large body forces, the body-force-weighted scheme is recommended.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For flows with high swirl numbers, high-Rayleigh-number natural convection, high-speed rotating flows, and flows in strongly curved domains, use the PRESTO! scheme.

Note that you will not specify the pressure interpolation scheme if you are using the Eulerian multiphase model. ANSYS Fluent will use the solution method described in Solution Method in ANSYS Fluent in the Theory Guide for Eulerian multiphase calculations.

28.2.4. Choosing the Density Interpolation Scheme

As discussed in Density Interpolation Schemes in the Theory Guide, four density interpolation schemes are available when the pressure-based solver is used to solve a single-phase compressible flow.

The second-order upwind scheme (the default) provides reasonable stability for the discretization of the pressure-correction equation, and gives good results for most classes of flows. The first-order upwind scheme will provide greater stability, but may tend to smooth shocks in compressible flows. If you are calculating a compressible flow with shocks you should use the second-order-upwind or QUICK scheme. Using the QUICK scheme for all variables, including density, is highly recommended for compressible flows with shocks when using quadrilateral, hexahedral, or hybrid meshes. The third-order MUSCL scheme is applicable to arbitrary meshes and has the potential to improve spatial accuracy for all types of meshes by reducing numerical diffusion.

Important

In the case of multiphase flows, the selected density scheme is applied to the compressible phase and arithmetic averaging is used for incompressible phases.

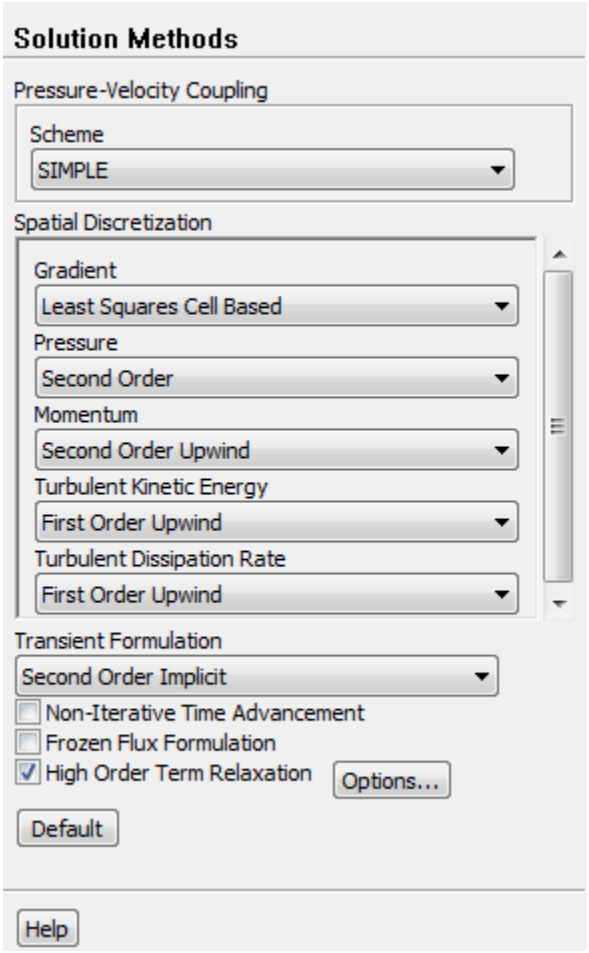
28.2.5. High Order Term Relaxation (HOTR)

The purpose of the relaxation of high order terms is to improve the startup and the general solution behavior of flow simulations when higher order spatial discretizations are used (higher than first). It has also shown to prevent convergence stalling in some cases. Such high-order terms can be of significant importance in certain cases and lead to numerical instabilities. This is particularly true at aggressive solution settings. In such cases, high order relaxation is a useful strategy to minimize your interaction during the solution. This can be an effective alternative to starting the solution first order, then switching to second order spatial discretization at a later stage.

The **High Order Term Relaxation** option can be enabled from the **Solution Methods** task page, as shown in Figure 28.2: The Solution Methods Task Page for the HOTR Option (p. 1558).

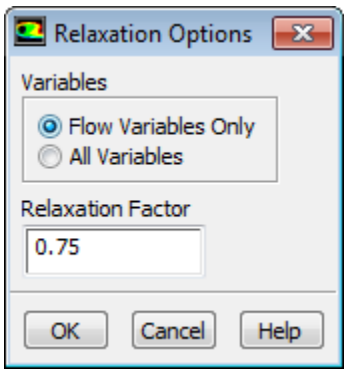
Solution → **Methods**

Figure 28.2: The Solution Methods Task Page for the HOTR Option



Further control of **High Order Term Relaxation** can be obtained after clicking **Options...** and making the necessary selections and settings in the **Relaxation Options** dialog box (Figure 28.3: The Relaxation Options Dialog Box (p. 1558)).

Figure 28.3: The Relaxation Options Dialog Box



You have the option of selecting **All Variables** to be under-relaxed instead of only the default flow variables (**Flow Variables Only**).

- If you select **Flow Variables Only**, then the following variables will be under-relaxed:
  - Velocity components

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

  - Pressure
  - Energy
  - Density
  - Turbulence quantities (excluding Reynolds stresses)
  - Volume fraction

- If you select **All Variables**, then relaxation is applied to each variable discretized with a higher order scheme.

The default values for the **Relaxation Factor** is 0.25 for steady-state cases and 0.75 for transient cases. The same factor is applied to all equations solved.

For theoretical information about high order term relaxation, see High Order Term Relaxation in the Theory Guide.

28.2.5.1. Limitations

The following limitations exist when using the **High Order Term Relaxation** option:

- The **High Order Term Relaxation** option is not available when the **Non-Iterative Time Advancement** option is enabled, since the simulation would not achieve the required level of high order spatial accuracy.
- In general, high order term relaxation is available for transient flows. Nevertheless, it should be used with care. To achieve high order accuracy at convergence for each time step, you must increase the number of iterations per time step to ensure that the original convergence criteria have been met.
- When the QUICK scheme is selected for specific transport equations, no under-relaxation is applied to this equation.

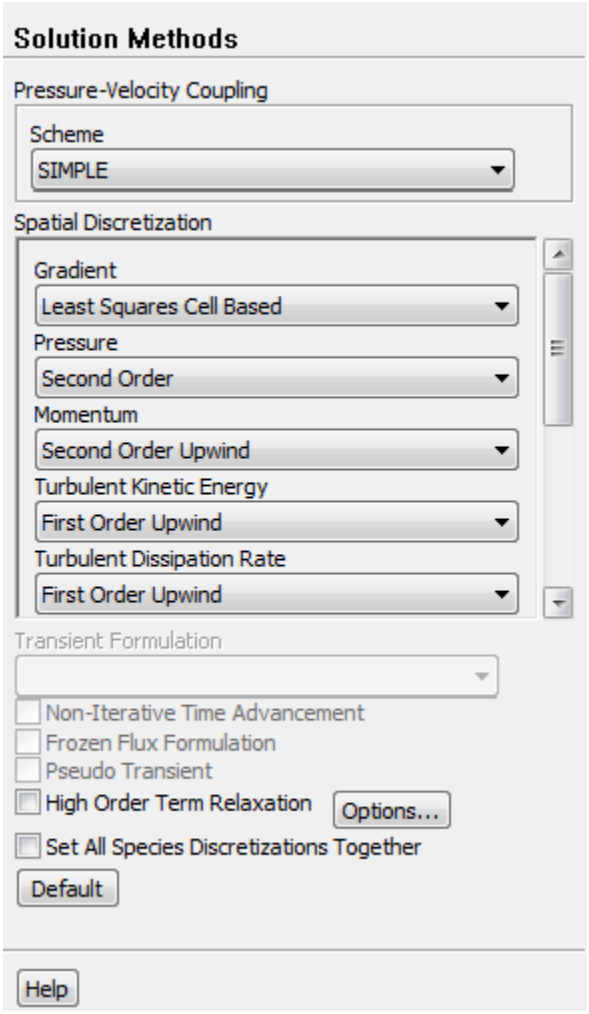
28.2.6. User Inputs

You can specify the discretization scheme and, for the pressure-based solver, the pressure interpolation scheme in the Solution Methods Task Page (p. 2504) (Figure 28.4: The Solution Methods Task Page for the Pressure-Based Segregated Algorithm (p. 1560)).

Solution → **Methods**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.4: The Solution Methods Task Page for the Pressure-Based Segregated Algorithm



For each scalar equation listed under **Spatial Discretization** (**Momentum**, **Energy**, **Turbulent Kinetic Energy**, and so on, for the pressure-based solver or **Turbulent Kinetic Energy**, **Turbulent Dissipation Rate**, and so on, for the density-based solver) you can choose **First Order Upwind**, **Second Order Upwind**, **Power Law**, **QUICK**, **Third-Order MUSCL**, or (if you are using the LES turbulence model) **Bounded Central Differencing** (the default) or **Central Differencing** in the adjacent drop-down list. For the density-based solver, you can choose either **First Order Upwind**, **Second Order Upwind**, or **Third-Order MUSCL** for the **Flow** equations (which include momentum and energy). Note that the task page shown in Figure 28.4: The Solution Methods Task Page for the Pressure-Based Segregated Algorithm (p. 1560) is for the pressure-based solver.

If you are using the pressure-based solver, select the pressure interpolation scheme under **Spatial Discretization**, in the drop-down list next to **Pressure**. You can choose **Standard**, **PRESTO!**, **Linear**, **Second Order**, or **Body Force Weighted**.

Important

The low-order formulation of PRESTO! can be applied by limiting the high-order terms for the PRESTO! scheme. This is done using the following text command:

`solve → set → numerics`

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When asked `limit high-order terms for PRESTO! pressure scheme?`, enter `yes`.

This modification can be used to stabilize the solution process when the pressure-based coupled algorithm is used and when the original PRESTO! scheme either fails to converge or produces unphysical oscillations (wiggles) in the pressure field.

If you are using the pressure-based solver and your flow is compressible (that is, you are using the ideal gas law for density), select the density interpolation scheme under **Spatial Discretization**, in the drop-down list next to **Density**. You can choose **First Order Upwind**, **Second Order Upwind**, **QUICK** or **Third-Order MUSCL**. (Note that **Density** will not appear for incompressible flows.)

If you enable the VOF model while using the pressure-based solver, the volume fraction interpolation schemes that are available are **Geo-Reconstruct**, **CICSAM**, **Modified HRIC**, and **QUICK**.

If your case involves species transport, you can set the scheme for the individual species as **First Order Upwind**, **Second Order Upwind**, **Power Law**, **QUICK**, or **Third-Order MUSCL**. However, if you want all your species to use the same discretization scheme, then rather than setting each one individually, simply enable the **Set All Species Discretizations Together** option. Notice that you will no longer see your list of individual species, instead a **Species** field will appear with the scheme of your choice.

If you change the settings for the **Spatial Discretization**, but you then want to return to ANSYS Fluent's default settings, you can click the **Default** button.

Important

If your mesh topology has step-wise prism mesh near the walls, do not use node-based gradients with MUSCL.

28.3. Pressure-Based Solver Settings

For additional information, see the following sections:

28.3.1. Choosing the Pressure-Velocity Coupling Method
28.3.2. Setting Under-Relaxation Factors
28.3.3. Setting Solution Controls for the Non-Iterative Solver

28.3.1. Choosing the Pressure-Velocity Coupling Method

ANSYS Fluent provides four segregated types of algorithms: SIMPLE, SIMPLEC, PISO, and (for time-dependent flows using the **Non-Iterative Time Advancement** option (NITA)) Fractional Step (FSM). These schemes are referred to as the pressure-based segregated algorithm. Steady-state calculations will generally use SIMPLE or SIMPLEC, while PISO is recommended for transient calculations. PISO may also be useful for steady-state and transient calculations on highly skewed meshes. In ANSYS Fluent, using the **Coupled** algorithm enables full pressure-velocity coupling, hence it is referred to as the pressure-based coupled algorithm.

Important

Pressure-velocity coupling is relevant only for the pressure-based solver.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.3.1.1. SIMPLE vs. SIMPLEC

In ANSYS Fluent, both the standard SIMPLE algorithm and the SIMPLEC (SIMPLE-Consistent) algorithm are available. SIMPLE is the default, but many problems will benefit from using SIMPLEC, particularly because of the increased under-relaxation that can be applied, as described below.

For relatively uncomplicated problems (laminar flows with no additional models enabled) in which convergence is limited by the pressure-velocity coupling, you can often obtain a converged solution more quickly using SIMPLEC. With SIMPLEC, the pressure-correction under-relaxation factor is generally set to 1.0, which aids in convergence speed-up. In some problems, however, increasing the pressure-correction under-relaxation to 1.0 can lead to instability due to high mesh skewness. For such cases, you will need to use one or more skewness correction schemes, use a slightly more conservative under-relaxation value (up to 0.7), or use the SIMPLE algorithm. For complicated flows involving turbulence and/or additional physical models, SIMPLEC will improve convergence only if it is being limited by the pressure-velocity coupling. Often it will be one of the additional modeling parameters that limits convergence; in this case, SIMPLE and SIMPLEC will give similar convergence rates.

28.3.1.2. PISO

The PISO algorithm (see PISO in the Theory Guide) with neighbor correction is highly recommended for all transient flow calculations, especially when you want to use a large time step. (For problems that use the LES turbulence model, which usually requires small time steps, using PISO may result in an increased computational expense, so SIMPLE or SIMPLEC should be considered instead.) PISO can maintain a stable calculation with a larger time step and an under-relaxation factor of 1.0 for both momentum and pressure. For steady-state problems, PISO with neighbor correction does not provide any noticeable advantage over SIMPLE or SIMPLEC with optimal under-relaxation factors.

PISO with skewness correction is recommended for both steady-state and transient calculations on meshes with a high degree of distortion.

When you use PISO neighbor correction, under-relaxation factors of 1.0 or near 1.0 are recommended for all equations. If you use just the PISO skewness correction for highly-distorted meshes (without neighbor correction), set the under-relaxation factors for momentum and pressure so that they sum to 1 (for example, 0.3 for pressure and 0.7 for momentum). If you use both PISO methods, follow the under-relaxation recommendations for PISO neighbor correction, above.

For most problems, it is not necessary to disable the default coupling between neighbor and skewness corrections. For highly distorted meshes, however, disabling the default coupling between neighbor and skewness corrections is recommended.

28.3.1.3. Fractional Step Method

The Fractional Step method (FSM), described in Fractional-Step Method (FSM) in the Theory Guide, is available when you choose to use the NITA scheme (that is, the **Non-Iterative Time Advancement** option in the **Solution Methods** task page). With the NITA scheme, the FSM is slightly less computationally expensive compared to the PISO algorithm. Whether you select FSM or PISO depends on the application. For some problems (for example, simulations that use VOF), FSM could be less stable than PISO.

In most cases, the default values for the solution methods are enough to set a robust convergence of the internal pressure correction sub-iterations due to skewness. Only very complex problems (for example, moving deforming meshes, sliding interfaces, the VOF model) could require a reduction of relaxation for pressure up to a value of 0.7 or 0.8.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.3.1.4. Coupled

Selecting **Coupled** from the **Pressure-Velocity Coupling** drop-down list indicates that you are using the pressure-based coupled algorithm, described in Coupled Algorithm in the Theory Guide. This solver offers some advantages over the pressure-based segregated algorithm. The pressure-based coupled algorithm obtains a more robust and efficient single phase implementation for steady-state flows. It is not available for cases using the **Non-Iterative Time Advancement** option (NITA).

Note

In some cases using porous jump boundary conditions, the **Coupled** scheme may suffer from convergence issues that do not respond to changes in the coupled solver settings. This behavior depends on the specific flow configuration and porous jump boundary condition values. If convergence instability is observed in cases using porous jump boundary conditions and the **Coupled** scheme, it is recommended that you change the pressure-velocity coupling to one of the segregated schemes.

28.3.1.5. User Inputs

You can specify the pressure-velocity coupling method in the Solution Methods Task Page (p. 2504) (Figure 28.4: The Solution Methods Task Page for the Pressure-Based Segregated Algorithm (p. 1560)).

Solution → **Methods**

Choose **SIMPLE**, **SIMPLEC**, **PISO**, **Fractional Step**, or **Coupled** in the **Pressure-Velocity Coupling** drop-down list.

If you choose **PISO**, the task page will expand to show the additional parameters for pressure-velocity coupling. By default, the number of iterations for **Skewness Correction** and **Neighbor Correction** are set to `1`. If you want to use only **Skewness Correction**, then set the number of iterations for **Neighbor Correction** to `0`. Likewise, if you want to use only **Neighbor Correction**, then set the number of iterations for **Skewness Correction** to `0`. For most problems, you do not need to change the default iteration values. By default, the **Skewness-Neighbor Coupling** option is enabled to allow for a more economical, but a less robust variation of the PISO algorithm.

If you choose **SIMPLEC** under **Pressure-Velocity Coupling**, you must also set the **Skewness Correction**, whose default value is `0`.

If you choose **Coupled**, you will have to specify the **Courant** number in the **Solution Controls** task page, which is set at `200` by default. You will also specify the **Explicit Relaxation Factors** for **Momentum** and **Pressure**, which are set at `0.75` by default. For more information about these options, refer to Pressure-Velocity Coupling and Steady-State Iterative Algorithm in the Theory Guide.

If high-order momentum discretization is used, you may need to decrease the explicit relaxation to `0.5`. For cases with very skewed meshes, the run can be stabilized by further reduction of the explicit relaxation factor to `0.25`. If ANSYS Fluent immediately diverges in the AMG solver, then the CFL number is too high and should be reduced. Reducing the CFL number below `10` is not recommended since it would be better to use the segregated algorithm for the pressure-velocity coupling.

In most transient cases, the CFL number should be set to 10^7 with an explicit relaxation of 1.0.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you choose **Coupled** and enable the **Pseudo Transient** option, you will set the **Pseudo Transient Explicit Relaxation Factors** in the **Solution Controls** task page, as described in Setting Pseudo Transient Explicit Relaxation Factors (p. 1602).

28.3.2. Setting Under-Relaxation Factors

The pressure-based solver uses under-relaxation of equations to control the update of computed variables at each iteration (as described in Under-Relaxation of Equations in the Theory Guide). This means that all equations solved using the pressure-based solver, *including the non-coupled equations solved by the density-based solver* (turbulence and other scalars, as discussed in Density-Based Solver in the Theory Guide), will have under-relaxation factors associated with them.

In ANSYS Fluent, the default under-relaxation parameters for all variables are set to values that are near optimal for the largest possible number of cases. These values are suitable for many problems, but for some particularly nonlinear problems (for example, some turbulent flows or high-Rayleigh-number natural-convection problems) it is prudent to reduce the under-relaxation factors initially.

It is good practice to begin a calculation using the default under-relaxation factors. If the residuals continue to increase after the first 4 or 5 iterations, you should reduce the under-relaxation factors.

Occasionally, you may make changes in the under-relaxation factors and resume your calculation, only to find that the residuals begin to increase. This often results from increasing the under-relaxation factors too much. A cautious approach is to save a data file before making any changes to the under-relaxation factors, and to give the solution algorithm a few iterations to adjust to the new parameters. Typically, an increase in the under-relaxation factors brings about a slight increase in the residuals, but these increases usually disappear as the solution progresses. If the residuals jump by a few orders of magnitude, you should consider halting the calculation and returning to the last good data file saved.

Note that viscosity and density are under-relaxed from iteration to iteration. Also, if the enthalpy equation is solved directly instead of the temperature equation (that is, for non-premixed combustion calculations), the update of temperature based on enthalpy will be under-relaxed. To see the default under-relaxation factors, you can click the **Default** button in the Solution Controls Task Page (p. 2508).

For most flows, the default under-relaxation factors do not usually require modification. If unstable or divergent behavior is observed, however, you need to reduce the under-relaxation factors for pressure, momentum, k, and ε from their default values to about 0.2, 0.5, 0.5, and 0.5. (It is usually not necessary to reduce the pressure under-relaxation for SIMPLEC.) In problems where density is strongly coupled with temperature, as in very-high-Rayleigh-number natural- or mixed-convection flows, it is wise to also under-relax the temperature equation and/or density (that is, use an under-relaxation factor less than 1.0). Conversely, when temperature is not coupled with the momentum equations (or when it is weakly coupled), as in flows with constant density, the under-relaxation factor for temperature can be set to 1.0.

For other scalar equations (for example, swirl, species, mixture fraction and variance) the default under-relaxation may be too aggressive for some problems, especially at the start of the calculation. You may want to reduce the factors to 0.8 to facilitate convergence.

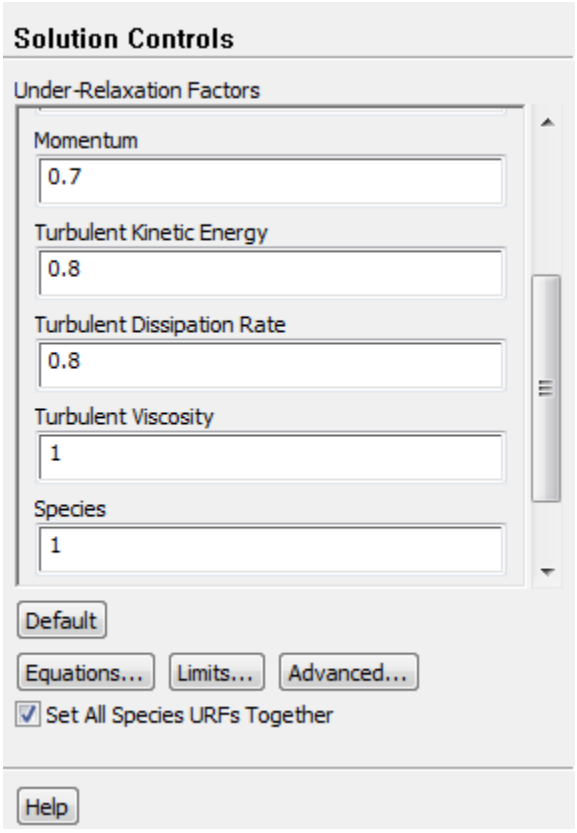
28.3.2.1. User Inputs

You can modify the under-relaxation factors in the Solution Controls Task Page (p. 2508) (Figure 28.5: The Solution Controls Task Page for the Pressure-Based Solver (p. 1565)).

Solution → **Controls**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.5: The Solution Controls Task Page for the Pressure-Based Solver



You can set the under-relaxation factor for each equation in the field next to its name under **Under-Relaxation Factors**.

Important

If you are using the pressure-based solver, all equations will have an associated under-relaxation factor (see Under-Relaxation of Equations in the Theory Guide). If you are using the density-based solver, only those equations that are solved sequentially (see Density-Based Solver in the Theory Guide) will have under-relaxation factors.

If your case involves species transport, you can set the under-relaxation factors for each of the listed species. If you want all your species to use the same under-relaxation factors, simply enable the **Set All Species URFs Together** option. Notice that you will no longer see your list of individual species, instead a **Species** field will appear where you will specify the under-relaxation factor.

If you change under-relaxation factors, but you then want to return to ANSYS Fluent's default settings, you can click the **Default** button.

Note that with optimal settings, the convergence of the coupled pressure-velocity algorithm will be limited by the segregated solution of other scalar equations, for example, turbulence. For optimum solver performance, you will need to increase the relaxation factors for these equations to a value greater than the default values.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.3.3. Setting Solution Controls for the Non-Iterative Solver

You can use the non-iterative solver (see Time-Advancement Algorithm in the Theory Guide) for transient problems in order to increase the speed and efficiency of the calculations. You can also obtain a steady solution using the non-iterative multiphase solver for multiphase flows with quasi-steady conditions.

The settings for the non-iterative solver should provide control over the maximum number of sub-iterations for each individual equation. The criteria for convergence include the **Correction Tolerance** (defined by the overall accuracy), **Residual Tolerance** (controlling the solution of the linear equations), and the individual **Relaxation Factor**. The default control settings are optimally designed in order to get a second-order accurate solution. These controls are accessible via the **Expert** tab, in the **Advanced Solution Controls** dialog box (Figure 28.6: The Advanced Solution Controls Dialog Box for the Pressure-Based Segregated Non-Iterative Solver (p. 1567)).

To use ANSYS Fluent's non-iterative transient solver in order to boost the efficiency of transient simulations:

1. Go to the **Solution Methods** task page.

   Solution → **Methods**

2. Enable **Non-Iterative Time-Advancement**.

3. Under **Pressure-Velocity Coupling**, select a scheme from the drop-down list:

   - For single phase flows: You can select either the **Fractional Step** or **PISO** scheme. For the **PISO** scheme, you can set the value for the **Neighbor Correction**. Skewness correction is performed automatically.

   - For Eulerian multiphase flows: Select the **Phase Coupled SIMPLE**. This is the only pressure scheme available for NITA multiphase simulations.

Once you enable **Non-Iterative Time-Advancement**, you can set the parameters that control the sub-iterations for individual equations under **Non-Iterative Solver Controls** in the **Advanced Solution Controls** dialog box (Figure 28.6: The Advanced Solution Controls Dialog Box for the Pressure-Based Segregated Non-Iterative Solver (p. 1567)). See User Inputs (p. 1566) for details.

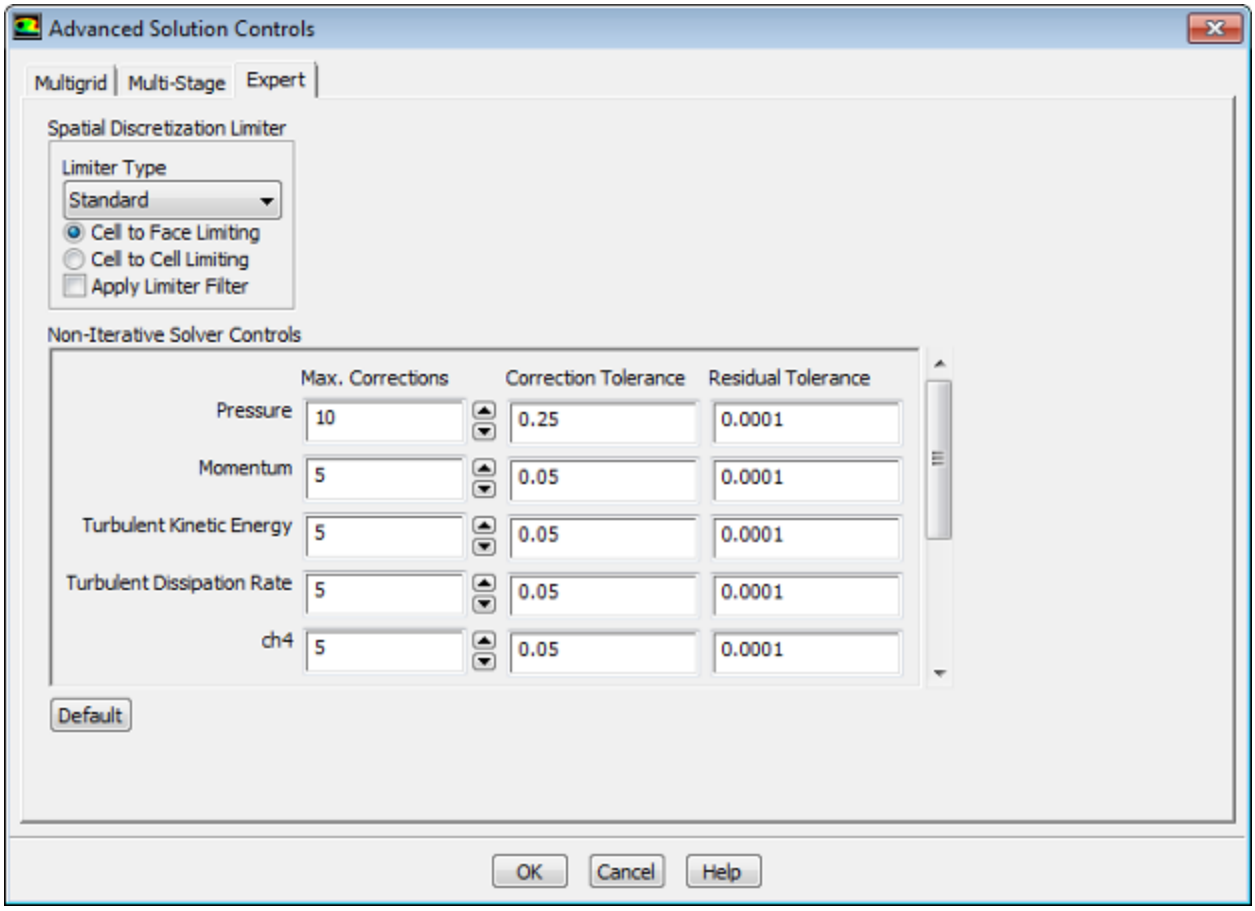
28.3.3.1. User Inputs

You can modify the non-iterative solution controls in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.6: The Advanced Solution Controls Dialog Box for the Pressure-Based Segregated Non-Iterative Solver (p. 1567)).

Solution → **Controls** → **Advanced...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.6: The Advanced Solution Controls Dialog Box for the Pressure-Based Segregated Non-Iterative Solver



Under **Non-Iterative Solver Controls**, there are several parameters that control the sub-iterations for the individual equations.

The sub-iterations for an equation stop when the total number of sub-iterations exceeds the value specified for **Max. Corrections**, regardless of whether or not the convergence criteria (described below) are met.

The sub-iterations for an equation end when the ratio of the residuals at the current sub-iteration and the first sub-iteration is less than the value specified in the **Correction Tolerance** field. You can monitor the details of the sub-iteration convergence by looking at the AMG solver performance (that is, setting the **Verbosity** field in the **Multigrid** tab in the **Advanced Solution Controls** dialog box to **1**). Be sure to pay attention to the residuals for the current sub-iteration (that is, the residual for the 0-th AMG cycle at the current sub-iteration) and the initial residual of the time step (that is, the residual for the 0-th AMG cycle of the first sub-iteration). The ratio of these two residuals is what is controlled by the **Correction Tolerance** field. These two residuals are also the residuals plotted when using the **Residual Monitor** panel and reported in the ANSYS Fluent console at the end of a time step. Note that the residuals reported at the end of a time step can be scaled or unscaled, depending on the settings in the **Residual Monitor** dialog box. The residuals reported when monitoring the AMG solver performance are always unscaled.

For each interim sub-iteration, the AMG cycles continue until the usual AMG termination criteria (0.1 by default, and set in the **Multigrid** tab) are met. However, for the last sub-iteration (that is, either when the maximum number of sub-iterations are reached or when the correction tolerance is satisfied), the AMG cycles continue until the ratio of the residual at the current cycle to the initial residual (the residual

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

for the 0-th AMG cycle of the first sub-iteration of the time step) drops below the value specified for **Residual Tolerance**. You may want to adjust the **Residual Tolerance**, depending on the time step selected. The default **Residual Tolerance** should be well suited for moderate time steps (that is, for cell CFL numbers of 1 to 10). Note that you can display the cell CFL numbers for unsteady problems by selecting **Cell Courant Number** in the **Velocity...** category of all postprocessing dialog boxes. For very small time steps (cell CFL <<1), the diagonal dominance of the system is very high and the convergence should be driven further by reducing the **Residual Tolerance** value. For larger time steps (cell CFL >>1), it may be possible that the residual tolerance cannot be reached due to round-off errors, and unless the **Residual Tolerance** value is increased, AMG cycles can be wasted. Again, this can be monitored by monitoring the AMG solver performance.

The **Relaxation Factor** field defines the explicit relaxation (see Under-Relaxation of Variables in the Theory Guide) of variables between sub-iterations. The relaxation factors can be used to prevent the solution from diverging. They should be left at their default values of 1, unless divergence is detected. If the solution diverges:

- For single phase flows: You should first try to stabilize the solution by lowering the relaxation factors for pressure to 0.7–0.8, and by reducing the time step.
- For Eulerian multiphase flows: Consider lowering the explicit pressure relaxation factor to about 0.1. This may help when meshes are poor, because a poor mesh will significantly affect the pressure gradient, which in turn may generate large source terms in the governing equations resulting in poor convergence. You can set the under-relaxation factors for the other flow variables to higher values (0.8-1.0).

Expert Options

- To obtain diagnostics on convergence of sub-iterations for individual equations, use the following text command:

  ```
  solve/set/nita-expert-controls/set-verbosity

  verbosity [0] 1
  ```

  The output information may help you to judge whether the specified number of sub-iterations is sufficient to reach the correction tolerance and also to diagnose the source of the solution divergence.

- For NITA cases with **PISO** selected as a **Pressure-Velocity Coupling** scheme, you can enable coupling of the neighbor and skewness corrections with the following TUI command:

  ```
  solve/set/nita-expert-controls/skewness-neighbor-coupling

  enable skewness neighbor coupling for nita [no] yes
  ```

  For more information about this option, see Skewness - Neighbor Coupling in the *Fluent Theory Guide*.

Compatibility with Other ANSYS Fluent Models

The following is a list of models that are compatible with the non-iterative solver:

- Inviscid flow (excluding ideal gas)
- Laminar flow
- All models of turbulence (including LES and DES), except RSM

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- S2S radiation model
- Heat transfer
- Non-reacting species transport
- General compressible flows (most subsonic and some transonic applications)
- VOF multiphase model (most applications)
- Phase change (solidification and melting)
- Porous media model (isotropic resistance)
- Multiphase model with Multi-Fluid VOF
- Multiphase RSM turbulence model

The following is a list of models that are compatible with the non-iterative solver, but may result in some instabilities and inaccuracies for certain flow conditions:

- MDM
- Non-Newtonian fluids
- General compressible flows (aerospace supersonic applications)
- Reacting species and any type of combustion including PDF

The following is a list of models that are not compatible with the non-iterative solver:

- Mixture model
- Radiation models (except S2S)
- DPM, spark, and crevice models
- UDS transport
- Porous jump
- Porous media model (anisotropic resistance)
- RSM turbulence model

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- Floating operating pressure

Important

The PRESTO! pressure interpolation scheme, when used with the non-iterative time-advancement solver, is less stable than in the case of the iterative time-advancement solver. As a consequence, smaller time steps may be required.

Important

As mentioned above, the default control settings are optimally designed to obtain a second-order solution. In order to save CPU time, in cases where transient accuracy is not a main concern (that is, first-order integration in time and space), or when NITA is used to converge toward a steady-state solution, you may want to set the **Max. Corrections** value to 1 in the **Advanced Solution Controls** dialog box (**Expert** tab) for all transport equations except pressure.

28.4. Density-Based Solver Settings

To use the density-based solver you must first select the solver type, and determine if the simulation is steady-state or transient from the **General** Task Page (see Choosing the Solver (p. 1553)). The density based solver settings are available mainly in two task pages: the Solution Methods Task Page (p. 2504) and the Solution Controls Task Page (p. 2508).

In the **Solution Methods** task page, you can select the following:

- Solution formulation type: Implicit or Explicit
- Flux Scheme type : Roe-FDS, AUSM or (Low Diffusion Roe-FDS)
- Flow equation and model equation spatial discretization accuracy
- For the steady-state solution method, you can select additional solution options to accelerate convergence
  - Pseudo transient solution method
  - Convergence acceleration for stretched meshes
- For the transient formulation you can select
  - 1st-Order implicit
  - 2nd-order implicit and for the explicit solver formulation, you can also select the explicit transient formulation

In the **Solution Controls** task page, you can select the following:

- For the density-based explicit solver, you will specify the Courant number, FAS multigrid level, and Residual smoothing
- For the density-based implicit solver, you will need to enter only the Courant number

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- For both solver methods, you will enter the under-relaxation factors associated with other equations solved with the flow equations, such as equations of the turbulence model

The above options can be found in the following sections:
28.4.1. Changing the Courant Number
28.4.2. Convective Flux Types
28.4.3. Convergence Acceleration for Stretched Meshes (CASM)
28.4.4. Specifying the Explicit Relaxation
28.4.5. Turning On FAS Multigrid

28.4.1. Changing the Courant Number

For ANSYS Fluent's density-based solver, the main control over the time-stepping scheme is the Courant number (CFL). The time step is proportional to the CFL, as defined in Equation 21.81 in the Theory Guide.

Linear stability theory determines a range of permissible values for the CFL (that is, the range of values for which a given numerical scheme will remain stable). When you specify a permissible CFL value, ANSYS Fluent will compute an appropriate time step using Equation 21.81 in the Theory Guide. In general, taking larger time steps leads to faster convergence, so it is advantageous to set the CFL as large as possible (within the permissible range).

The stability limits of the density-based implicit and explicit formulations are significantly different. The explicit formulation has a more limited range and requires lower CFL settings than does the density-based implicit formulation. Appropriate choices of CFL for the two formulations are discussed below.

28.4.1.1. Courant Numbers for the Density-Based Explicit Formulation

Linear stability analysis shows that the maximum allowable CFL for the multi-stage scheme used in the density-based explicit formulation will depend on the number of stages used and how often the dissipation and viscous terms are updated (see Changing the Multi-Stage Scheme (p. 1588)). But in general, you can assume that the multi-stage scheme is stable for Courant numbers up to 2.5. This stability limit is often lower in practice because of nonlinearities in the governing equations.

The default CFL for the density-based explicit formulation is 1.0, but you may be able to increase it for some 2D problems. You should generally not use a value higher than 2.0.

If your solution is diverging, that is, if residuals are rising very rapidly, and your problem is properly set up and initialized, this is usually a good sign that the Courant number must be lowered. Depending on the severity of the startup conditions, you may need to decrease the CFL to a value as low as 0.1 to 0.5 to get started. Once the startup transients are reduced you can start increasing the Courant number again.

28.4.1.2. Courant Numbers for the Density-Based Implicit Formulation

Linear stability theory shows that the density-based implicit formulation is unconditionally stable. However, as with the explicit formulation, nonlinearities in the governing equations will often limit stability.

The default CFL for the density-based implicit formulation is 5.0. It is often possible to increase the CFL to 10, 20, 100, or even higher, depending on the complexity of your problem. You may find that a lower CFL is required during startup (when changes in the solution are highly nonlinear), but it can be increased as the solution progresses.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

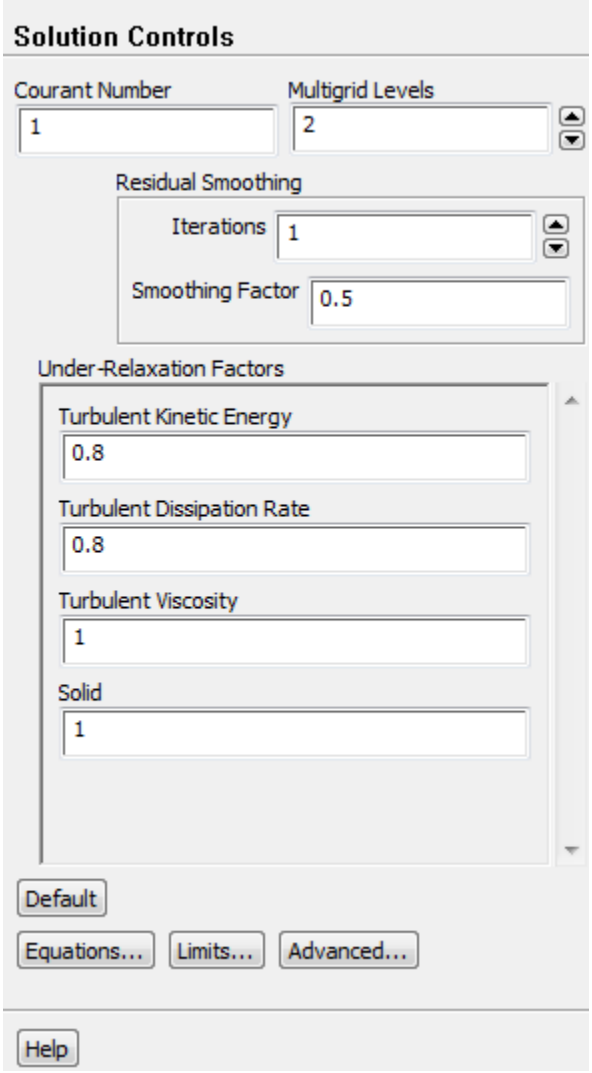
The coupled AMG solver has the capability to detect divergence of the multigrid cycles within a given iteration. If this happens, it will automatically reduce the CFL and perform the iteration again, and a message will be printed to the screen. Five attempts are made to complete the iteration successfully. Upon successful completion of the current iteration the CFL is returned to its original value and the iteration procedure proceeds as required.

28.4.1.3. User Inputs

The Courant number is set in the Solution Controls Task Page (p. 2508) (Figure 28.7: The Solution Controls Task Page for the Density-Based Explicit Formulation (p. 1572)).

Solution → Controls

Figure 28.7: The Solution Controls Task Page for the Density-Based Explicit Formulation



Enter the value for **Courant Number**.

When you select **Explicit** from the **Formulation** drop-down list in the Solution Methods Task Page (p. 2504), ANSYS Fluent will automatically set the **Courant Number** to 1; when you select **Implicit** from the **Formulation** drop-down list, the **Courant Number** will be changed to 5 automatically.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.4.2. Convective Flux Types

Three convective flux types exist when using the density-based solver:

- Roe flux-difference splitting (Roe-FDS)
- Advection Upstream Splitting Method (AUSM)
- Low diffusion Roe flux-difference splitting (Low Diffusion Roe-FDS)

Roe-FDS splits the fluxes in a manor that is consistent with their corresponding flux method eigenvalues. It is the default and is recommended for most cases.

AUSM provides exact resolution of contact and shock discontinuities and it is less susceptible to Carbuncle phenomena.

Low diffusion Roe-FDS is available in special circumstances when the LES viscous model is enabled and when time-implicit formulation is used in the density-based solvers. It reduces the dissipation in LES calculations. Low diffusion Roe-FDS should be used only for subsonic flows.

28.4.2.1. User Inputs

The convective fluxes are selected from the **Flux Type** drop-down list in the **Solution Methods** task page.

Solution → **Methods**

Select **Roe-FDS**, **AUSM**, or if the LES viscous model is enabled with the time-implicit formulation, **Low Diffusion Roe-FDS** will be available.

28.4.3. Convergence Acceleration for Stretched Meshes (CASM)

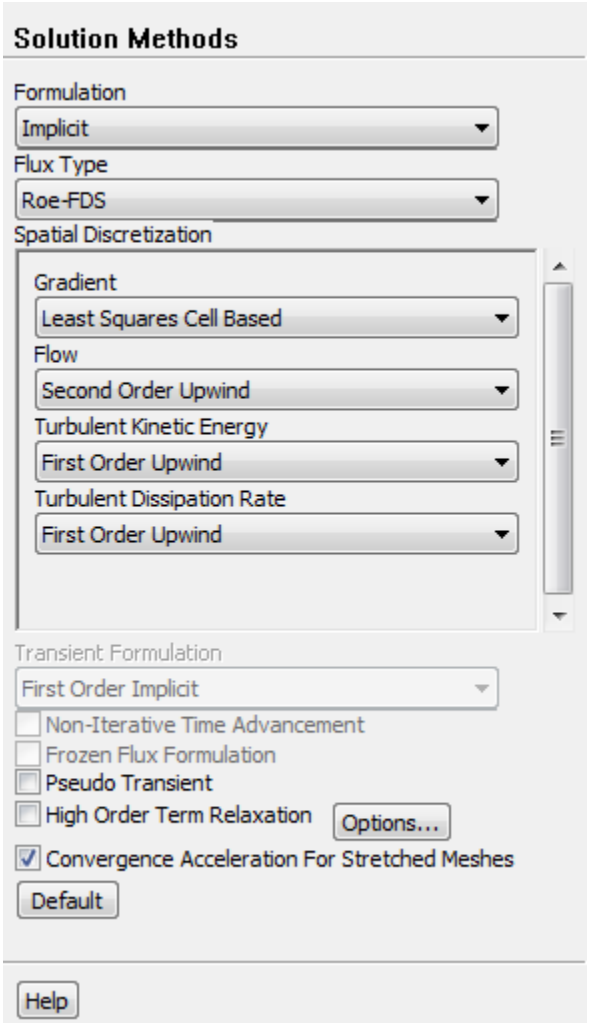
When using the density-based solver with the implicit solution formulation in steady-state you can accelerate the convergence of your solution on highly-stretched and anisotropic meshes (like the one used when modeling external aerodynamic problems) by selecting the **Convergence Acceleration For Stretched Meshes** in the **Solution Methods** task page. For further information and theoretical background on this solution acceleration option, see Convergence Acceleration for Stretched Meshes in the Theory Guide. The **Convergence Acceleration For Stretched Meshes** option provides an optimum solution convergence of the implicit solution method.

To apply convergence acceleration for stretched meshes, perform the following:

1. Specify the solver options by selecting **Density-Based** and **Steady** in the **General** task page.
2. Select **Implicit** from the **Formulation** drop-down list and enable **Convergence Acceleration For Stretched Meshes** in the **Solution Methods** task page (Figure 28.8: The Solution Methods Task Page for the Density-Based Implicit Formulation (p. 1574)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.8: The Solution Methods Task Page for the Density-Based Implicit Formulation



Extra settings for CASM can be set using the following text command:

`solve → set → convergence-acceleration-for-stretched-meshes/`

Enter `yes` in response to the `Use convergence acceleration for stretched meshes (CASM)?` question. You will also be asked for a cut-off on the CFL value multiplier. By default this value is set to 100. Typically, you do not need to adjust this value. But if convergence difficulties are encountered and reduction of the CFL value alone does not help improve convergence, then it is advisable to reduce this CFL multiplier cut-off to a lower value (for example from 100 to 50, 20 or 10).

The use of CASM can typically give a much faster convergence over the standard solution method. In general, when using CASM, you do not need to specify a very large CFL value as you do with the standard solution method. A CFL value between 5 and 10 is typically used for converging most flow problems. When the **Convergence Acceleration For Stretched Meshes** option is selected, the solver will run when appropriate with a variable local CFL value proportional to the cell aspect ratios. Therefore, when the cell aspect ratio nears unity (typically far from walls), the local cell CFL value will be the same as the value that you supplied. However, as the cell is stretched and the cell aspect ratio increases (near walls), the local cell CFL value will be multiplied by the cell aspect ratio value. This is true until the cell stretching is beyond the multiplier cut-off value specified using the text command. The proportional change in CFL value on highly stretched cells helps accelerate the solution especially on highly packed and stretched meshes like the one used in modeling external flow problems.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the cell aspect ratio is selected by default, the density based implicit solver will operate with an explicit relaxation of 0.5 which can be adjusted from the `Explicit underrelaxation value` entry in `solve → set → expert`

The convergence of the solution is mainly controlled by adjusting the CFL value. Therefore, if convergence problems are encountered, lowering the CFL value will help improve the convergence. Additional solution parameters to be adjusted for more conservative solution settings are:

1. lowering the density-based implicit solver explicit relaxation (`solve → set → expert`)
2. adjusting the CFL multiplier cut-off value to a lower value (`solve → set → convergence-acceleration-for-stretched-meshes/`)

This solution convergence method is very aggressive. Therefore it is of paramount importance to start with a good initial guess especially if you start with second order spatial discretization. To get a good starting solution with the guess you provide, you are advised to use the full multi-grid initialization method (see Full Multigrid (FMG) Initialization (p. 1595)).

Note

When selecting the **Convergence Acceleration For Stretched Meshes** option then the **Pseudo-Transient** solution method will not be available. You can either use **Convergence Acceleration For Stretched Meshes** or the **Pseudo-Transient** solution method. These two options cannot be used at the same time. Both methods help in obtaining faster convergence on anisotropic meshes. But one method requires that you enter a CFL value, while the other requires that you enter a pseudo-time step value to march the solution to convergence. It is up to you to select the method with which you are most comfortable.

Convergence Acceleration For Stretched Meshes shows an advantage over the standard solution method, particularly with stretched meshes with low Y+ values (near unity). The use of **Convergence Acceleration For Stretched Meshes** results in an alteration of the numerical dissipation of the selected flux scheme. This change may slightly impact the monitored loading level if compared with the solution obtained without the use of this option.

28.4.4. Specifying the Explicit Relaxation

To improve the convergence to steady-state for some flow cases when using the density-based implicit solver you can specify the explicit relaxation using the following text command:

`solve → set → expert`

Enter a value between `0` and `1` in response to the `Explicit relaxation value` prompt.

For more information about explicit relaxation, see Under-Relaxation of Variables in the Theory Guide.

28.4.5. Turning On FAS Multigrid

As discussed in Multigrid Method in the Theory Guide, FAS multigrid is an optional component of the density-based explicit formulation, while AMG multigrid is always on, by default for the density-based implicit formulation. Since nearly all density-based explicit calculations will benefit from the use of the FAS multigrid convergence accelerator, you should generally set a nonzero number of coarse grid levels before beginning the calculation. For most problems, this will be the only FAS multigrid parameter you

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

will need to set. Should you encounter convergence difficulties, consider applying one of the methods discussed in Setting FAS Multigrid Parameters (p. 1583).

Important

Note that you cannot use FAS multigrid with explicit time stepping (described in Temporal Discretization in the Theory Guide) because the coarse grid corrections will destroy the time accuracy of the fine grid solution.

28.4.5.1. Setting Coarse Grid Levels

As discussed in Full-Approximation Storage (FAS) Multigrid in the Theory Guide, FAS multigrid solves on successively coarser grids and then transfers corrections to the solution back up to the original fine grid, thereby increasing the propagation speed of the solution and speeding convergence. The most basic way you can control the multigrid solver is by specifying the number of coarse grid levels to be used.

As explained in Full-Approximation Storage (FAS) Multigrid in the Theory Guide, the coarse grid levels are formed by agglomerating a group of adjacent "fine" cells into a single "coarse" cell. The optimal number of grid levels is therefore problem-dependent. For most problems, you can start out with 4 or 5 levels. For large 3D problems, you may want to add more levels (although memory restrictions may prevent you from using more levels, since each coarse grid level requires additional memory). If you believe that multigrid is causing convergence trouble, you can decrease the number of levels.

If ANSYS Fluent reaches a coarse grid with one cell before creating as many levels as you requested, it will simply stop there. That is, if you request 5 levels, and level 4 has only 1 cell, ANSYS Fluent will create only 4 levels, since levels 4 and 5 would be the same.

To specify the number of grid levels you want, set the number of **Multigrid Levels** in the Solution Controls Task Page (p. 2508) (Figure 28.7: The Solution Controls Task Page for the Density-Based Explicit Formulation (p. 1572)).

Solution → **Controls**

You can also set the **Max Coarse Levels** under **FAS Multigrid Controls** in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513).

Changing the number of coarse grid levels in the **Solution Controls** task page will automatically update the number shown in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513).

Coarse grid levels are created when you first begin iterating. If you want to check how many cells are in each level, request one iteration and then click **Info** and select **Size** in the **Setting Up Domain** ribbon tab (**Mesh** group box) (as described in Mesh Size (p. 197)) to list the size of each grid level. If you are satisfied, you can continue the calculation; if not, you can change the number of coarse grid levels and check again.

For most problems, you will not need to modify any additional multigrid parameters once you have settled on an appropriate number of coarse grid levels. You can simply continue your calculation until convergence.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.4.5.2. Using Residual Smoothing to Increase the Courant Number

In the density-based explicit formulation, implicit residual smoothing (or averaging) is a technique that can be used to reduce the time step restriction of the solver, thereby allowing the Courant number to be increased. The implicit smoothing is implemented with an iterative Jacobi method, as described in Implicit Residual Smoothing in the Theory Guide. Solution Controls Task Page (p. 2508).

Solution → Controls

By default, the number of **Iterations** for **Residual Smoothing** is set to zero, indicating that residual smoothing is disabled. If you increase the **Iterations** counter to 1 or more, you can enter the **Smoothing Factor**. A smoothing factor of 0.5 with 2 passes of the Jacobi smoother is usually adequate to allow the Courant number to be doubled.

28.5. Setting Algebraic Multigrid Parameters

As mentioned earlier, in most cases the multigrid solver will not require any special attention from you. If, however, you have convergence difficulties or you want to minimize the overall solution time by using more aggressive settings, you can monitor the multigrid solver and modify the parameters to improve its performance. (The instructions below assume that you have already begun calculations, since there is no need to monitor the solver if you do not fit into one of the two categories above.)

To determine whether your convergence difficulties can be alleviated by modifying the multigrid settings, you will check if the requested residual reduction is obtained on each grid level. To minimize solution time, you will check to see if switching to a more powerful cycle will result in overall reduction of work by the solver.

By default, the flexible cycle is used for all equations except pressure correction, which uses a V cycle. Typically, for a flexible cycle only a few (5–10) relaxations will be performed at the finest level and no coarse levels will be visited. In some cases one or two coarse levels may be visited. If the maximum number of fine level relaxations is not sufficient, you may want to increase the maximum number (as described in Flexible Cycle Parameters (p. 1581)) or switch to a V cycle (as described in Specifying the Multigrid Cycle Type (p. 1578)).

In the pressure-based segregated algorithm, the pressure correction uses a V cycle by default. If the maximum number of cycles (30 by default) is not sufficient, you can switch to a W cycle (using the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513), as described in Specifying the Multigrid Cycle Type (p. 1578)). Note that for the parallel solver, efficiency may deteriorate with a W cycle.

If you are using the parallel solver, you can try increasing the maximum number of cycles by increasing the value of **Max Cycles** in the **Multigrid** tab, under **Fixed Cycle Parameters**.

In the pressure-based coupled algorithm and the density-based implicit formulation, there is no pressure correction. Instead, there is a flow correction, which by default uses the F cycle. The density-based explicit formulation uses the V cycle as the default flow correction.

Solution → Controls → Advanced...

For additional information, see the following sections:

28.5.1. Specifying the Multigrid Cycle Type
28.5.2. Setting the Termination and Residual Reduction Parameters
28.5.3. Setting the AMG Method and the Stabilization Method
28.5.4. Additional Algebraic Multigrid Parameters

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.5.5. Setting FAS Multigrid Parameters

28.5.1. Specifying the Multigrid Cycle Type

By default, the V cycle is used for the pressure equation in the pressure-based segregated algorithm and the flexible cycle is used for all other equations with the exception that the F cycle is used for energy. In the pressure-based coupled algorithm, the F cycle is the default for the coupled flow equations and for the energy equation. All other scalar equations use the flexible cycle by default. In the density-based implicit formulation, the F cycle is default for the flow correction. The V cycle is default for the flow correction in the density-based explicit formulation. For both density-based formulations the flexible cycle is used for the scalar equations. (See Multigrid Cycles in the Theory Guide for a description of these cycles.) To change the cycle type for an equation, you will use the top portion of the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)).

For each equation, you can choose **Flexible**, **V-Cycle**, **W-Cycle**, or **F-Cycle** in the adjacent drop-down list.

28.5.2. Setting the Termination and Residual Reduction Parameters

When you use the flexible cycle for an equation, you can control the multigrid performance by modifying the **Termination** and/or **Restriction** criteria for that equation at the top of the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)).

Solution → **Controls** → **Advanced...**

The **Restriction** criterion is the residual reduction tolerance, β in Equation 21.122 in the Theory Guide. This parameter dictates when a coarser grid level must be visited (due to insufficient improvement in the solution on the current level). With a larger value of β, coarse levels will be visited less often (and vice versa). The **Termination** criterion, α in Equation 21.123 in the Theory Guide, governs when the solver should return to a finer grid level (that is, when the residuals have improved sufficiently on the current level).

For the V, W, or F cycle, the **Termination** criterion determines whether or not another cycle should be performed on the finest (original) level. If the current residual on the finest level does not satisfy Equation 21.123 in the Theory Guide, and the maximum number of cycles has not been performed, ANSYS Fluent will perform another multigrid cycle. (The **Restriction** parameter is not used by the V, W, and F cycles.)

28.5.3. Setting the AMG Method and the Stabilization Method

You can use the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)) to choose between two AMG solvers: aggregative or selective. The aggregative AMG (AAMG) is the default solver that was used in previous versions of ANSYS Fluent. The selective AMG (SAMG) solver is available only for scalar equations, and is not available in parallel ANSYS Fluent. These two solvers differ in the way the grids are coarsened and in their interpolation method.

The AAMG solver [128] (p. 2894) builds coarse levels by grouping fine level cells to make coarse level cells, and uses piecewise constant interpolation. The SAMG solver [114] (p. 2893) builds coarse levels by

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

selecting some of the fine level cells for solution on the coarse level, and tries to approximate the use of linear interpolation.

Due to its use of more accurate interpolation, SAMG has a better convergence rate than AAMG but has a more expensive setup phase. For this reason, AAMG is usually faster if you are only converging one order of magnitude, while SAMG is faster if using a tight multigrid convergence tolerance. SAMG is a good choice for multiphase granular flow problems where a tight convergence tolerance on the pressure equation can be used to avoid volume imbalance errors in the volume fraction equations.

SAMG has advantages in solving problems with strongly varying (anisotropic) diffusive coefficients, which occurs in problems with porous media, conduction with anisotropic thermal conductivities, and multiphase problems. In some cases, using SAMG allows up to a 20% reduction in the number of external iterations for unsteady water-air turbulent flow in bubble columns, and allows increasing the VOF under-relaxation factor in phase separators from 0.2 (when used with AAMG) to 1.

In the **Multigrid** tab (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)), you can also choose a stabilization method. If desired, you can choose the bi-conjugate gradient stabilized method [9] (p. 2887) (**BCGSTAB**) option or recursive projection method [104] (p. 2892) (**RPM**) in order to improve the convergence of the linear solver. BCGSTAB can be preconditioned by any of the AMG solvers and provides stabilization for them whereas RPM stabilizes the AAMG solver.

ANSYS Fluent usually builds diagonally dominant matrices for the linear solver. However, this is not always possible. A linear system with highly dominant off-diagonal coefficients may occur during discretization of complex physical models such as multiphase cavitation. Using the **BCGSTAB** or **RPM** option in such cases can be helpful. In addition, the AMG convergence in parallel can be improved using the **BCGSTAB** option with AMG.

If you are using the pressure-based segregated solver and the flow is incompressible, an additional stabilization method for the algebraic multigrid solver will appear in the **Stabilization Method** drop-down list. This is the conjugate gradient method, or **CG** [9] (p. 2887) and will be available only for the pressure equation. This method is typically used in conjunction with an AMG preconditioner (any available AMG method). The CG formulation requires a symmetric system matrix. Such matrices result from the finite volume discretization of steady or transient elliptic operators, such as the pressure correction equation in the incompressible case. The CG method provides a useful extension to BCGSTAB and RPM, since it reduces the memory requirements and the number of floating point operations, especially when compared to BCGSTAB. In addition, in transient pressure-based segregated solvers, as typically used in LES and/or NITA simulations, the solution of the pressure correction equation constitutes a significant share of the overall computational effort.

28.5.4. Additional Algebraic Multigrid Parameters

There are several additional parameters that control the algebraic multigrid solver, but there will usually be no need to modify them. These additional scalar and coupled parameters are all contained in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)).

Solution → **Controls** → **Advanced...**

Important

When using the density-based explicit formulation or the pressure-based solver with any of the segregated algorithms, described in Pressure-Velocity Coupling in the Theory Guide and

Choosing the Pressure-Velocity Coupling Method (p. 1561), only **Scalar Parameters** are set in the **Multigrid** tab. If you use the density-based implicit or the pressure-based coupled algorithm, described in Coupled Algorithm in the Theory Guide, then you can set the **Coupled Parameters**.

28.5.4.1. Fixed Cycle Parameters

For the fixed (V, W, and F) multigrid cycles, you can control the number of pre- and post-relaxations (β_1 and β_3 in Multigrid Cycles in the Theory Guide). **Pre-Sweeps** sets the number of relaxations to perform before moving to a coarser level. **Post-Sweeps** sets the number to be performed after coarser level corrections have been applied. Normally, under **Scalar Parameters**, one post-relaxation is performed and no pre-relaxations are done (that is, $\beta_3=1$ and $\beta_1=0$), but in rare cases, you may need to increase the value of β_1 to 1 or 2. Under **Coupled Parameters**, three post-relaxations are performed by default with no pre-relaxations. If you are using the pressure-based coupled solver for a steady simulation with pseudo-transient enabled, three post-relaxations are performed under **Scalar Parameters** also.

Important

- If you are using AMG with V-cycle to solve an energy equation with a solid conduction model presented with anisotropic or very high conductivity coefficient, there is a possibility of divergence with a default post-relaxation sweep of 1. In such cases you should increase the post-relaxation sweep (to say 2) in the AMG section for better convergence when using the pressure-based segregated algorithms.
- It is recommended that you use the Fixed F-cycle for the energy equation when running parallel ANSYS Fluent.

28.5.4.2. Coarsening Parameters

For all multigrid cycle types, you can control the maximum number of coarse levels (**Max Coarse Levels** under **Scalar** or **Coupled Parameters**) that will be built by the multigrid solver.

Sets of coarser simultaneous equations are built until the maximum number of levels has been created, or the coarsest level has only 3 equations. Each level has about half as many unknowns as the previous level, so coarsening until there are only a few cells left will require about as much total coarse-level coefficient storage as was required on the fine mesh. Reducing the maximum coarse levels will reduce the memory requirements, but may require more iterations to achieve a converged solution. Setting **Max Coarse Levels** to 0 turns off the algebraic multigrid solver.

Another coarsening parameter you can control is the increase in coarseness on successive levels. The **Coarsen by** parameter specifies the number of fine grid cells that will be grouped together to create a coarse grid cell. The algorithm groups each cell with its strongest neighbor, then groups the cell and its strongest neighbor with the neighbor's strongest neighbor, continuing until the desired coarsening is achieved. Typical values for the scalar parameters are in the range from 2 to 10, with the default value of 2 for the Gauss-Seidel smoother giving the best performance, but also the greatest memory use. For coupled parameters and scalar parameters when using the pressure-based coupled solver with pseudo-transient enabled, the default values of 4 (for 2D) and 8 (for 3D) for the ILU smoother give the best

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

performance. You should not adjust this parameter unless you need to reduce the memory required to run a problem.

Important

Depending on the smoother type, Gauss-Seidel or ILU, the **Coarsen by** and **Post-Sweeps** settings should be changed as follows when selecting the non-default smoother type:

ILU
: **Post-Sweeps**=3 and **Coarsen by** = 8

Gauss-Seidel
: **Post-Sweeps**=1 and **Coarsen by** = 2

By default, a cell's strongest neighbor is identified based on the magnitude of its interaction with the cell in question. Alternatively, you can enable **Laplace Coarsening** under **Scalar Parameters** or **Coupled Parameters** in the **Multigrid** tab of the **Advanced Solution Controls** dialog box. The Laplace coarsening option will use Laplace coefficients to evaluate neighbor strength when grouping cells for coarsening. This may improve stability in some cases because the coarser levels will not change as the solution evolves. It may also reduce computation time, particularly at high core counts, because the coarse levels don't need to be recreated every iteration.

For coupled equations, a **Conservative Coarsening** AMG option is enabled by default. This option improves convergence for difficult problems by tuning multigrid coarsening based on coefficient strengths and, in parallel computations, the partitioning.

28.5.4.3. Smoother Types

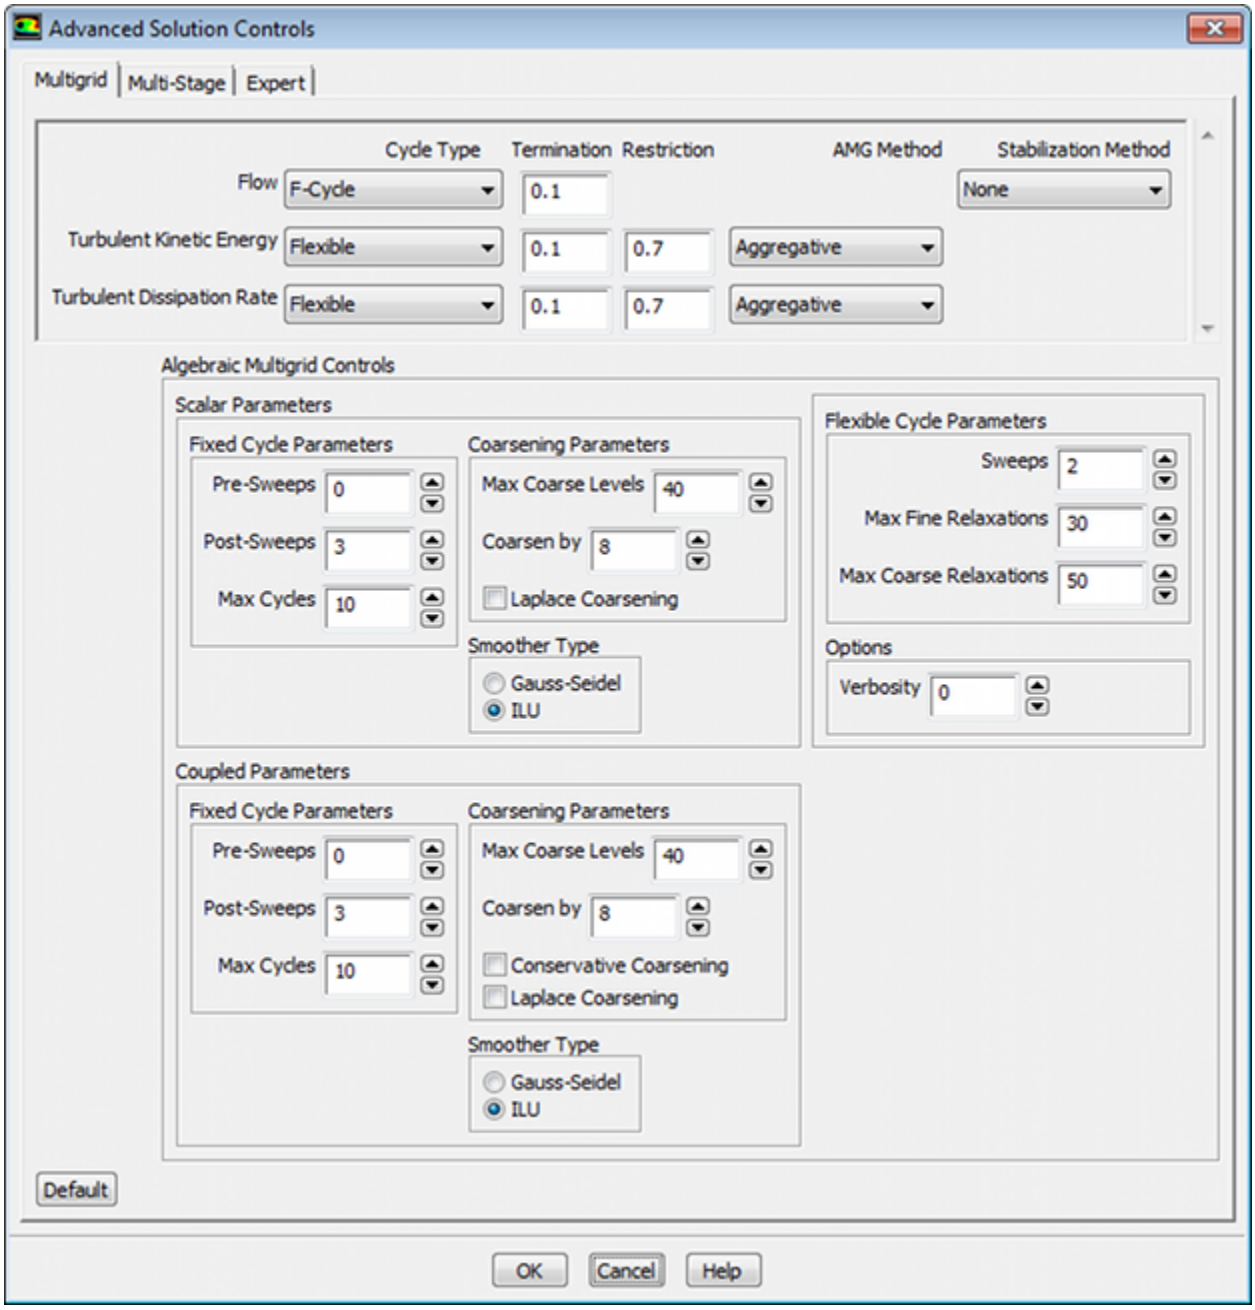
Two smoother types are available for scalar and coupled parameters. **Gauss-Seidel** is the simplest smoother type and is recommended when using the pressure-based segregated algorithm. **ILU** is more CPU intensive, but has better smoothing properties for block-coupled systems such as the pressure-based coupled solver and the density-based implicit formulation. The default scalar **Smoother Type** is **Gauss-Seidel**, while the coupled **Smoother Type** is **ILU**. The **ILU** smoother is also used for scalar equations when using the coupled solver with pseudo-transient enabled. For more information about the two smoother types, see The Coupled and Scalar AMG Solvers in the Theory Guide.

28.5.4.4. Flexible Cycle Parameters

To change the maximum number of relaxations, increase or decrease the value of **Max Fine Relaxations** or **Max Coarse Relaxations** in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.9: The Multigrid Tab for the Flexible Cycle (p. 1582)) under **Flexible Cycle Parameters**.

Solution → **Controls** → **Advanced...**

Figure 28.9: The Multigrid Tab for the Flexible Cycle



28.5.4.5. Setting the Verbosity

The steps for monitoring the solver are as follows:

1. Set multigrid **Verbosity** to 1 or 2 in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513).

   Solution → **Controls** → **Advanced...**

2. Request a single iteration using the Run Calculation Task Page (p. 2537).

   Solution → **Run Calculation**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you set the verbosity to 2, the information printed in the ANSYS Fluent console for each equation will include the following:

- equation name
- equation tolerance (computed by the solver using a normalization of the source vector)
- residual value after each fixed multigrid cycle or fine relaxation for the flexible cycle
- number of equations in each multigrid level, with the zeroth level being the original (finest-level) system of equations

Note that the residual printed at cycle or relaxation 0 is the initial residual before any multigrid cycles are performed.

When verbosity is set to 1, only the equation name, tolerance, and residuals are printed.

A portion of a sample printout is shown below:

```
pressure correction equation:
tol. 1.2668e-05
 0 2.5336e+00
 1 4.9778e-01
 2 2.5863e-01
 3 1.9387e-01

 multigrid levels:
 0 918
 1 426
 2 205
 3  97
 4  45
 5  21
 6  10
 7  4
```

28.5.4.6. Returning to the Default Multigrid Parameters

If you change the multigrid parameters, but you then want to return to ANSYS Fluent's default settings, you can click the **Default** button in the **Multigrid** tab. ANSYS Fluent will change all settings to the defaults, and the **Default** button will become the **Reset** button. To get your settings back again, you can click the **Reset** button.

28.5.5. Setting FAS Multigrid Parameters

For most calculations, you will not need to modify any FAS multigrid parameters once you have set the number of coarse grid levels. If, however, you encounter convergence difficulties, you may consider the following suggested procedures.

Important

Recall that FAS multigrid is used only by the density-based explicit formulation.

28.5.5.1. Combating Convergence Trouble

Some problems may approach convergence steadily at first, but then the residuals will level off and the solution will "get stuck." In some cases (for example, long thin ducts), this convergence trouble may

be due to multigrid's slow propagation of pressure information through the domain. In such cases, you should turn off multigrid by setting **Multigrid Levels** to 0 in the Solution Controls Task Page (p. 2508).

28.5.5.2. "Industrial-Strength" FAS Multigrid

In some cases, you may find that your problem is converging, but at an extremely slow rate. Such problems can often benefit from a more aggressive form of multigrid, which will speed up the propagation of the solution corrections. For such problems, you can try the "industrial-strength" multigrid settings.

Important

These settings are very aggressive and assume that the solution information passed through the multigrid levels is somewhat accurate. For this reason, you should only attempt the procedure described here after you have performed enough iterations that the solution is off to a good start. Using "industrial-strength" multigrid too early in the calculation process—when the solution is far from correct—will not help convergence and may cause the calculation to become unstable, as very incorrect values are propagated quickly to the original grid. Note also that while these multigrid settings will usually reduce the total number of iterations required to reach convergence, they will greatly increase the computation time for each multigrid cycle. Thus the solver will be performing fewer but longer iterations.

The strategy employed is as follows:

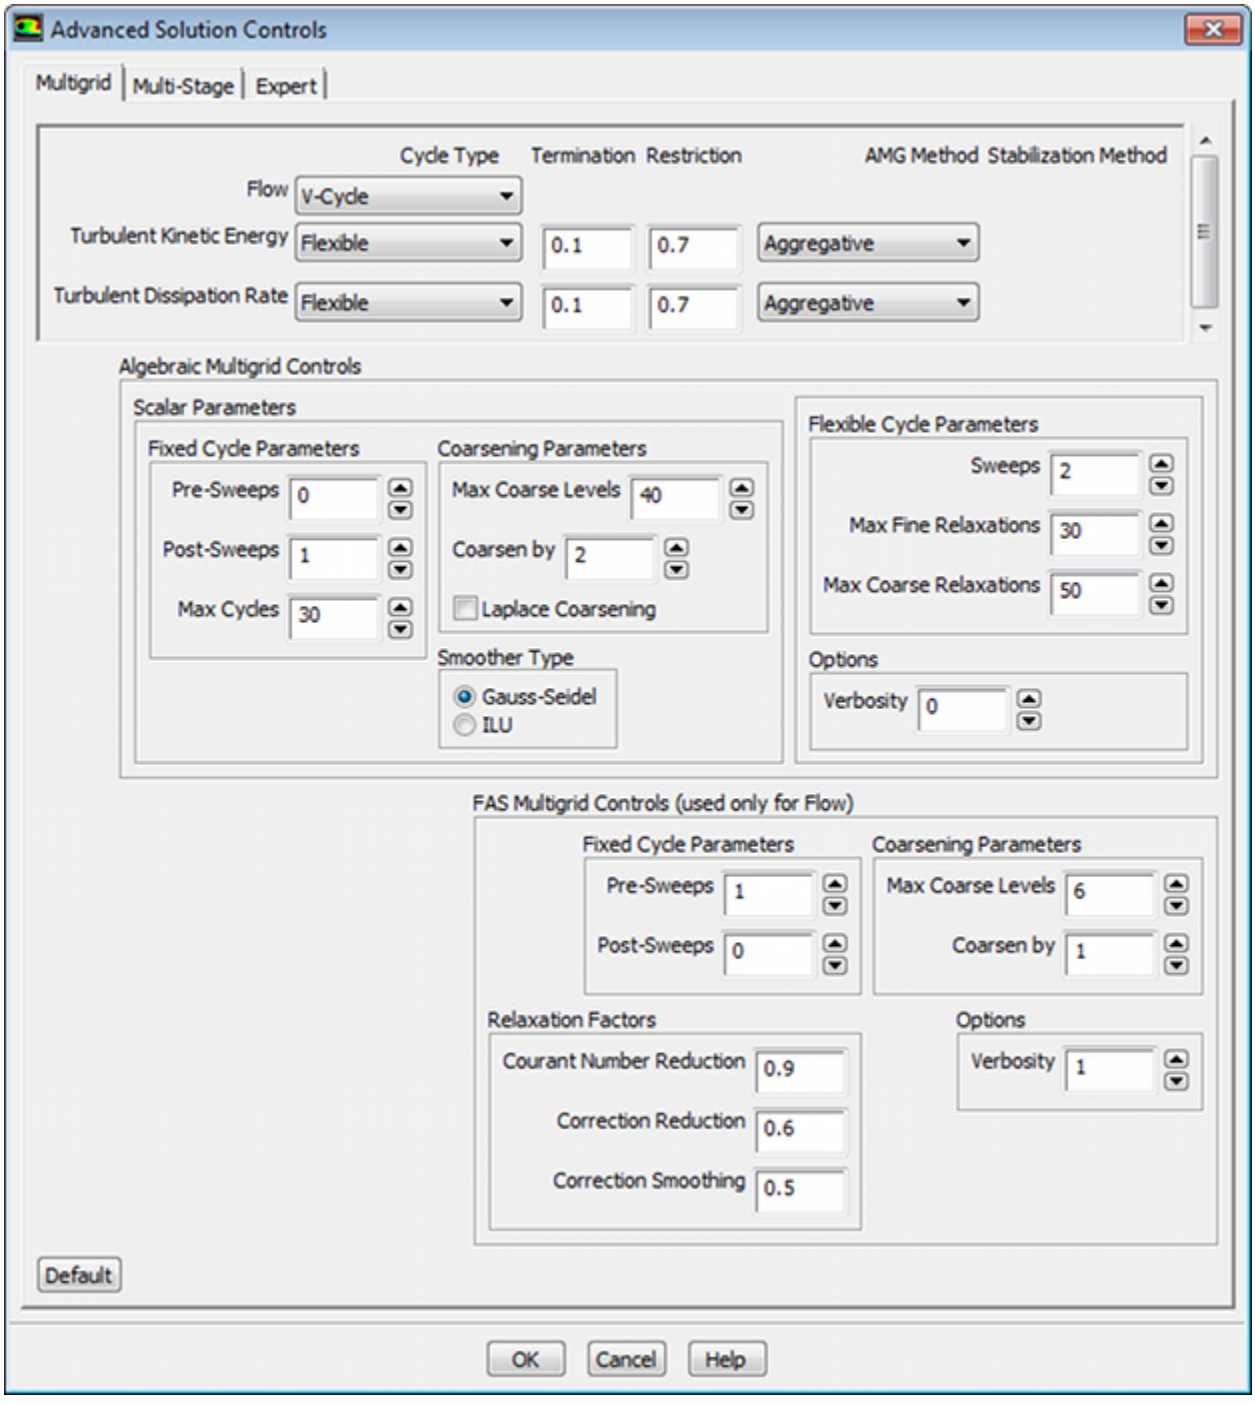
- Increase the number of iterations performed on each grid level before proceeding to a coarser level
- Increase the number of iterations performed on each grid level after returning from a coarser level
- Allow full correction transfer from one level to the next finer level, instead of transferring reduced values of the corrections
- Do not smooth the interpolated corrections when they are transferred from a coarser grid to a finer grid

You can set all of the parameters for this strategy under **FAS Multigrid Controls** in the **Multigrid** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.10: The Advanced Solution Controls Dialog Box (p. 1585)) and then continue the calculation.

Solution → **Controls** → **Advanced...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.10: The Advanced Solution Controls Dialog Box



Increasing the number of iterations performed on each grid level before proceeding to a coarser level (the value of β_1 described in Multigrid Cycles in the Theory Guide) will improve the solution passed from each finer grid level to the next coarser grid level. Try increasing the value of **Pre-Sweeps** (under **FAS Multigrid Controls**, *not* under **Algebraic Multigrid Controls**) to 10.

Increasing the number of iterations performed on each level after returning from a coarser level will improve the corrections passed from each coarser grid level to the next finer grid level. Errors introduced on the coarser grid levels can therefore be reduced before they are passed further up the grid hierarchy to the original grid. Try increasing the value of **Post-Sweeps** (under **FAS Multigrid Controls**, *not* under **Algebraic Multigrid Controls**) to 10.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By default, the full values of the multigrid corrections are not transferred from a coarser grid to a finer grid; only 60% of the value is transferred. This prevents large errors from transferring quickly up to the original grid and causing the calculation to become unstable. It also prevents a "good" solution from propagating quickly to the original grid. However, by increasing the **Correction Reduction** to 1, you can transfer the full values from coarser to finer grid levels, speeding the propagation of the solution and, usually, the convergence as well. The **Species Correction Reduction** sets the factor by which to reduce the magnitude of the species corrections to stabilize the multigrid calculation. This item appears only when species transport is being modeled.

When the corrections on a coarse grid are passed back to the next finer grid level, the values are, by default, interpolated and then smoothed. Disabling the smoothing so that the actual value in a coarse grid cell is assigned to the fine grid cells that comprise it can also aid convergence. To disable smoothing, set the **Correction Smoothing** to 0. Large discontinuities between cells will be smoothed out implicitly as a result of the additional **Post-Sweeps** performed.

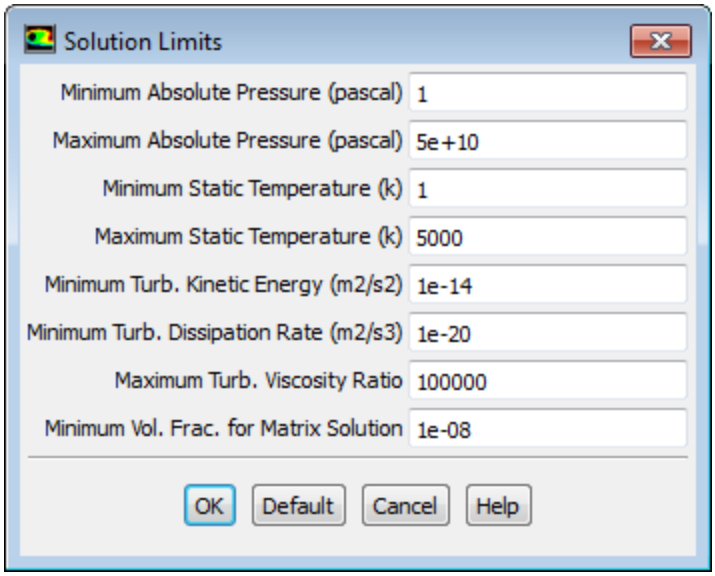
The **Courant Number Reduction** sets the factor by which to reduce the Courant number for coarse grid levels (that is, every level except the finest). Some reduction of time step (such as the default 0.9) is typically required because the stability limit cannot be determined as precisely on the irregularly shaped coarser grid cells.

28.6. Setting Solution Limits

In order to keep the solution stable under extreme conditions, ANSYS Fluent provides limits that keep the solution within an acceptable range. You can control these limits with the Solution Limits Dialog Box (p. 2511) (Figure 28.11: The Solution Limits Dialog Box (p. 1586)).

Solution → Controls → Limits...

Figure 28.11: The Solution Limits Dialog Box



Fluent applies limiting values for pressure, static temperature, and turbulence quantities. Fluent also applies a minimum volume fraction for the matrix solution in Eulerian multiphase simulations run on a double-precision solver. The purpose of these limits is to keep the absolute pressure or static temperature from becoming zero, negative, or excessively large during the calculation, and to keep the turbu-

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

lence quantities from becoming excessive. The purpose of the minimum volume fraction is to avoid singularity of the solution matrix when the volume fraction tends to zero.

Typically, you will not need to change the default solution limits. If pressure, temperature, or turbulence quantities are being reset to the limiting value repeatedly (as indicated by the appropriate warning messages in the console), you should check the dimensions, boundary conditions, and properties to be sure that the problem is set up correctly and try to determine why the variable in question is getting so close to zero or so large. You can use the "marking" feature (used to mark cells for adaption) to identify which cells have a value equal to the limit. (Use the Iso-Value Adaption Dialog Box (p. 2722), as described in Isovalue Adaption (p. 1691).) In very rare cases, you may need to change the solution limits, but only do so if you are sure that you understand the reason for the solver's unusual behavior. For example, you may know that the temperature in your domain will exceed 5000 K. Be sure that any temperature-dependent properties are appropriately defined for high temperatures if you increase the maximum temperature limit. Another rare example is when the actual volume fraction in the domain needs to go below a safe limit of 1e-08, such as in nucleation and dispersion of very low amounts of contaminants in a system. By reducing this limit you may encounter instability problems.

Important

The absolute pressure limit is enforced only for fluid materials that are modeled using the ideal-gas or one of the real-gas-* density methods.

For materials that use the compressible-liquid or a user-defined compressible fluid (liquid or gas) density method, a pressure limit is used to ensure that the density remains positive, but the actual pressure value itself is not limited.

For additional information, see the following sections:

28.6.1. Limiting the Values of Solution Variables
28.6.2. Adjusting the Positivity Rate Limit
28.6.3. Resetting Solution Limits

28.6.1. Limiting the Values of Solution Variables

The limiting minimum and maximum values for absolute pressure are shown in the **Minimum** and **Maximum Absolute Pressure** fields. If the ANSYS Fluent calculation predicts a value less than the **Minimum Absolute Pressure** or greater than the **Maximum Absolute Pressure**, the corresponding limiting value will be used instead. Similarly, the **Minimum** and **Maximum Temperature** are limiting values for energy calculations.

The **Minimum Turb. Kinetic Energy**, **Minimum Turb. Dissipation Rate**, and the **Maximum Turb. Viscosity Ratio** are limiting values for turbulent calculations. If the calculation predicts a value for k or ε that is less than the appropriate limiting value (that is, **Minimum Turb. Kinetic Energy** or **Minimum Turb. Dissipation Rate**, respectively), then the limiting value will be used instead. For the viscosity ratio limit, ANSYS Fluent uses the limiting maximum value of turbulent viscosity ($C_\mu k^2 / \varepsilon$) in the flow field relative to the laminar viscosity. If the ratio calculated by ANSYS Fluent exceeds the limiting value, the ratio is set to the limiting value by limiting ε to the necessary value.

For Eulerian multiphase simulations run on a double-precision solver, if the ANSYS Fluent calculation predicts a volume fraction value less than the **Minimum Vol. Frac. for Matrix Solution**, the limiting value will be used instead in the matrix solution.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.6.2. Adjusting the Positivity Rate Limit

In ANSYS Fluent's density-based solver, the rate of reduction of temperature is controlled by the **Positivity Rate Limit**. The default value of 0.2, for example, means that temperature is not allowed to decrease by more than 20% of its previous value from one iteration to the next. If the temperature change exceeds this limit, the time step in that cell is reduced to bring the change back into range and a "time step reduced" warning is printed. (This reduced time step will be used for the solution of all variables in the cell, not just for temperature.) Rapid reduction of temperature is an indication that the temperature may become negative. Repeated "time step reduced" warnings should alert you that something is wrong in your problem setup. (If the warning messages stop appearing, the calculation may have "recovered" from the time-step reduction.)

Important

For high-speed flow, if your solution is diverging particularly for the energy equation, then lowering this limit to 0.05 or 0.02 might help in overcoming divergence.

28.6.3. Resetting Solution Limits

If you change and save the value of one of the solution limits, but you then want to return to the default limits set by ANSYS Fluent, you can reopen the Solution Limits Dialog Box (p. 2511) and click the **Default** button. ANSYS Fluent will change the values to the defaults and the **Default** button will become the **Reset** button. To get your values back again, you can click the **Reset** button.

28.7. Setting Multi-Stage Time-Stepping Parameters

The most common parameter you will change to control the multi-stage time-stepping scheme is the Courant number. Instructions for modifying the Courant number are presented in Changing the Courant Number (p. 1571). The **Multi-Stage** tab is accessible from the **Advanced Solution Controls** dialog box when using the density-based explicit formulation.

For additional information, see the following section:
28.7.1. Changing the Multi-Stage Scheme

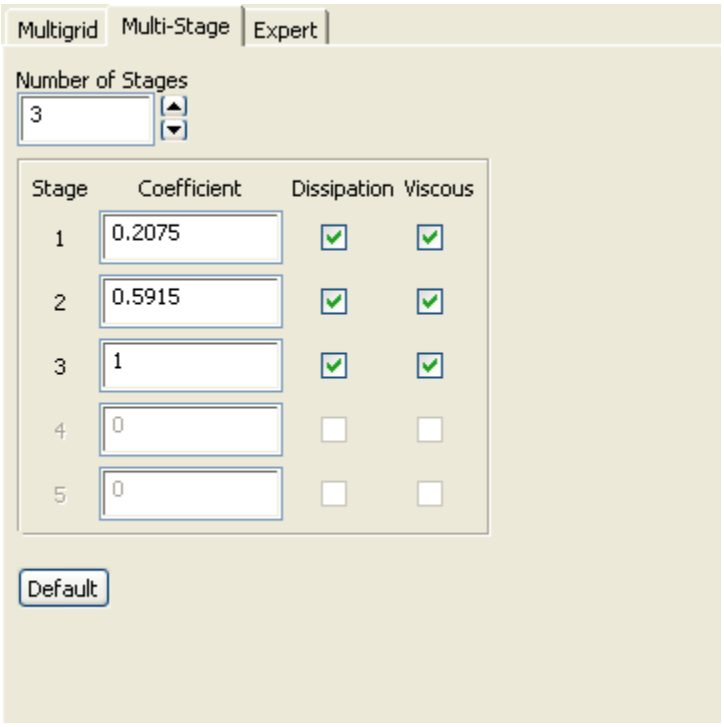
28.7.1. Changing the Multi-Stage Scheme

It is possible to make several changes to the multi-stage time-stepping scheme itself. You can change the number of stages and set a new multi-stage coefficient for each stage. You can also control whether or not dissipation and viscous stresses are updated at each stage. These changes are made in the **Multi-Stage** tab in the Advanced Solution Controls Dialog Box (p. 2513) (Figure 28.12: The Multi-Stage Tab (p. 1589)).

Solution → **Controls** **Advanced...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.12: The Multi-Stage Tab



Important

You should not attempt to make changes to ANSYS Fluent's multi-stage scheme unless you are very familiar with multi-stage schemes and are interested in trying a different scheme found in the literature.

28.7.1.1. Changing the Coefficients and Number of Stages

By default, the ANSYS Fluent multi-stage scheme uses 3 stages for steady-state solutions with coefficients of 0.2075, 0.5915, and 1.0, and 4 stages for unsteady solutions with coefficients of 0.25, 0.3333, 0.5, and 1.0. You can decrease or increase the number of stages using the arrow buttons for **Number of Stages** in the **Multi-Stage** tab. (If you want to increase the number of stages beyond five, you will need to use the text-interface command `solve/set/multi-stage`.)

For each stage, you can modify the **Coefficient**. Coefficients must be greater than 0 and less than 1. The final stage should always have a coefficient of 1.

28.7.1.2. Controlling Updates to Dissipation and Viscous Stresses

For each stage, you can indicate whether or not artificial dissipation and viscous stresses are evaluated. If a **Dissipation** box is selected for a particular stage, artificial dissipation will be updated on that stage. If not selected, artificial dissipation will remain "frozen" at the value of the previous stage. If a **Viscous** box is selected for a particular stage, viscous stresses will be updated on that stage. If not selected, viscous stresses will remain "frozen" at the value of the previous stage. Viscous stresses should always be computed on the first stage, and successive evaluations will increase the "robustness" of the solution process, but will also increase the expense (that is, increase the CPU time per iteration). For steady problems, the final solution is independent of the stages on which viscous stresses are updated.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.7.1.3. Resetting the Multi-Stage Parameters

If you change the multi-stage parameters, but you then want to return to the default scheme set by ANSYS Fluent, you can click the **Default** button in the **Multi-Stage** tab in the Advanced Solution Controls Dialog Box (p. 2513). ANSYS Fluent will change the values to the defaults and the **Default** button will become the **Reset** button. To get your values back again, you can click the **Reset** button.

28.8. Selecting Gradient Limiters

The default gradient limiter in ANSYS Fluent is the **Standard** limiter. Each of the limiters is described in detail in Gradient Limiters in the Theory Guide. The gradient limiters are accessible from the **Expert** tab in the **Advanced Solution Controls** dialog box.

Solution → **Controls** **Advanced...**

You can select **Standard**, **Multidimensional**, or **Differentiable** from the **Spatial Discretization Limiter Type** drop-down list.

Each of these options can also be accessed by typing the following text command:

`solve` → `set` → `slope-limiter-set`

Choose from the following options:

Criterion	Type
0	Default (TVD) slope limiter
1	Multidimensional (TVD) slope limiter
2	Differentiable slope limiter

Note that the `Default(TVD) slope limiter` in the TUI is equivalent to the **Standard** option in the GUI.

For each of the gradient limiter methods, ANSYS Fluent provides two limiting directions:

- **Cell to Face Limiting** is where the limited value of the reconstruction gradient is determined at cell face centers. This is the default method.
- **Cell to Cell Limiting** is where the limited value of the reconstruction gradient is determined along a scaled line between two adjacent cell centroids. On an orthogonal mesh (or when cell-to-cell direction is parallel to face area direction) this method becomes equivalent to the default cell to face method. For smooth field variation, cell to cell limiting may provide less numerical dissipation on meshes with skewed cells.

ANSYS Fluent also provides the option to apply a limiter filter to the **Standard** and **Differentiable** limiters. The purpose of the limiter filter is to maintain higher-order accuracy for the main flow variables. It suppresses limiter intervention arising from small numerical noise, while maintaining limiter control when there are actual discontinuities or large gradients in the solution (such as at shocks, boundary layers, and so on). The limiter filter can also help in improving the apparent convergence of the solution residual.

To use the limiter filter enable **Apply Limiter Filter**. When the limiter filter is turned on, then by default the filter mechanism is applied to the main flow and turbulent variables only. The filter mechanism is based on comparing local cell changes to average global domain changes of a particular flow variable.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

When the local changes are very small compared to the average global changes, then the limiter intervention will be suppressed.

Note

The limiter filter is not available when using the **Multidimensional** limiter.

28.9. Initializing the Solution

Before starting your CFD simulation, you must provide ANSYS Fluent with an initial "guess" for the solution flow field. In many cases, you must take extra care to provide an initial solution that will allow the desired final solution to be attained. A real-life supersonic wind tunnel, for example, will not "start" if the back pressure is simply lowered to its operating value; the flow will choke at the tunnel throat and will not transition to supersonic. The same holds true for a numerical simulation: the flow must be initialized to a supersonic flow or it will simply choke and remain subsonic.

There are two methods for initializing the solution:

- Initialize the entire flow field (in all cells). Three methods are available:
  - Standard initialization (see Initializing the Entire Flow Field Using Standard Initialization (p. 1591))
  - FMG initialization (see Full Multigrid (FMG) Initialization (p. 1595))
  - Hybrid initialization (see Hybrid Initialization (p. 1597))
- Patch values or functions for selected flow variables in selected cell zones or "registers" of cells. (Registers are created with the same functions that are used to mark cells for adaption.)

Important

Before patching initial values in selected cells, you must first initialize the entire flow field. You can then patch the new values over the initialized values for selected variables.

For additional information, see the following sections:
28.9.1. Initializing the Entire Flow Field Using Standard Initialization
28.9.2. Patching Values in Selected Cells

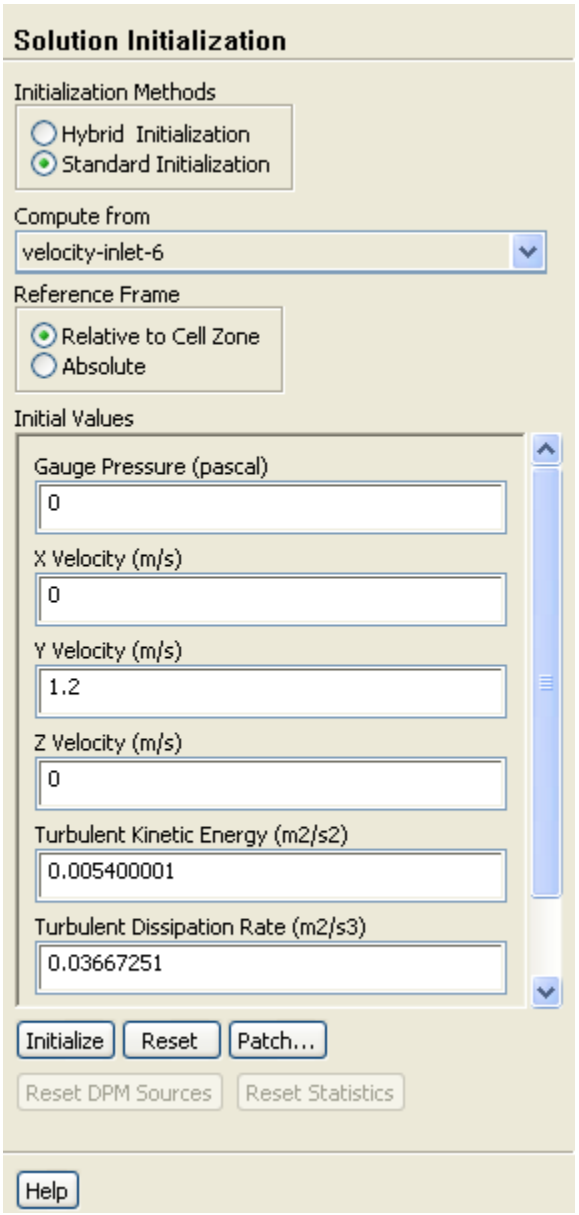
28.9.1. Initializing the Entire Flow Field Using Standard Initialization

Before you start your calculations *or* patch initial values for selected variables in selected cells (Patching Values in Selected Cells (p. 1593)) you must initialize the flow field in the entire domain. The Solution Initialization Task Page (p. 2520) (Figure 28.13: The Solution Initialization Task Page (p. 1592)) allows you to set initial values for the flow variables and initialize the solution using these values.

Solution → **Initialization**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.13: The Solution Initialization Task Page



You can compute the values from information in a specified zone, enter them manually, or have the solver compute average values based on all zones. You can also indicate whether the specified values for velocities are absolute or relative to the velocity in each cell zone. The steps for standard initialization are as follows:

1. Select **Standard Initialization** as the **Initialization Method**.

2. Set the initial values:

   - To initialize the flow field using the values set for a particular zone, select the zone name in the **Compute from** drop-down list. All values under the **Initial Values** heading will automatically be computed and updated based on the conditions defined at the selected zone.

   - To initialize the flow field using computed average values, select **all-zones** in the **Compute from** drop-down list. ANSYS Fluent will compute and update the **Initial Values** based on the conditions defined at all boundary zones.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want to change one or more of the values, you can enter new values manually in the fields next to the appropriate variables. If you prefer to enter all values manually, you can do so without selecting a zone in the **Compute from** list. For species transport cases with a single phase flow, you can select boundary species to be displayed in the list using the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)) that can be accessed by clicking **Species** in the **Solution Initialization** task page.

3. If your problem involves moving reference frames or sliding meshes, indicate whether the initial velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone** under **Reference Frame**. (If no zone motion occurs in the problem, the two options are equivalent.) The default reference frame for velocity initialization in ANSYS Fluent is relative. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.

4. After you are satisfied with the **Initial Values** displayed in the task page, you can click the **Initialize** button to initialize the flow field. If solution data already exist (that is, if you have already performed some calculations or initialized the solution), you must confirm that it is OK to overwrite those data.

28.9.1.1. Saving and Resetting Initial Values

When you initialize the solution by clicking on **Initialize**, the initial values will also be saved; should you need to reinitialize the solution later, you will find the correct values in the task page when you reopen it.

If you accidentally select the wrong zone from the **Compute from** list or manually set a value incorrectly, you can use the **Reset** button to reset all fields to their "saved" values.

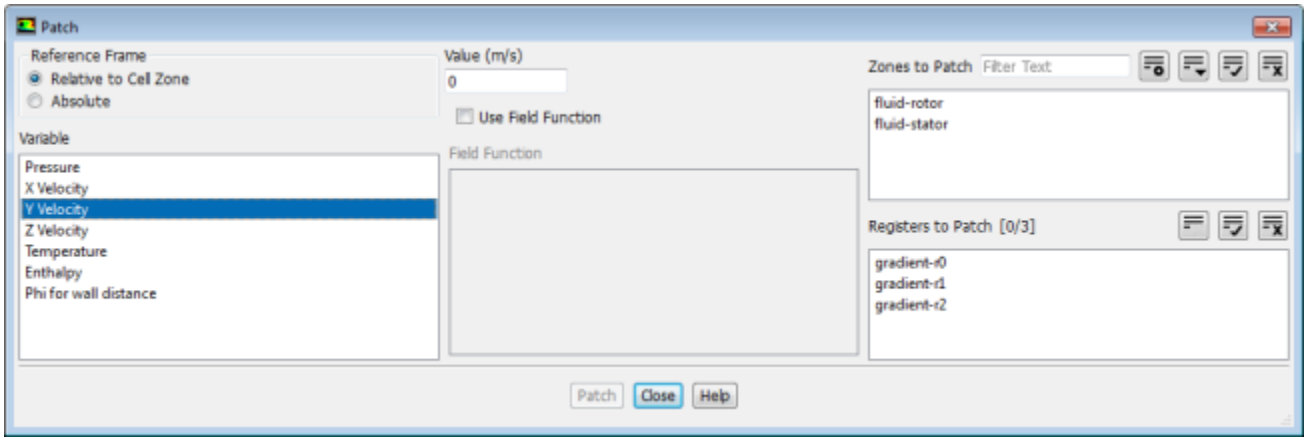
28.9.2. Patching Values in Selected Cells

Once you have initialized (or calculated) the entire flow field, you may patch different values for particular variables into different cells. If you have multiple fluid zones, for example, you may want to patch a different temperature in each one. You can also choose to patch a custom field function (defined using the Custom Field Function Calculator Dialog Box (p. 2683)) instead of a constant value. If you are patching velocities, you can indicate whether the specified values are absolute velocities or velocities relative to the cell zone's velocity. All patching operations are performed with the Patch Dialog Box (p. 2522) (Figure 28.14: The Patch Dialog Box (p. 1594)).

Solution → **Initialization** **Patch...**

Solution → **Initialization** → **Patch...**

Figure 28.14: The Patch Dialog Box



1. Select the variable to be patched in the **Variable** list.

   Note

   For species transport cases with a single phase flow, you can select boundary species to be displayed in the **Variable** list using the **Select Boundary Species** dialog box (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)) that can be accessed by clicking the **Species** button in the **Solution Initialization** task page.

2. In the **Zones to Patch** and/or **Registers to Patch** lists, choose the zone(s) and/or register(s) for which you want to patch a value for the selected variable.

   Important

   When a shell zone has been created (that is, by enabling shell conduction for a wall and running the calculation), the name of the shell zone will be listed in the **Zones to Patch** list as **shell :** <*wall-name*>, where <*wall-name*> is the name of the wall in which shell conduction has been enabled. Only temperature can be patched into the cells of a shell, and the same value or field function will be patched into every layer of the shell.

3. If you want to patch a constant value, simply enter that value in the **Value** field. If you want to patch a previously-defined field function, enable the **Use Field Function** option and select the appropriate function in the **Field Function** list.

4. If you selected a velocity in the **Variable** list, and your problem involves moving reference frames or sliding meshes, indicate whether the patched velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone** under **Reference Frame**. (If no zone motion occurs in the problem, the two options are equivalent.) The default reference frame for velocity patching in ANSYS Fluent is relative. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Click the **Patch** button to update the flow-field data. (Note that patching will have no effect on the iteration or time-step count.)

Important

If you apply a patch when setting up an ANSYS Fluent simulation from ANSYS Workbench, the patch will not be automatically performed during future automatic solution updates from Workbench. If you need to apply the patch each time the solution is updated from Workbench, you can do so by adding the text command `/solve/patch` (with appropriate arguments) to the **Original Settings** command list in the **Case Modification** tab of the **Automatic Solution Initialization and Case Modification** dialog box. See Automatic Initialization of the Solution and Case Modification (p. 1642) in this manual and Case Modification Strategies with Fluent and Workbench in the Fluent in Workbench User's Guide for more details on automatic case modification.

28.9.2.1. Using Registers

The ability to patch values in cell registers gives you the flexibility to patch different values within a single cell zone. For example, you may want to patch a certain value for temperature only in fluid cells with a particular range of concentrations for one species. You can create a cell register (basically a list of cells) using the functions that are used to mark cells for adaption. These functions allow you to mark cells based on physical location, cell volume, gradient or isovalue of a particular variable, and other parameters. See Adapting the Mesh (p. 1681) for information about marking cells for adaption. Manipulating Adaption Registers (p. 1701) provides information about manipulating different registers to create new ones. Once you have created a register, you can patch values in it as described above.

28.9.2.2. Using Field Functions

By defining your own field function using the Custom Field Function Calculator Dialog Box (p. 2683), you can patch a non-constant value in selected cells. For example, you may want to patch varying species mass fractions throughout a fluid region. To use this feature, simply create the function as described in Custom Field Functions (p. 2003), and then perform the function-patching operation in the Patch Dialog Box (p. 2522), as described above.

28.9.2.3. Using Patching Later in the Solution Process

Since patching affects only the variables for which you choose to change the value, leaving the rest of the flow field intact, you can use it later in the solution process without losing calculated data. (Initialization, on the other hand, resets all data to the initial values). For example, you might want to start a combustion calculation from a cold-flow solution. You can simply read in (or calculate) the cold-flow data, patch a high temperature in the appropriate cells, and continue the calculation.

Patching can also be useful when you are solving a problem using a step-by-step technique, as described in Step-by-Step Solution Processes (p. 1669).

28.10. Full Multigrid (FMG) Initialization

For many complex flow problems such as those found in rotating machinery, or flows in expanding or spiral ducts, flow convergence can be accelerated if a better initial solution is used at the start of the calculation. The Full Multigrid initialization (FMG initialization) can provide this initial and approximate solution at a minimum cost to the overall computational expense.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For more information about FMG initialization, see Overview of FMG Initialization in the Theory Guide.

For additional information, see the following sections:
28.10.1. Steps in Using FMG Initialization
28.10.2. Convergence Strategies for FMG Initialization

28.10.1. Steps in Using FMG Initialization

You can access the FMG initialization procedure using the text user interface (TUI) once the standard flow initialization is performed (see Full-Approximation Storage (FAS) Multigrid in the Theory Guide) or if valid flow data is available (that is, through reading a data file).

To customize the FMG initialization, type the following command :

`solve` → `initialize` → `set-fmg-initialization`

You will be asked to enter:

- The number of multigrid levels for the FMG iteration (the default is 5).

  Important

  For small cases (100, 000 cells or less), it is recommended that you lower the number of multigrid levels to 3 or 4.

- For each level of multigrid, you will be asked to enter the residual reduction (the default value is `0.001`), and the number of cycles per level (the defaults at each level are `10`, `10`, `50`, `100`, `500`, and `500`). In general, you should perform more iterations on coarse levels than fine levels. Level 0 is the finest level, which represents the original mesh.
- FMG iteration Courant-number (the default is `0.75`). This will be the CFL value that the FAS multigrid will use for the FMG initialization.
- Enabling verbose mode (the default is `no`). By enabling this option, you will be able to monitor the convergence at each level.

  Important

  If you do not customize the FMG settings, then the default values will be used.

To perform the FMG initialization, type the following command :

`solve` → `initialize` → `fmg-initialization`

When you are prompted to `Enable FMG initialization? [no]`, type `yes`.

When verbose mode is selected and the FMG initialization is being used, ANSYS Fluent will first output the multigrid level information followed by convergence history for the FAS multigrid cycle on each level. The normalized residual value is printed after ten FAS cycles or when the number of FAS cycles is reached. The output will indicate when convergence is reached on each level and when the solution is being interpolated to the next level.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.10.2. Convergence Strategies for FMG Initialization

When setting the FMG initialization parameters, you should consider performing more iterations on the coarse levels than on the fine levels. However, remember that the purpose of FMG initialization is to obtain a good initial solution at a low cost. You should try to avoid unreasonable convergence tolerance that will make the FMG initialization expensive.

Turn on the verbose mode to help you determine if the flow is converging as expected during the FMG iterations. If the solution is not converging to the desired tolerance, consider increasing the number of FAS multigrid cycles at each level. If the solution is diverging during the FAS cycles, then consider lowering the FMG iteration Courant number since the default value is probably too aggressive and is likely causing the solution to diverge.

For turbulent flows, it is very important to first perform standard initialization with proper and realistic values of the turbulence variables (for example k and ε). This can be done by computing the average values based on the conditions defined at the inflow boundary or at all boundary zones. Then, you can proceed with FMG initialization. Unrealistic initialization of turbulence variables may cause convergence difficulties during the first few iterations on the fine mesh, thereby nullifying the benefit of FMG initialization.

28.11. Hybrid Initialization

Hybrid initialization is yet another initialization method in ANSYS Fluent. The other initialization methods are standard initialization and FMG initialization. Hybrid initialization is a collection of recipes and boundary interpolation methods. It solves Laplace's equation to determine the velocity and pressure fields. All other variables, such as temperature, turbulence, species fractions, volume fractions, and so on, will be automatically patched based on domain averaged values or a particular interpolation recipe.

For more information about hybrid initialization, see Hybrid Initialization in the Theory Guide.

For additional information, see the following sections:
28.11.1. Steps in Using Hybrid Initialization
28.11.2. Solution Strategies for Hybrid Initialization

28.11.1. Steps in Using Hybrid Initialization

The default initialization method for single phase steady-state flows is the **Hybrid Initialization** method.

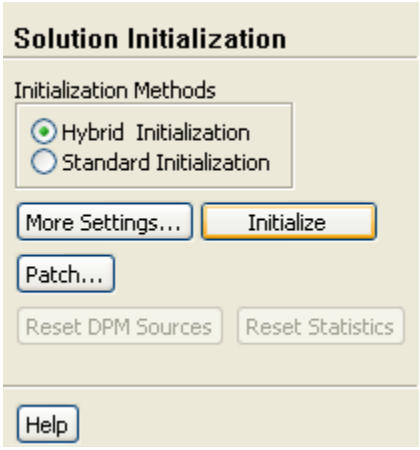
Note

For other flow types, such as multiphase or unsteady simulations, the default initialization method is the **Standard Initialization** method. However both initialization methods are available for use in all flow conditions and types.

To use **Hybrid Initialization**, go to the Solution Initialization Task Page (p. 2520) (Figure 28.15: The Solution Initialization Task Page for Hybrid Initialization (p. 1598)) where you will select **Hybrid Initialization**.

Solution → **Initialization**

Figure 28.15: The Solution Initialization Task Page for Hybrid Initialization

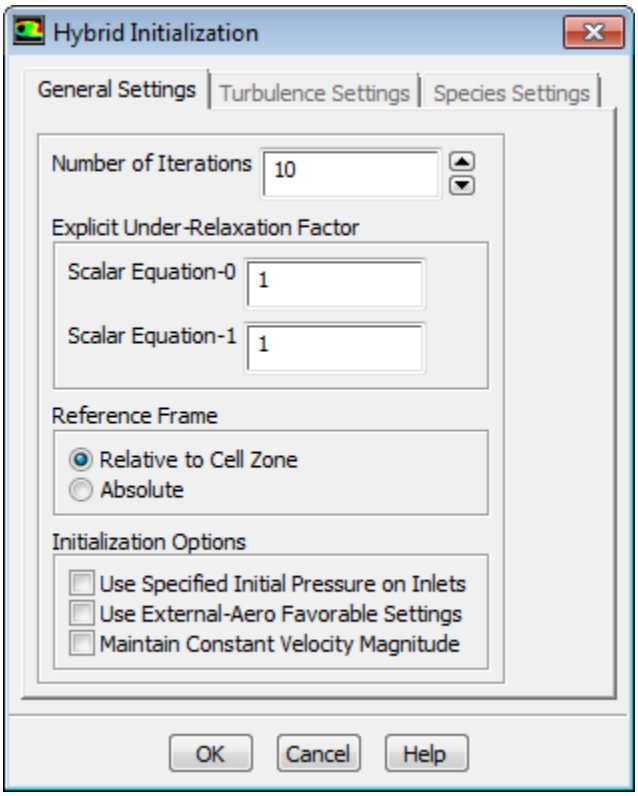


Note

In most cases, you need not do anything more than click the **Initialize** button. However, should you decide to modify the default settings for the hybrid initialization method, click **More Settings...**.

If you click **More Settings...**, the **Hybrid Initialization** dialog box (Figure 28.16: The Hybrid Initialization Dialog Box (p. 1598)) will open. A host of settings that control the **Hybrid Initialization** strategy will be available for you to adjust.

Figure 28.16: The Hybrid Initialization Dialog Box



You can make adjustments in three different areas:

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **General Settings** tab:

  – **Number of Iterations** uses a default value of 10. This is the number of iterations that will be performed while solving the Laplace equations to initialize the velocity and pressure. In general, you do not need to change the number of iterations. However, for complex and highly curved geometries, if the default number of iterations is not enough to reach the convergence tolerance of 1e-06 and the flow fields are not to your liking, then you may want to increase the number of iterations and re-initialize the flow.

  – **Explicit Under-Relaxation Factor** uses a default value of 1. This value will be used while solving the Laplace equation to initialize the velocity and pressure. In general, you do not need to change the explicit under-relaxation factor. However, for some cases, where the scalar residuals are oscillating and showing difficulty reaching the convergence tolerance of 1e-06, you may want to re-initialize the flow by reducing the under-relaxation factor. You may also want to increase the number of iterations to produce a smooth initialization field for the velocity and pressure.

  – **Reference Frame** is set to **Relative to Cell Zone** by default. If your problem involves moving reference frames or sliding meshes, indicate whether the initial velocities are absolute velocities or velocities relative to the motion of each cell zone by selecting **Absolute** or **Relative to Cell Zone**. If no zone motion occurs in the problem, the two options are equivalent. If the solution in most of your domain is rotating, using the relative option may be better than using the absolute option.

  – **Initialization Options** allows you to include the following options:

    → **Use Specified Initial Pressure on Inlets** if you want the specified pressure for **Supersonic/Initialization Gauge Pressure** at the inlet boundaries to be used for solving the Laplace equation for the pressure. Otherwise, ANSYS Fluent uses a predetermined recipe to determine the initial pressure field, as described in Hybrid Initialization of the Theory Guide.

    → **Use External-Aero Favorable Settings** if you want to have the velocity potential patched with a linear value to help accelerate convergence of **Scalar Equation–0** and to obtain a better guess of the velocity field for external-aero problems, such as flow over wings, airfoils, or automobiles.

    → **Maintain Constant Velocity Magnitude** if you want to use the flow direction obtained from solving the velocity potential (**Scalar Equation–0**), while maintaining a constant velocity magnitude throughout the computational domain. This option is helpful in some incompressible external flow problems, porous media problems, or if there are narrow channels where large undesirable velocities can be reached.

- **Turbulence Settings** tab uses by default the domain averaged values for the turbulence parameters. If you want to use variable turbulence parameters you can deselect the **Average Turbulent Parameters** check box. When this option is disabled, then it calculates the turbulent parameters, such as kinetic energy, dissipation energy, and so on, using local flow parameters.

- **Species Settings** tab will by default initialize secondary species with zero mass or mole fractions. If you want to specify the appropriate value for the species, you will need to enable **Specify Species Parameters**. Note that only the boundary species that you have selected in the **Select Boundary Species** dialog box appear in the list (see Figure 14.3: The Select Boundary Species Dialog Box (p. 966)). You can add or remove a species using the **Select Boundary Species** that can be accessed by clicking **Species** in the **Solution Initialization** task page.

28.11.2. Solution Strategies for Hybrid Initialization

In general, you do not need to make any extra adjustments to the hybrid initialization default settings. However, if the hybrid initialization is not producing the initial field to your liking, then you can play with the various options available in the **Hybrid Initialization** dialog box (described in Steps in Using

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Hybrid Initialization (p. 1597)), or you can also use the patching option in addition to the **Hybrid Initialization**. For example, if you are solving a user-defined scalar, then hybrid initialization will initialize them with a value of zero. However, you can specify the value with which you want to patch.

Note

You can also use a user-defined function to initialize the flow or certain flow variable in conjunction with hybrid initialization.

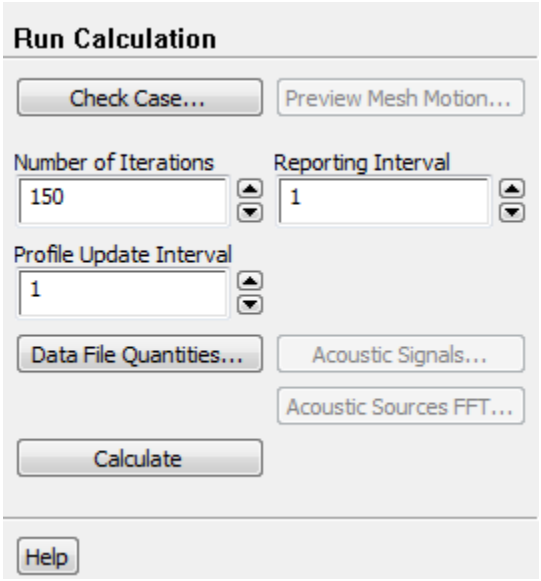
Standard Initialization is the recommended initialization method for porous media simulations. The default **Hybrid initialization** method does not account for the porous media properties, and depending on boundary conditions, may produce an unrealistic initial velocity field. For porous media simulations, the **Hybrid initialization** method can only be used with the **Maintain Constant Velocity Magnitude** option.

28.12. Performing Steady-State Calculations

For steady-state calculations, you will request the start of the solution process using the Run Calculation Task Page (p. 2537) (Figure 28.17: The Run Calculation Task Page (p. 1600)).

Solution → Run Calculation

Figure 28.17: The Run Calculation Task Page



Here, you will supply the number of additional iterations to be performed in the **Number of Iterations** field. (For unsteady calculation inputs, see User Inputs for Time-Dependent Problems (p. 1609)). If no calculations have been performed yet, ANSYS Fluent will begin calculations starting at iteration 1, using the initial solution. If you are starting from current solution data, ANSYS Fluent will begin at the last iteration performed, using the current solution data as its starting point.

By default, ANSYS Fluent will update the convergence monitors (described in Monitoring Solution Convergence (p. 1624)) after each iteration. If you increase the **Reporting Interval** from the default of 1 you can get reports less frequently. For example, if you set the **Reporting Interval** to 2, the monitors will print or plot reports at every other iteration. Note that the **Reporting Interval** also specifies how often ANSYS Fluent should check if the solution is converged. For example, if your solution converges

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

after 40 iterations, but your **Reporting Interval** is set to 50, ANSYS Fluent will continue the calculation for an extra 10 iterations before checking for (and finding) convergence.

When you click the **Calculate** button, ANSYS Fluent will begin to calculate. During iteration, a **Working** dialog box is displayed. Clicking the **Cancel** button or typing **Ctrl**+**c** in the ANSYS Fluent console will stop after the current iteration (in steady-state simulations) or the current time step (in transient simulations). If you are running a transient simulation and you want to interrupt the solution before the end of the current time step you can type **Ctrl**+**c** a second time. (See below for more details).

For additional information, see the following sections:

28.12.1. Updating UDF Profiles
28.12.2. Interrupting Iterations
28.12.3. Resetting Data

28.12.1. Updating UDF Profiles

If you have used a user-defined function (UDF) to define any boundary conditions you can control the frequency with which the function is updated by modifying the value of the **Profile Update Interval**. If **Profile Update Interval** is set to n, the function will be updated after every n iterations.

By default, the **Profile Update Interval** is set to 1. You might want to increase this value if your profile computation is expensive. See the Fluent Customization Manual for details about creating and using UDFs.

28.12.2. Interrupting Iterations

As mentioned above, you can interrupt the calculation by clicking the **Cancel** button in the **Working** dialog box that appears while the solver is calculating or by typing **Ctrl**+**c** in the console. This will stop the calculation after the current iteration (in steady-state) or after the current time step (in transient). This allows you to stop the calculation process and then start again smoothly with additional iterations or time steps. If you are running a transient simulation and want to interrupt the calculation without waiting for the end of a time step you can type **Ctrl**+**c** a second time.

28.12.3. Resetting Data

After you have performed some iterations, if you decide to start over again from the first iteration (for example, after making some changes to the problem setup), you can reinitialize the solution using the Solution Initialization Task Page (p. 2520), as described in Initializing the Entire Flow Field Using Standard Initialization (p. 1591).

28.13. Performing Pseudo Transient Calculations

For steady-state calculations, when using the pressure-based coupled solver or the density-based implicit solver, you have the option of solving your flow in a pseudo-transient fashion. The pseudo transient under-relaxation method is a form of implicit under-relaxation, described in Pseudo Transient Under-Relaxation in the Theory Guide.

To apply the pseudo transient under-relaxation method, perform the following:

1. Select the **Density-Based** solver or the **Pressure-Based** solver.

   Setup → **General**

2. Go to the **Solution Methods** task page (Figure 28.18: The Solution Methods Task Page (p. 1602)).

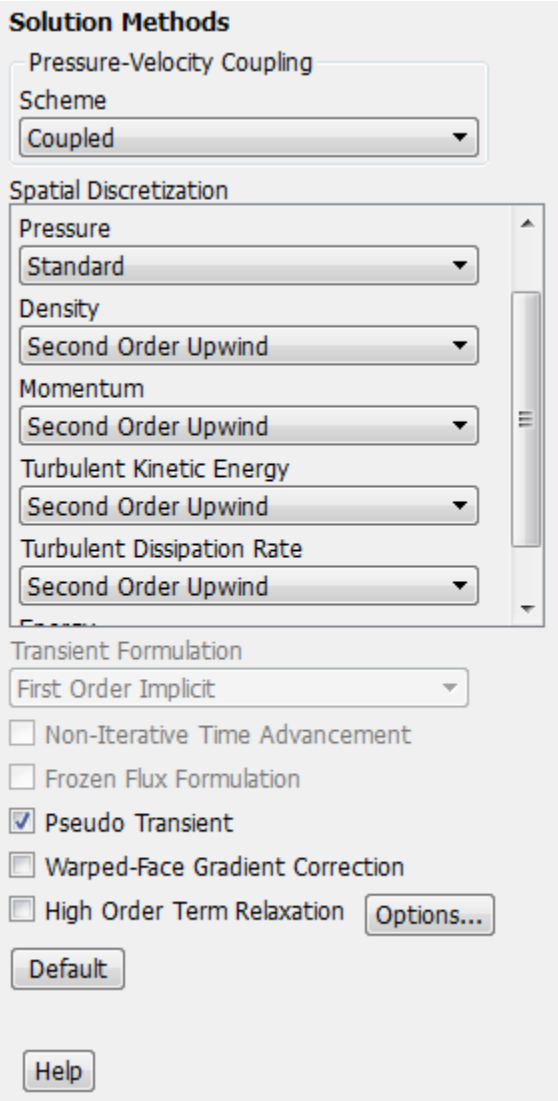
   Solution → **Methods**

   a. If you are using the pressure-based solver, choose the **Coupled** scheme under **Pressure-Velocity Coupling**.

   b. If you are using the density-based solver, choose the **Implicit** scheme under **Formulation**.

   c. Enable the **Pseudo Transient** option.

Figure 28.18: The Solution Methods Task Page



28.13.1. Setting Pseudo Transient Explicit Relaxation Factors

In addition to pseudo transient under-relaxation, you can specify an explicit under-relaxation of the equation to control the update of computed variables at each iteration (see Pseudo Transient Under-Relaxation in the Theory Guide). The default values of under-relaxation parameters for all variables are set to values that work well for most of the cases. It is good practice to start a calculation with the default

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

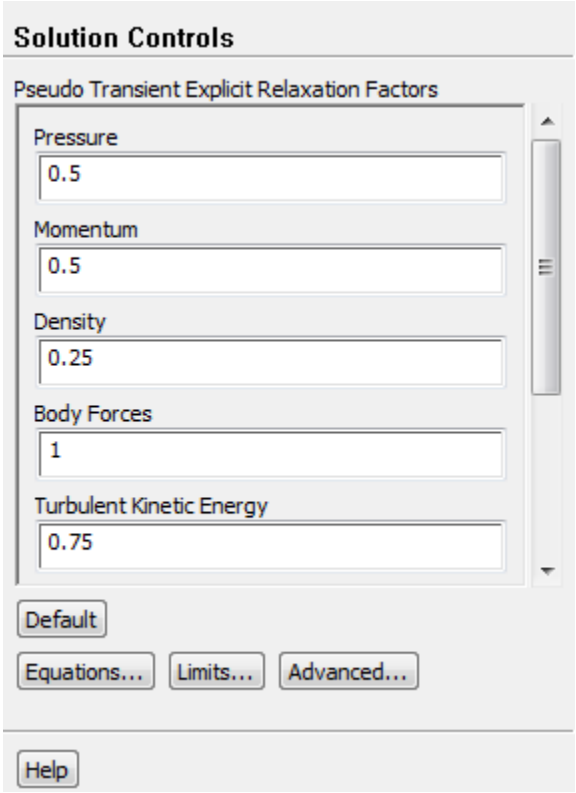
under-relaxation parameters. If your case exhibits divergence or the residuals continue to increase after a few iterations, then you should reduce the under-relaxation factors.

28.13.1.1. User Inputs

You can modify the pseudo transient under-relaxation factors in the Solution Controls Task Page (p. 2508) (Figure 28.19: The Solution Controls Task Page for the Pseudo Transient Runs (p. 1603)).

Solution → Controls

Figure 28.19: The Solution Controls Task Page for the Pseudo Transient Runs



You can set the under-relaxation factor for each equation in the field next to its name under **Pseudo Transient Explicit Relaxation Factors**.

Important

If you are using the pressure-based solver, all equations will have an associated under-relaxation factor (see Under-Relaxation of Equations in the Theory Guide). If you are using the density-based solver, only those equations that are solved sequentially (see Density-Based Solver in the Theory Guide) will have under-relaxation factors.

If you change under-relaxation factors, but you then want to return to ANSYS Fluent's default settings, you can click the **Default** button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.13.2. Setting Solution Controls for the Pseudo Transient Method

To have further control over the parameters for each individual equation, when solving a pseudo transient case, you can go to the **Expert** tab, in the **Advanced Solution Controls** dialog box (Figure 28.20: The Advanced Solution Controls Dialog Box for the Pseudo Transient Method (p. 1605)). Note that all equations, except for flow equations (that is pressure and momentum) will be listed. Generally, you will not need to visit this dialog box to enter equation-specific solution parameters. However, it may help in cases where a particular equation is giving convergence problems. Here, ANSYS Fluent allows two options to improve convergence:

1. Specify a time scale factor for the equation specific time step in lieu of using a uniform global pseudo time step. This scaling factor scales the pseudo time step employed for the flow equations specified in the **Run Calculation** task page (see Solving Pseudo-Transient Flow (p. 1605)).

2. Use the standard steady-state method by turning off pseudo transient for that particular equation. Here, the corresponding under-relaxation factor to be employed with that equation may be specified. The default values of under-relaxation parameters for all variables are set to values that work well for most of the cases.

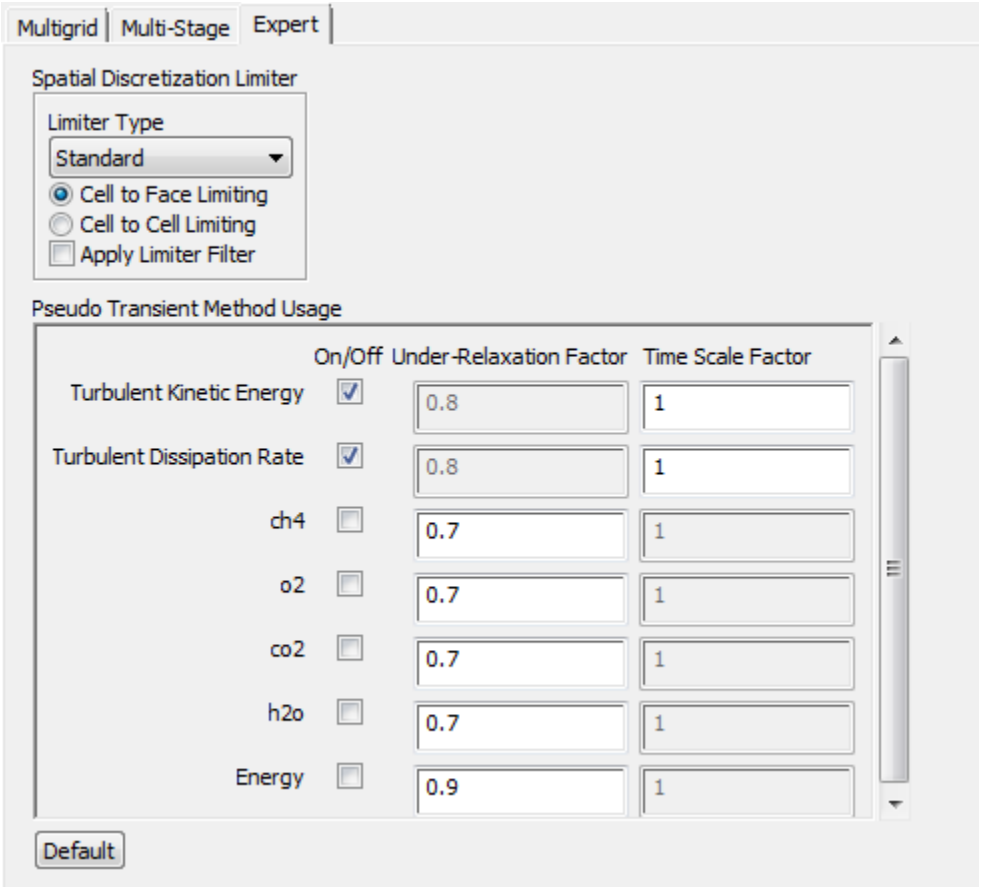
The default setting will have the pseudo transient method turned on for all equations with the corresponding time scale factor set to unity, except when one of the combustion models is used. When the pseudo transient method is enabled In combustion cases the species, enthalpy, and combustion variable equations will only use the pseudo transient method if it is manually enabled in the **Expert** tab. As well, when using the premixed, partially-premixed, or PDF combustion models, the energy equation will only use the pseudo transient method if it is manually enabled in the **Expert** tab.

By default, all user-defined scalars (UDS) have pseudo transient method disabled. This is because the physical parameters of the UDS and the appropriate time scale are not known to the solver before starting the calculation. You can manually enable pseudo transient method for UDS under the **Expert** tab in the Advanced Solution Controls Dialog Box (p. 2513).

Solution → Controls Advanced...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.20: The Advanced Solution Controls Dialog Box for the Pseudo Transient Method



Specify the equation-specific steady-state solution method for a particular equation (if needed) by enabling or disabling the pseudo transient method using the **On/Off** check box next to the equation. The dialog box then allows either specification of a pseudo **Time Scale Factor** or **Under-Relaxation Factor** for that particular equation based on the check box setting.

Note

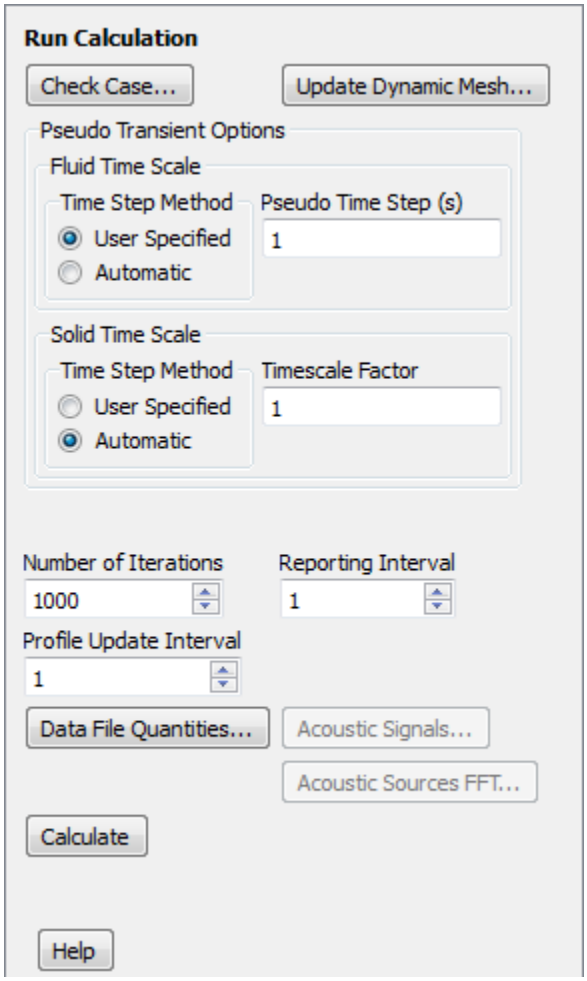
For multiphase flows, the pseudo transient expert options for the volume fraction equation are available only when it is solved in segregated fashion. It is not available when the **Coupled with Volume Fractions** option is enabled in the **Solution Methods** task page (see Selecting the Pressure-Velocity Coupling Method (p. 1507) for information about this setting).

28.13.3. Solving Pseudo-Transient Flow

With the **Pseudo Transient** option enabled in the **Solution Methods** task page, you can now specify the time step for the **Fluid Zone** and/or the **Solid Zone** under **Pseudo Transient Options** in the **Run Calculation** task page (Figure 28.21: The Run Calculation Task Page for the User Specified Pseudo Transient Option (p. 1606)).

Solution → Run Calculation

Figure 28.21: The Run Calculation Task Page for the User Specified Pseudo Transient Option



1. Select the **Time Step Method** for the **Fluid Time Scale**.

   a. If you choose **User Specified**, you will enter the **Pseudo Time Step**, which is used for every equation unless the equation specific time step is used for a particular equation, as mentioned in Setting Solution Controls for the Pseudo Transient Method (p. 1604).

   b. If you choose **Automatic**, which is the default method, (see Figure 28.22: The Run Calculation Task Page for the Automatic Pseudo Transient Option (p. 1607)), the pseudo time step is calculated internally and used for each equation listed, unless the equation has a time step specified as noted in Setting Solution Controls for the Pseudo Transient Method (p. 1604). For more information about the automatic time step calculation, refer to Automatic Pseudo Transient Time Step in the Theory Guide.

      Select the Length Scale Method. Three options are available in the drop-down list:

      i. **Conservative** is the default length scale calculation method, for which you will enter the **Timescale Factor**. The **Timescale Factor** is a scaling factor used to scale the calculated time step. The default value is 1.0. You can increase or decrease it to increase or decrease the size of the time step, respectively.

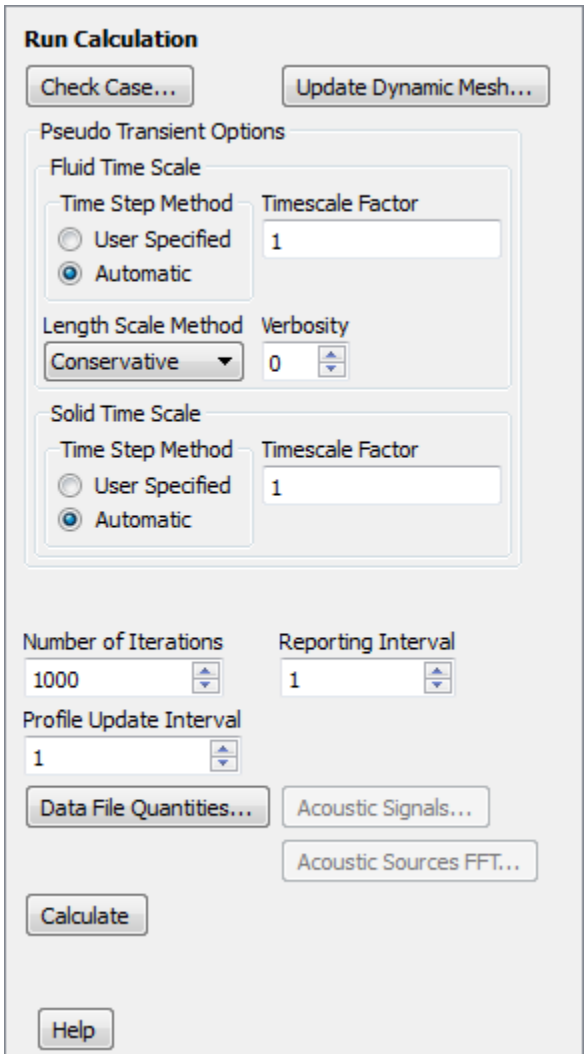
      ii. **Aggressive** predicts a higher time step size than the **Conservative** method. You will also need to specify the **Timescale Factor**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

iii. **User Specified** allows you to control the input for the **Length Scale**. This method is particularly useful in problems that have a specific length scale that is difficult to determine from the overall geometry of the problem. For example, in the case of flow over an airfoil, the appropriate length scale would be the length of the airfoil instead of the length scale calculated based on the geometry of the entire domain.

iv. You can specify the **Verbosity**. This is an integer value of 0 or 1. The default value is 0. If you want to print the pseudo time step size, enter a value of 1 for the **Verbosity**.

Figure 28.22: The Run Calculation Task Page for the Automatic Pseudo Transient Option



2. Select the **Time Step Method** for the **Solid Time Scale**.

Note

Solid Time Scale only appears in the interface when a solid zone is present in the domain or when the **Energy** equation is enabled along with **Porous Zone** or the **Solidification & Melting** model.

---

a. If you choose **User Specified**, you will enter the **Pseudo Time Step**, which is used where the **Solid Time Scale** is needed (that is, solid zones, porous zones, and/or solidification/melting model).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

b. If you choose **Automatic**, which is the default method, the pseudo time step is calculated internally as described in Automatic Pseudo Transient Time Step in the Theory Guide. Specify a **Timescale Factor** to control/adjust the pseudo time step obtained from the automatically calculated **Solid Time Scale**.

3. Continue setting up your solution as you would a steady-state run, as described in Performing Steady-State Calculations (p. 1600).

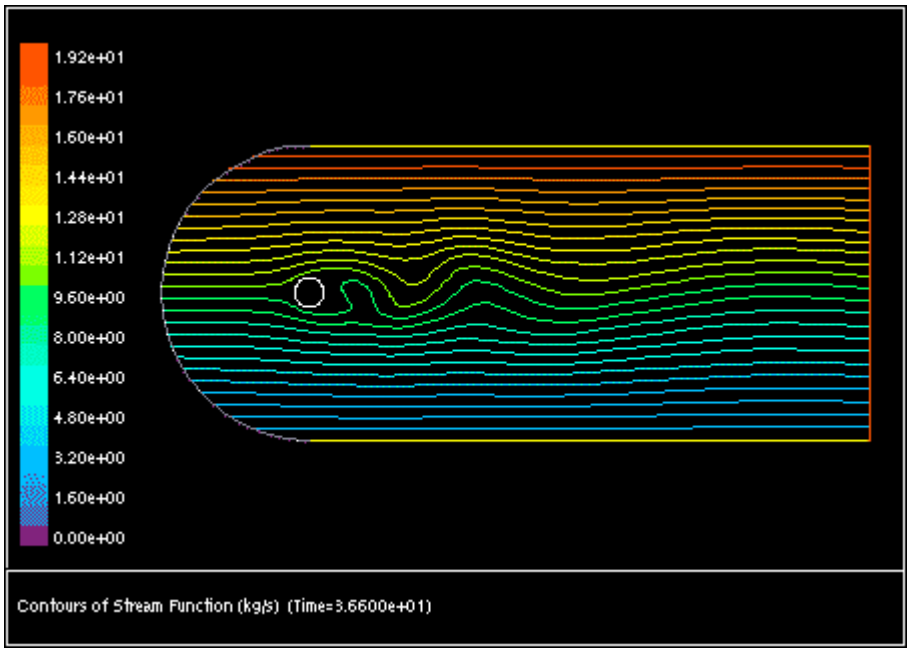
28.14. Performing Time-Dependent Calculations

ANSYS Fluent can solve the conservation equations in a time-dependent manner, to simulate a wide variety of time-dependent phenomena, such as

- vortex shedding and other time-periodic phenomena
- compressible filling and emptying problems
- transient heat conduction
- transient chemical mixing and reactions

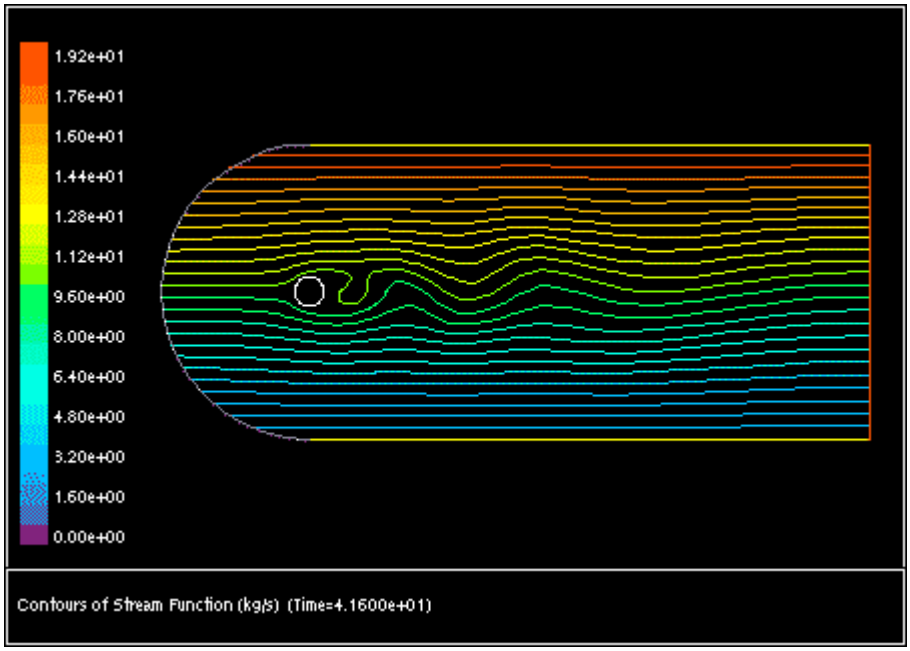
Figure 28.23: Time-Dependent Calculation of Vortex Shedding (t=36.6 sec) (p. 1608) and Figure 28.24: Time-Dependent Calculation of Vortex Shedding (t=41.6 sec) (p. 1609) illustrate the time-dependent vortex shedding flow pattern in the wake of a cylinder.

Figure 28.23: Time-Dependent Calculation of Vortex Shedding (t=36.6 sec)



Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.24: Time-Dependent Calculation of Vortex Shedding (t=41.6 sec)



Enabling time dependence is sometimes useful when attempting to solve steady-state problems that tend toward instability (for example, natural convection problems in which the Rayleigh number is close to the transition region). It is possible in many cases to reach a steady-state solution by integrating the time-dependent equations.

For details about temporal discretization, see Temporal Discretization in the Theory Guide.

For additional information, see the following sections:

28.14.1. User Inputs for Time-Dependent Problems
28.14.2. Adaptive Time Stepping
28.14.3. Variable Time Stepping
28.14.4. Postprocessing for Time-Dependent Problems

28.14.1. User Inputs for Time-Dependent Problems

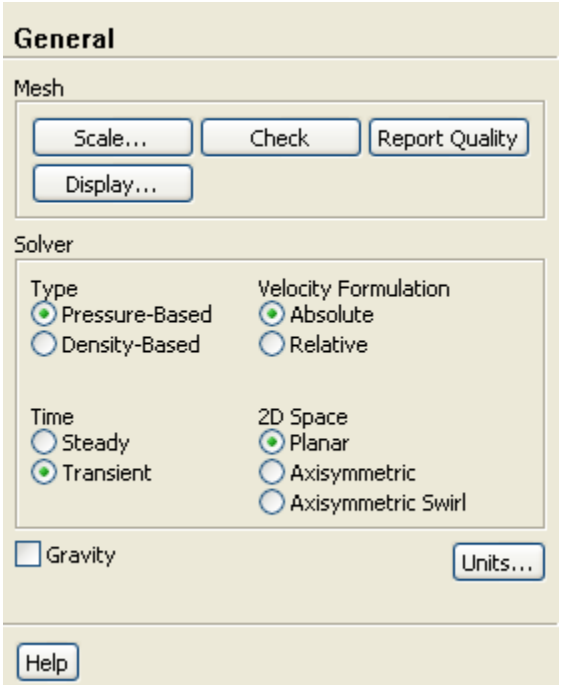
To solve a transient problem, you will follow the procedure outlined below:

1. Enable the **Transient** option in the **General** task page (Figure 28.25: The General Task Page for a Transient Calculation (p. 1610)).

   Setup → **General**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.25: The General Task Page for a Transient Calculation



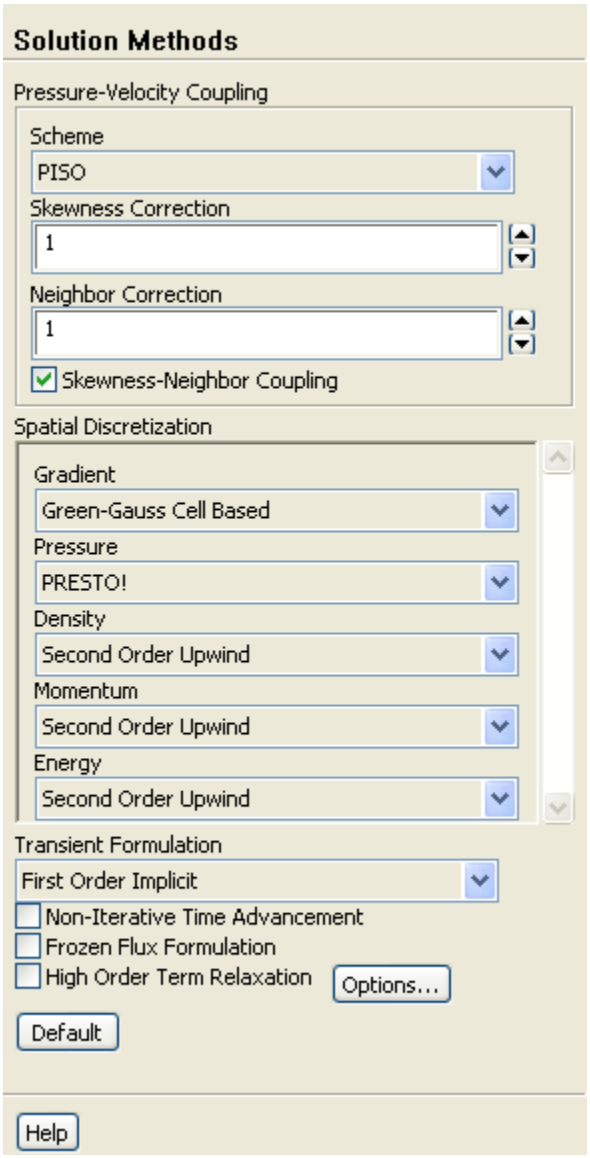
2. Define all relevant models and boundary conditions. Note that any boundary conditions specified using user-defined functions can be made to vary in time. See the Fluent Customization Manual for details.

3. Specify the desired parameters in the **Solution Methods** task page (Figure 28.26: The Solution Methods Task Page for a Transient Calculation (p. 1611)).

   Solution → **Methods**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.26: The Solution Methods Task Page for a Transient Calculation



If you are using the pressure-based solver, select **PISO** from the **Scheme** drop-down list in the **Pressure-Velocity Coupling** group box. To increase the speed of the calculations, you may need to modify the parameters related to the PISO scheme from their default values. See PISO (p. 1562) for more information about the optimal use of the PISO algorithm.

Important

If you are using the LES turbulence model with small time steps, the PISO scheme may be too computationally expensive. It is therefore recommended that you select **SIMPLE** or **SIMPLEC** instead of **PISO**.

Important

It is best to select the **Coupled** pressure-velocity coupling scheme if you are using large time steps to solve your transient flow, or if you have a poor quality mesh.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Next, specify the desired **Transient Formulation**. The **First Order Implicit** formulation is sufficient for most problems. If you need improved accuracy, you can either use **Second Order Implicit** or **Bounded Second Order Implicit**. The **Bounded Second Order Implicit** formulation would provide better stability, since time discretization would always ensure the bounds for variables, if available.

Important

Note that while the **Bounded Second Order Implicit** formulation provides the same accuracy as the **Second Order Implicit** formulation, it actually provides better stability.

Important

The **Bounded Second Order Implicit** formulation is available only for the pressure-based solver, and not for the density-based solver.

The **Explicit** formulation (available only for the density-based solver) is used primarily to capture the transient behavior of moving waves, such as shocks. For details, see Temporal Discretization in the Theory Guide.

When using the pressure-based solver, you have the additional options of selecting **Non-Iterative Time Advancement** and **Frozen Flux Formulation** for your time-dependent flow calculations (see Time-Advancement Algorithm and Steady-State Iterative Algorithm in the Theory Guide, respectively). Note that the latter option is only available for single-phase transient problems that do not use a moving/deforming mesh model.

4. (optional) If you are using the explicit transient formulation with specified Courant number *or* if you are using the adaptive time stepping method (described in a later step and in Adaptive Time Stepping (p. 1618)) it is recommended that you enable the printing of the current time (for the explicit transient formulation) or the current time step size (for the adaptive time stepping method) at each iteration, using Figure 28.34: Report File for 'flow-time', 'delta-time', and 'iters-per-timestep' (p. 1634).

   Solution → **Monitors** → **Statistic** **Edit...**

   Make sure that the desired item is selected from the **Statistics** selection list (**time** for the current time or **delta_time** for the current time step size) and enable the **Print** option. When ANSYS Fluent prints the residuals to the console at each iteration, it will include a column with the current time or the current time step size.

5. (optional) Use the Drag Report Definition Dialog Box (p. 2691), the Lift Report Definition Dialog Box (p. 2724), the Moment Report Definition Dialog Box (p. 2746), or the Surface Report Definition Dialog Box (p. 2807) to monitor (and/or save to a file) time-varying force coefficient values or a report of a field variable or function on a surface as it changes with time. See Monitoring Solution Convergence (p. 1624) for details.

6. Set the initial conditions (at time $t=0$) using the **Solution Initialization** task page.

   Solution → **Initialization**

   You can also read in a steady-state data file to set the initial conditions.

   File → **Read** → **Data...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

7. Use the **Autosave** dialog box to specify the file name and frequency with which case and data files should be saved during the solution process. To open the **Autosave** dialog box, click the **Edit...** button next to **Autosave Every** in the **Calculation Activities** task page.

   Solution → Calculation Activities → Autosave → On

   See Automatic Saving of Case and Data Files (p. 48) for details about automatic file saving.

   The **Calculation Activities** task page also allows you to export solution and particle history data during the transient calculation. See Exporting Data During a Transient Calculation (p. 86) for details.

   If you want to create a graphical animation of the solution over time, you can use Figure 28.43: The Animation Definition Dialog Box (p. 1648) to set up the graphical displays that you want to use in the animation. See Animating the Solution (p. 1647) for details.

   You may also want to request automatic execution of other commands using the Execute Commands Dialog Box (p. 2535). See Executing Commands During the Calculation (p. 1638) for details.

8. (optional) You can improve the convergence of the transient calculations by enabling the **Extrapolate Variables** option in the Run Calculation Task Page (p. 2537). This option instructs ANSYS Fluent to predict the solution variable values for the next time step using a Taylor series expansion, and then inputs that predicted value as an initial guess for the inner iterations of the current time step. As a result, the absolute residual levels are lowered.

   Note that the **Extrapolate Variables** option is not available if you are employing either the NITA scheme with the pressure-based solver or the explicit formulation with the density-based solver.

   Important

   If you use the **Extrapolate Variables** option when modeling an incompressible flow with the density-based solver, it is recommended that you disable the extrapolation of pressure values. After you have enabled the **Extrapolate Variables** option, type the following text command in the console:

```
> solve/set/extrapolate-eqn-vars/pressure

Extrapolate Pressure? [yes] no
```

9. (optional) If you want ANSYS Fluent to gather data for time statistics (that is, time-averaged, root-mean-square, and root-mean-square-error values for solution variables) during the calculation, follow these steps:

   a. Create a custom field function for the each of the variables for which you want to postprocess unsteady statistics (for example, P*|V|), using the **Custom Field Function Calculator**. For detailed instructions, see Creating a Custom Field Function (p. 2004). Note that you do not need to take the extra step of creating custom field functions for the flow shear stresses, flow heat fluxes, wall statistics, or discrete phase variables as there are options for selecting these variables directly in a later step.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Parameters & Customization → Custom Field Functions → New...

Important

The maximum number of custom field functions that can be calculated and postprocessed for unsteady statistics is 50.

b. Enable the **Data Sampling for Time Statistics** option in the Run Calculation Task Page (p. 2537).

Solution → Run Calculation → Data Sampling for Time Statistics

Enabling this option will allow you to display and report the mean, the root-mean-square (RMS), and the root-mean-square-error (RMSE) values, as described in Postprocessing for Time-Dependent Problems (p. 1622).

To specify the sampling interval, enter a value for **Sampling Interval**.

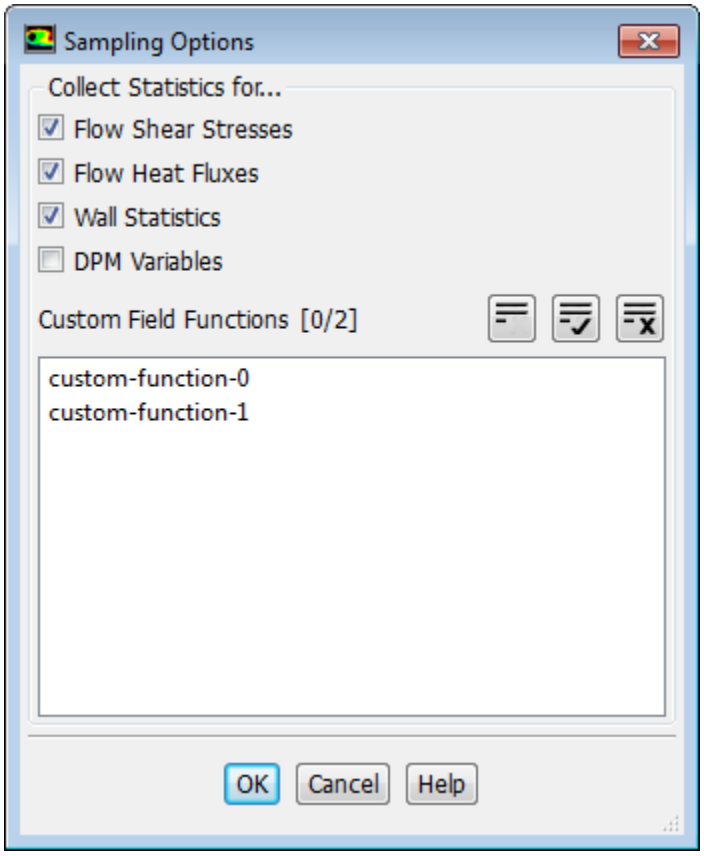
The **Time Sampled** displays the time period over which data has been sampled for the postprocessing of the mean, RMS, and RMSE values. For most quantities, as long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. However, special consideration is required in the case of discrete phase quantities. As noted in Reporting of Unsteady DPM Statistics (p. 1353), sampling of DPM quantities occurs only when parcels pass through a cell, not necessarily at each specified sampling interval. Therefore, the number of samples of the DPM quantities taken during the sampled time period is stored in the separate postprocessing variable, **Accum DPM Parcels in Cell**. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

To select the variables (which may be represented as custom field functions) for which you want to collect statistics, click the **Sampling Options...** button and make selections from the **Sampling Options** dialog box that opens (Figure 28.27: The Sampling Options Dialog Box (p. 1615)). Note that no custom field functions are selected by default.

Solution → Run Calculation → Sampling Options...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.27: The Sampling Options Dialog Box



Important

Note that gathering data for time statistics is not meaningful inside a moving cell zone (for example, a sliding zone in a sliding mesh problem, a moving zone in a dynamic mesh problem).

c. Initialize the flow statistics.

Solution → **Initialization** **Reset Statistics**

Note that you can also reset the flow statistics after you have gathered some data for time statistics. If you perform, say, 10 time steps with the **Data Sampling for Time Statistics** option enabled, check the results, and then continue the calculation for 10 more time steps, the time statistics will include the data gathered in the first 10 time steps unless you reinitialize the flow statistics.

10. Specify time-dependent solution parameters and start the calculation as described below for the implicit and explicit transient formulations:

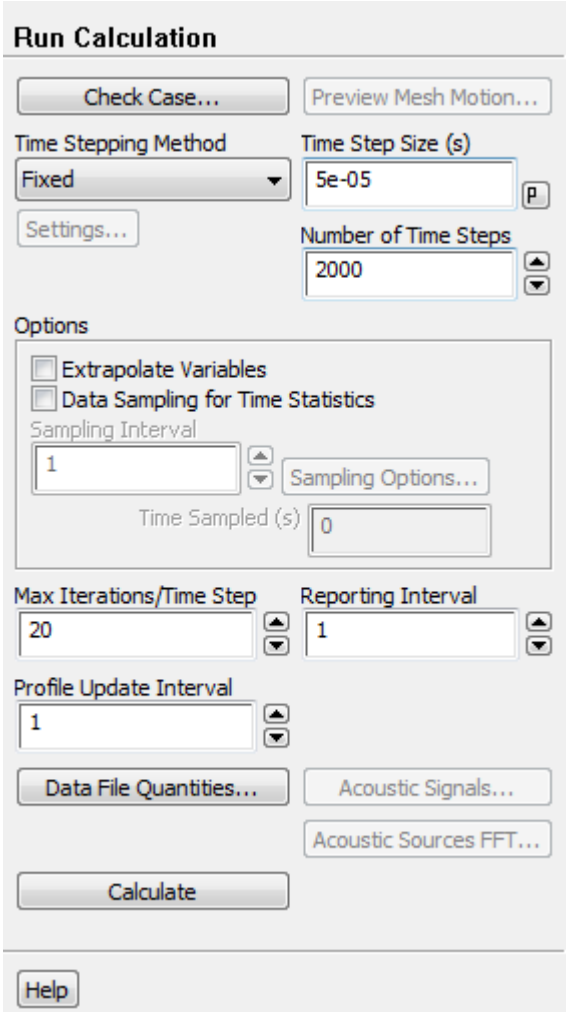
- If you have chosen the **First Order Implicit**, **Second Order Implicit**, or **Bounded Second Order Implicit** formulation, the procedure is as follows:

  a. Set the time-dependent solution parameters in the Run Calculation Task Page (p. 2537) (see Figure 28.28: The Run Calculation Task Page for Implicit Transient Calculations (p. 1616)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solution → Run Calculation

Figure 28.28: The Run Calculation Task Page for Implicit Transient Calculations



Solution parameters for the implicit transient formulations are as follows:

– **Max Iterations/Time Step**: When ANSYS Fluent solves the time-dependent equations using the implicit formulation, multiple iterations may be necessary at each time step. This parameter sets a maximum for the number of iterations per time step. If the convergence criteria are met before this number of iterations is performed, the solution will advance to the next time step.

– **Time Step Size**: The time step size is the magnitude of Δt. Since the ANSYS Fluent formulation is fully implicit, there is no stability criterion that must be met in determining Δt. However, to model transient phenomena properly, it is necessary to set Δt at least one order of magnitude smaller than the smallest time constant in the system being modeled. A good way to judge the choice of Δt is to observe the number of iterations ANSYS Fluent needs to converge at each time step. The ideal number of iterations per time step is 5–10. If ANSYS Fluent needs substantially more, the time step is too large. If ANSYS Fluent needs only a few iterations per time step, Δt should be increased. Frequently a time-dependent problem has a very fast "startup" transient that decays rapidly. Therefore, it is often wise to choose a conservatively small Δt for the first 5–10 time steps. Δt may then be gradually increased as the calculation proceeds.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

For time-periodic calculations, you should choose the time step based on the time scale of the periodicity. For a rotor/stator model, for example, you might want 20 time steps between each blade passing. For vortex shedding, you might want 20 steps per period.

To verify that your choice for Δt was proper after the calculation is complete, you can plot contours of the Courant number within the domain. To do so, select **Velocity...** and **Cell Convective Courant Number** from the **Contours of** drop-down lists in the **Contours** dialog box. For a stable, efficient calculation, the Courant number should not exceed a value of 20–40 in most sensitive transient regions of the domain.

– **Time Stepping Method**: By default, the size of the time step is fixed (as indicated by the selection of **Fixed**).

To have ANSYS Fluent modify the size of the time step as the calculation proceeds, select **Adaptive** and click the **Settings...** button to specify the parameters in the **Adaptive Time Step Settings** dialog box. See Adaptive Time Stepping (p. 1618) for details.

For transient volume of fluid (VOF) or Eulerian Multiphase calculations you can select the **Variable** time stepping method. The parameters set through the **Parameters...** button are in many ways the same as for the adaptive time stepping method, with the exception of specifying a global Courant number (see Variable Time Stepping (p. 1621)).

Note that with the **Adaptive** or **Variable** time stepping method, the value you specify for the **Time Step Size** will be the initial size of the time step. As the calculation proceeds, the **Time Step Size** shown in the **Run Calculation** task page will be the size of the *current* time step.

b. Specify the desired **Number of Time Steps** in the **Run Calculation** task page and click **Calculate**.

As it calculates a solution, ANSYS Fluent will print the current time at the end of each time step.

- If you choose the **Explicit** transient formulation, you have two input options available for specifying the transient solution advancement. You can specify the transient advancement either directly by specifying a time step size ($\triangle t$) or indirectly via entering a Courant number value (CFL).

a. Under the **Solution Control** panel , if the default option `Specified Time Step` is selected, you will be required to specify the time step size and the `Number of Time Steps` in the **Run Calculation** task page.

Alternatively, if you do not select the `Specified Time Step` option, you will be required to specify the `Courant Number` under the **Solution Control** task page and the `Number of Iterations` in the **Run Calculation** task page. In this option the (CFL) value is used to calculate the time step size ($\triangle t$) using Equation 28.1 (p. 1617):

$$\triangle t = \frac{2 * CFL * V}{\sum_f \lambda_f^{\max} * A_f} \tag{28.1}$$

where, V is the volume of the cell, A_f is the face area, and $\lambda_f^{\max}$ is the maximum local eigenvalue defined in Equation 21.76 in the *Fluent Theory Guide*.

b. Under the **Run Calculation** task page:

– If the Specified Time Step option is selected in the **Solution Control** panel, you need to specify the Time Step Size and the Number of Time Steps.

→ **Time Step Size**: For this option, you have to set the magnitude of $\triangle t$.

> **Note**
>
> The stability of an explicit formulation is limited by the Courant-Fredrichs-Lewy condition. Fluent checks the specified time step against the stability limit. The stability limit is the maximum allowable time step size calculated based on CFL=1 in Equation 28.1 (p. 1617). The stability limit is also the minimum of all local time steps in the domain. If the specified time step size is larger than the maximum allowable time step, Fluent displays a warning during the calculation.

→ **Number of Time Steps**: Specify the desired number of time steps and click **Calculate**

– If the Specified Time Step option is not selected in the **Solution Control** panel then you need to specify the desired Number of Iterations and click **Calculate**.

For explicit transient formulations, every iteration is a time step. The output for results in the Fluent console will include a column indicating the current time (if you have enabled the printing of the current time under adaptive time stepping method).

- You can access the information saved in a data file, which includes a standard set of quantities that were computed during the calculation, by clicking the **Data File Quantities...** button. More information about this feature is available in Setting Data File Quantities (p. 107).

11. Save the final data file (and case file, if you have modified it) so that you can continue the transient calculation later, if desired.

File → **Write** → **Data...**

28.14.1.1. Additional Inputs

The procedures for setting the reporting interval, updating user-defined function profiles, interrupting iterations, and resetting data are the same as those for steady-state calculations. See Performing Steady-State Calculations (p. 1600) for details.

> **Important**
>
> If you are using a user-defined function in your time-dependent calculation, note that, in addition to being updated after every n iterations (where n is the value of the **Profile Update Interval**), the function will also be updated at the first iteration of each time step.

28.14.2. Adaptive Time Stepping

As mentioned in User Inputs for Time-Dependent Problems (p. 1609), it is possible to have the size of the time step change as the calculation proceeds, rather than specifying a fixed size for the entire calculation. This section provides a brief description of the algorithm that ANSYS Fluent uses to compute the time

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

step size, as well as an explanation of each of the parameters that you can set to control the adaptive time stepping.

Important

Adaptive time stepping is available only with the pressure-based and density-based implicit formulations; it cannot be used with the density-based explicit formulation. In addition, it cannot be used with the discrete phase model, second-order time integration, or Euler-Euler multiphase models (Approaches to Multiphase Modeling in the Theory Guide).

28.14.2.1. The Adaptive Time Stepping Algorithm

The automatic determination of the time step size is based on the estimation of the truncation error associated with the time integration scheme. If the truncation error is smaller than a specified tolerance, the size of the time step is increased; if the truncation error is greater, the time step size is decreased.

An estimation of the truncation error can be obtained by using a predictor-corrector type of algorithm [39] (p. 2889) in association with the time integration scheme. At each time step, a predicted solution can be obtained using a computationally inexpensive explicit method (forward Euler for the first-order unsteady formulation, Adams-Bashford for the second-order unsteady formulation). This predicted solution is used as an initial condition for the time step, and the correction is computed using the nonlinear iterations associated with the implicit (pressure-based or density-based) formulation. The norm of the difference between the predicted and corrected solutions is used as a measure of the truncation error. By comparing the truncation error with the desired level of accuracy (that is, the truncation error tolerance), ANSYS Fluent is able to adjust the time step size by increasing it or decreasing it.

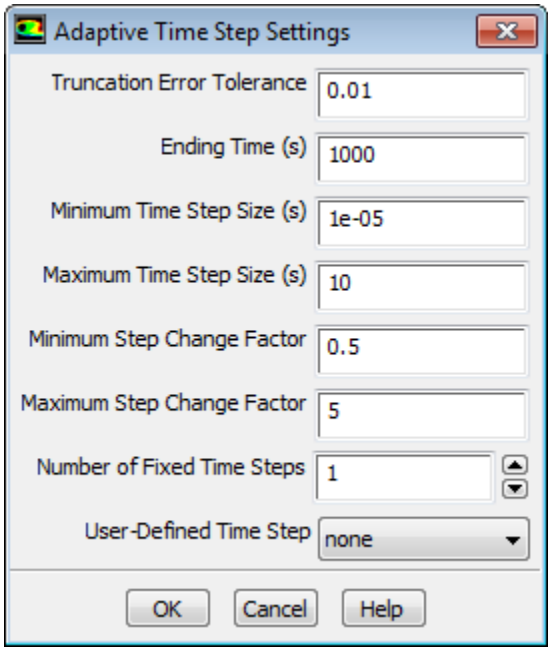
In cases where the truncation error remains above the specified tolerance, ANSYS Fluent will try to meet the tolerance within 5 attempts. If this tolerance is met, then the iteration moves on to the next time step. An explicit scheme is used to predict the solution at each time step, then the explicit prediction is corrected with an implicit scheme. The truncation error, which is a function of the difference between the predicted and corrected solutions at a specific time is used to calculate the next time step. However, if the calculated truncation error is greater than the tolerance limit, we have the option of reverting from the currently performed iteration, which is moving from the n^{th} step to $n+1^{\text{th}}$ step, and performing the iteration with a smaller time step. Note that this option is not available for moving deforming meshes, sliding meshes, and the discrete phase model. Since the truncation error is proportional to the time step, decreasing the time step reduces the truncation error. This can be done until the truncation error goes below the tolerance limit.

28.14.2.2. Specifying Parameters for Adaptive Time Stepping

The parameters that control the adaptive time stepping appear in the **Adaptive Time Step Settings** dialog box, as described in User Inputs for Time-Dependent Problems (p. 1609).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.29: The Adaptive Time Step Settings Dialog Box for Implicit Unsteady Calculations and Adaptive Time Stepping



These parameters are as follows:

Truncation Error Tolerance

specifies the threshold value to which the computed truncation error is compared. Increasing this value will lead to an increase in the size of the time step and a reduction in the accuracy of the solution. Decreasing it will lead to a reduction in the size of the time step and an increase in the solution accuracy, although the calculation will require more computational time. For most cases, the default value of 0.01 is acceptable.

Ending Time

specifies an ending time for the calculation. Since the ending time cannot be determined by multiplying the number of time steps by a fixed time step size, you need to specify it explicitly.

Minimum/Maximum Time Step Size

specify the upper and lower limits for the size of the time step. If the time step becomes very small, the computational expense may be too high; if the time step becomes very large, the solution accuracy may not be acceptable to you. You can set the limits that are appropriate for your simulation.

Minimum/Maximum Step Change Factor

limit the degree to which the time step size can change at each time step. Limiting the change results in a smoother calculation of the time step size, especially when high-frequency noise is present in the solution. If the time step change factor, f, is computed as the ratio between the specified truncation error tolerance and the computed truncation error, the size of time step Δt_n is computed as follows:

- If $1<f<f_{max}$, Δt_n is increased to meet the desired tolerance.
- If $1<f_{max}<f$, Δt_n is increased, but its maximum possible value is $f_{max}\Delta t_{n-1}$.
- If $f_{min}<f<1$, Δt_n is unchanged.
- If $f<f_{min}<1$, Δt_n is decreased.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Number of Fixed Time Steps

specifies the number of fixed-size time steps that should be performed before the size of the time step starts to change. The size of the fixed time step is the value specified for **Time Step Size** in the **Run Calculation** task page.

It is a good idea to perform a few fixed-size time steps before switching to the adaptive time stepping. Sometimes spurious discretization errors can be associated with an impulsive start in time. These errors are dissipated during the first few time steps, but they can adversely affect the adaptive time stepping and result in extremely small time steps at the beginning of the calculation.

Important

When the solution tends to exhibit incomplete convergence, rather than increasing the time step size or keeping the same time step size in the next step, ANSYS Fluent reduces the time step size by at least half for the next time step (making sure that the time step size does not go below the specified minimum time step size.

28.14.2.3. Specifying a User-Defined Time Stepping Method

If you want to use your own adaptive time stepping method, instead of the method described above, you can create a user-defined function for your method and select it in the **User-Defined Time Step** drop-down list. The other inputs in the **Adaptive Time Step Settings** dialog box will not be used when you select a user-defined function.

See the Fluent Customization Manual for details about creating and using user-defined functions.

28.14.3. Variable Time Stepping

For VOF and Eulerian multiphase calculations, ANSYS Fluent allows you to use variable time stepping in order to automatically change the time step when an interface is moving through dense cells or if the interface velocity is high.

Variable time stepping is available for both the explicit and the implicit volume fraction formulations when using the VOF model. For the Eulerian multiphase model it is only available when using the Multi-Fluid VOF option or when using the explicit volume fraction formulation.

28.14.3.1. The Variable Time Stepping Algorithm

The global time step Δt_{global} is changed in the following manner:

$$\Delta t_{global} = \frac{CFL_{global}}{max\left(\sum \frac{outgoing\ \ fluxes}{volume}\right)} \tag{28.2}$$

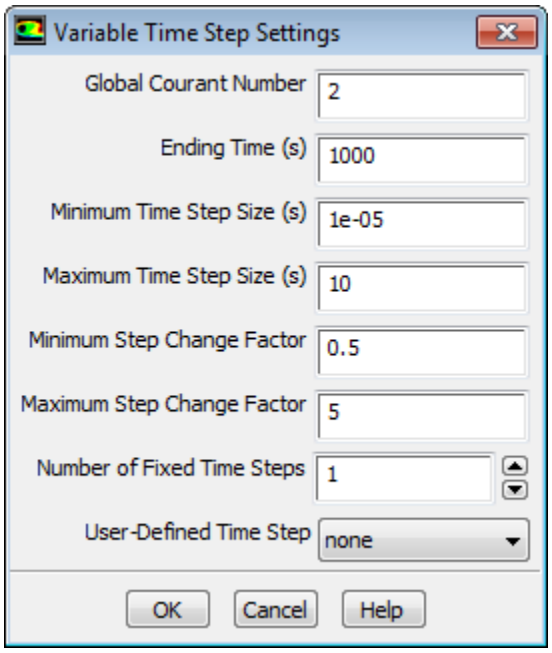
where the ratio $\sum \frac{outgoing\ \ fluxes}{volume}$ is calculated for each cell. ANSYS Fluent takes the maximum of this ratio to calculate the global time step.

28.14.3.2. Specifying Parameters for Variable Time Stepping

For transient VOF calculations, when **Variable** is selected from the **Time Stepping Method** drop-down list, in the **Run Calculation** task page and the **Settings...** button is clicked, the **Variable Time Step Settings** dialog box will open (Figure 28.30: The Variable Time Step Settings Dialog Box for Implicit Unsteady Calculations and Variable Time Stepping (p. 1622)). With the exception of the **Global Courant**

Number field, all parameters are the same as for adaptive time stepping (see Adaptive Time Stepping (p. 1618)). The default value for the **Global Courant Number** is 2.

Figure 28.30: The Variable Time Step Settings Dialog Box for Implicit Unsteady Calculations and Variable Time Stepping



The variable time step is based on the maximum Courant number near the VOF interface. To calculate that Courant number, ANSYS Fluent uses a flux-based definition where, in the region near the fluid interface, ANSYS Fluent divides the volume of each cell by the sum of the outgoing fluxes. The resulting time represents the time it would take for the fluid to empty out of the cell. The smallest such time is used as the characteristic time of transit for a fluid element across a control volume.

Note

When choosing the values for Minimum and Maximum Step Change Factors, it is generally not recommended to allow large variation in time step size due to stability considerations. This is especially true when time step size is ramping up.

Variable time stepping is not ideally suited to second order time formulation because the second order formulation does not take into account the time step size variation. However, by keeping the minimum time step change factor in the range 0.5–0.8 and the maximum time step change factor in the range 1.2–1.5 it can be used without severely affecting the second order time accuracy.

28.14.4. Postprocessing for Time-Dependent Problems

The postprocessing of time-dependent data is similar to that for steady-state data, with all graphical and alphanumeric commands available. You can read a data file that was saved at any point in the calculation (by you or with the autosave option) to restore the data at any of the time levels that were saved.

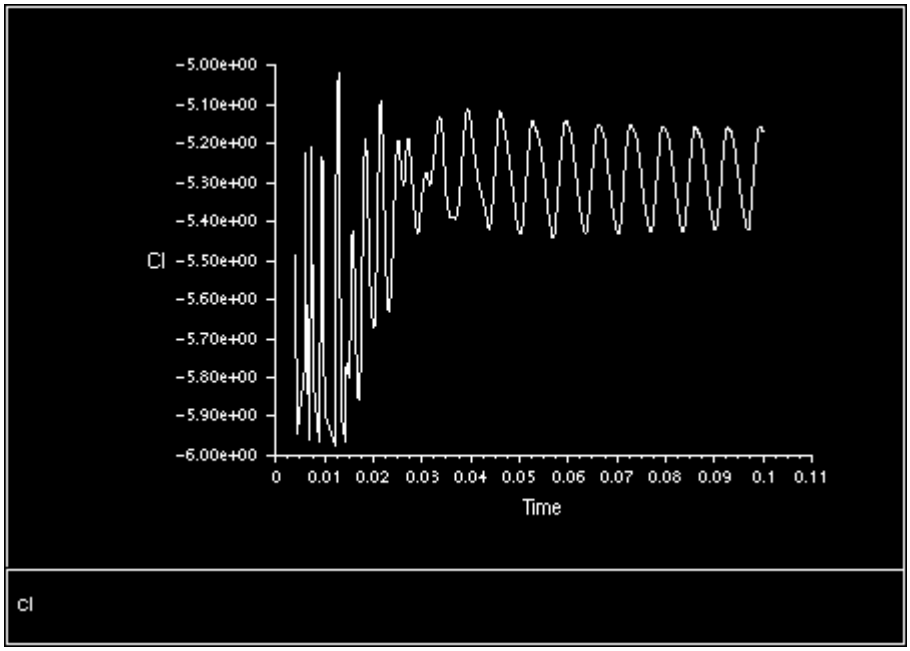
File → Read → Data...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

ANSYS Fluent will label any subsequent graphical or alphanumeric output with the time value of the current data set.

If you save data from the force or surface report definitions to files (see step 5 in User Inputs for Time-Dependent Problems (p. 1609)), you can read these files back in and plot them to see a time history of the monitored quantity. Figure 28.31: Lift Coefficient Plot for a Time-Periodic Solution (p. 1623) shows a sample plot generated in this way.

Figure 28.31: Lift Coefficient Plot for a Time-Periodic Solution



If you enable the **Data Sampling for Time Statistics** option in the Run Calculation Task Page (p. 2537) (see Performing Time-Dependent Calculations (p. 1608) for details), ANSYS Fluent will compute the time average (mean) of the instantaneous values, the root-mean-square, and the root-mean-square-errors of those quantities and custom field functions that are enabled/selected in the **Sampling Options** dialog box.

The **Time Sampled** displays the time over which data has been sampled for the postprocessing of the mean, RMS, and RMSE values. For most quantities, as long as the time step size has been constant, dividing this by the time step size yields the number of data sets that have been collected. However, special consideration is required In the case of discrete phase quantities. As noted in Reporting of Unsteady DPM Statistics (p. 1353), sampling of DPM quantities occurs only when parcels pass through a cell, not necessarily at each specified sampling interval. Therefore, the number of samples of the DPM quantities taken during the sampled time period is stored in the separate postprocessing variable, **Accum DPM Parcels in Cell**. If the time step size is varied, every contribution of data sets sampled is automatically weighted by the current time step size.

The mean, root-mean-square(RMS), and root-mean-square-error (RMSE) values for solution variables will be available in the **Unsteady Statistics...** category (or the **Unsteady DPM Statistics...** category for discrete phase quantities) of the variable selection drop-down list that appears in postprocessing dialog boxes. For example, in the **Contours** dialog box, you could select **Unsteady Statistics...** and **RMSE-uns-custom-functon-0** for the **Contours of** drop-down lists in order to display the root-mean-square-errors of a custom field function named **uns-custom-functon-0**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.15. Monitoring Solution Convergence

During the solution process you can monitor the convergence dynamically by checking residuals, statistics, force values, surface integrals, and volume integrals. You can print reports of or display plots of lift, drag, and moment coefficients, surface integrations, and residuals for the solution variables. For unsteady flows, you can also monitor elapsed time. Creating report definitions for monitoring is described in Creating Report Definitions (p. 1886).

For additional information, see the following sections:

28.15.1. Monitoring Residuals
28.15.2. Monitoring Statistics
28.15.3. Monitoring Solution Quantities

28.15.1. Monitoring Residuals

At the end of each solver iteration, the residual sum for each of the conserved variables is computed and stored, thereby recording the convergence history. This history is also saved in the data file. The residual sum is defined below.

On a computer with infinite precision, these residuals will go to zero as the solution converges. On an actual computer, the residuals decay to some small value ("round-off") and then stop changing ("level out"). For single-precision computations (the default for workstations and most computers), residuals can drop as many as six orders of magnitude before hitting round-off. Double-precision residuals can drop up to twelve orders of magnitude. Guidelines for judging convergence can be found in Judging Convergence (p. 1668).

28.15.1.1. Definition of Residuals for the Pressure-Based Solver

After discretization, the conservation equation for a general variable ϕ at a cell P can be written as

$$a_P \phi_P = \sum_{nb} a_{nb} \phi_{nb} + b \tag{28.3}$$

Here a_P is the center coefficient, a_{nb} are the influence coefficients for the neighboring cells, and b is the contribution of the constant part of the source term S_c in $S = S_c + S_P \phi$ and of the boundary conditions. In Equation 28.3 (p. 1624),

$$a_P = \sum_{nb} a_{nb} - S_P \tag{28.4}$$

The residual R^{ϕ} computed by ANSYS Fluent's pressure-based solver is the imbalance in Equation 28.3 (p. 1624) summed over all the computational cells P. This is referred to as the "unscaled" residual. It may be written as

$$R^{\phi} = \sum_{cells\ P} \left| \sum_{nb} a_{nb} \phi_{nb} + b - a_P \phi_P \right| \tag{28.5}$$

In general, it is difficult to judge convergence by examining the residuals defined by Equation 28.5 (p. 1624) since no scaling is employed. This is especially true in enclosed flows such as natural convection in a room where there is no inlet flow rate of ϕ with which to compare the residual.

ANSYS Fluent scales the residual using two kinds of scaling factors, representative of the flow rate of ϕ through the domain. The factors are termed *global scaling* and *local scaling*. The type of scaling can be selected from the **Residual Monitors** dialog box. The "globally scaled" residual is defined as

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

$$R^{\phi}=\frac{\sum_{\text{cells } P}\left|\sum_{nb}a_{nb}\phi_{nb}+b-a_P\phi_P\right|}{\sum_{\text{cells } P}\left|a_P\phi_P\right|} \tag{28.6}$$

For the momentum equations the denominator term $a_P\phi_P$ is replaced by $a_P v_P$, where v_P is the magnitude of the velocity at cell P.

The "locally scaled" residual is defined as

$$R_{\phi}=\frac{\sqrt{\sum_{\text{cells}}^{n}\left(\frac{1}{n}\right)\left(\frac{\sum_{nb}a_{nb}\phi_{nb}+b-a_p\phi_p}{a_p}\right)^2}}{\left(\phi_{max}-\phi_{min}\right)_{domain}} \tag{28.7}$$

As in global scaling, for the momentum, ϕ is replaced by v of the cell.

The scaled residual is a more appropriate indicator of convergence for most problems. The selection of scaling and convergence criteria for different types of scaling are discussed in Judging Convergence (p. 1668). The default residuals displayed by ANSYS Fluent are global scaling.

For the continuity equation, the unscaled residual for the pressure-based solver is defined as

$$R^{c}=\sum_{\text{cells } P}\left|\text{rate of mass creation in cell P}\right| \tag{28.8}$$

The local scaling is the same for all equations. However, the global scaling treats continuity in a different way and it is defined as

$$\frac{R^{c}_{\text{iteration } N}}{R^{c}_{\text{iteration } 5}} \tag{28.9}$$

The denominator is the largest absolute value of the continuity residual in the first five iterations.

The scaled residuals described above are useful indicators of solution convergence. Guidelines for their use are given in Judging Convergence (p. 1668). It is sometimes useful to determine how much a residual has decreased during calculations as an additional measure of convergence. For this purpose, ANSYS Fluent allows you to normalize the residual (either scaled or unscaled) by dividing by the maximum residual value after M iterations, where M is set by you in the Residual Monitors Dialog Box (p. 2789) in the **Iterations** field under **Residual Values**.

$$\overline{R}^{\phi}=\frac{R^{\phi}_{\text{iteration } N}}{R^{\phi}_{\text{iteration } M}} \tag{28.10}$$

Normalization in this manner ensures that the initial residuals for all equations are of $O(1)$ and is sometimes useful in judging overall convergence.

By default, $M=5$. You can also specify the normalization factor (the denominator in Equation 28.10 (p. 1625)) manually in the Residual Monitors Dialog Box (p. 2789).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.15.1.2. Definition of Residuals for the Density-Based Solver

A residual for the density-based solver is simply the time rate of change of the conserved variable (W). The RMS residual is the square root of the average of the squares of the residuals in each cell of the domain:

$$R(W)=\sqrt{\sum\left(\frac{\partial W}{\partial t}\right)^2} \tag{28.11}$$

Equation 28.11 (p. 1626) is the unscaled residual sum reported for all the coupled equations solved by ANSYS Fluent's density-based solver.

Important

The residuals for the equations that are solved sequentially by the density-based solver (turbulence and other scalars, as discussed in Density-Based Solver in the Theory Guide) are the same as those described above for the pressure-based solver.

In general, it is difficult to judge convergence by examining the residuals defined by Equation 28.11 (p. 1626) since no scaling is employed. This is especially true in enclosed flows such as natural convection in a room where there is no inlet flow rate of ϕ with which to compare the residual. As with the pressure-based solver, ANSYS Fluent uses two types of scaling for the density-based solver. The globally scaled residual is defined as

$$\frac{R(\mathrm{W})_{\text{iteration } N}}{R(\mathrm{W})_{\text{iteration } 5}} \tag{28.12}$$

The denominator is the largest absolute value of the residual in the first five iterations.

The locally scaled residual is calculated from the local flux imbalance in the cell. It is calculated using Equation 28.13 (p. 1626):

$$R_\phi=\frac{\sqrt{\sum_{n}^{cells}\left(\frac{1}{n}\right)\left(\frac{\partial w}{\partial t}V\right)^2}}{(w_{max}-w_{min})_{domain}} \tag{28.13}$$

w is the conservative variable and V is the cell volume. The unscaled residual is always calculated from Equation 28.11 (p. 1626).

The scaled residuals described above are useful indicators of solution convergence. Guidelines for their use are given in Judging Convergence (p. 1668). It is sometimes useful to determine how much a residual has decreased during calculations as an additional measure of convergence. For this purpose, ANSYS Fluent allows you to normalize the residual (either scaled or unscaled) by dividing by the maximum residual value after M iterations, where M is set by you in the Residual Monitors Dialog Box (p. 2789) in the **Iterations** field under **Residual Values**.

Normalization of the residual sum is accomplished by dividing by the maximum residual value after M iterations, where M is set by you in the Residual Monitors Dialog Box (p. 2789) in the **Iterations** field under **Residual Values**:

$$\overline{R}(\mathrm{W})=\frac{R(\mathrm{W})_{\text{iteration } N}}{R(\mathrm{W})_{\text{iteration } M}} \tag{28.14}$$

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Normalization in this manner ensures that the initial residuals for all equations are of $O(1)$ and is sometimes useful in judging overall convergence.

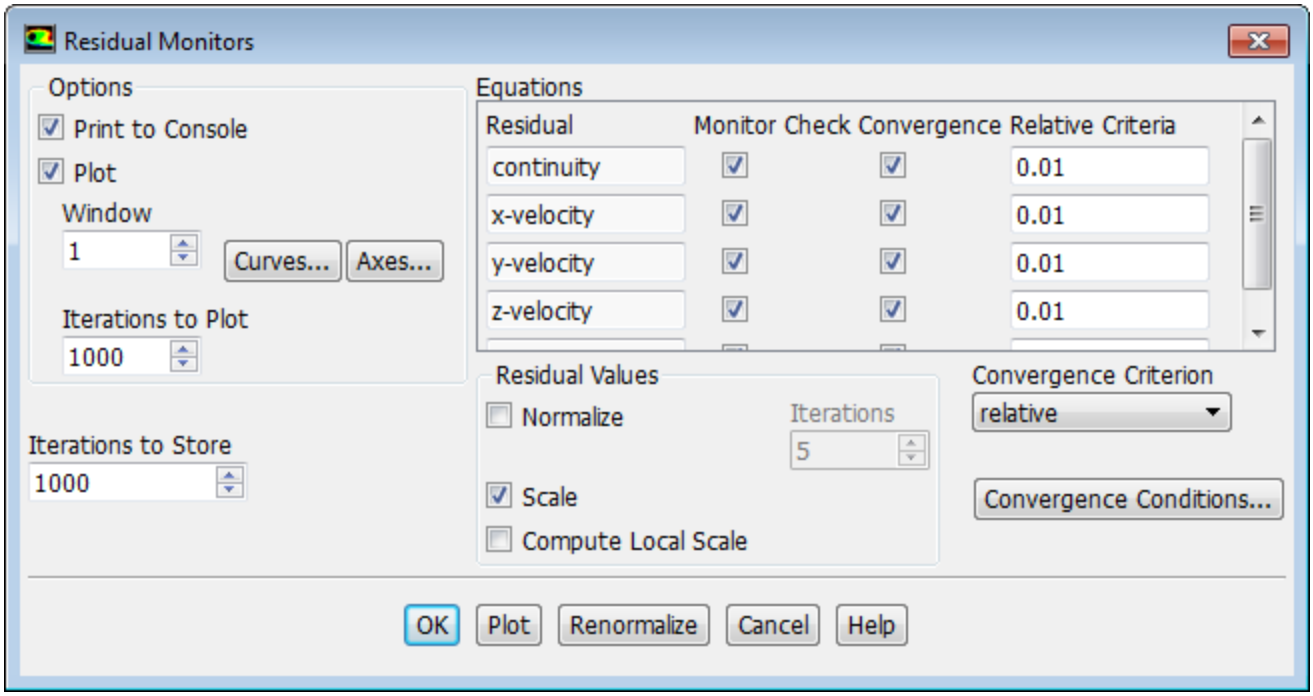
By default, $M=5$, making the normalized residual equivalent to the scaled residual. You can also specify the normalization factor (the denominator in Equation 28.14 (p. 1626)) manually in the Residual Monitors Dialog Box (p. 2789).

28.15.1.3. Overview of Using the Residual Monitors Dialog Box

All inputs controlling the monitoring of residuals are entered using the Residual Monitors Dialog Box (p. 2789)(Figure 28.32: The Residual Monitors Dialog Box (p. 1627)).

Solution → Monitors → Residuals Edit...

Figure 28.32: The Residual Monitors Dialog Box



In general, you will only need to enable residual plotting and modify the convergence criteria using this dialog box. Additional controls are available for disabling monitoring of particular residuals, and modifying normalization and plot parameters.

28.15.1.4. Printing and Plotting Residuals

By default, residual values for all relevant variables are printed in the console after each iteration. If you want to disable this printout, turn off **Print to Console** under **Options**. To enable the plotting of residuals after each iteration, turn on **Plot** under **Options**. Residuals will be plotted in the graphics window (with the window ID set in the **Window** field) during the calculation.

If you want to display a plot of the current residual history, simply click the **Plot** push button.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.15.1.5. Storing Residual History Points

Residual histories for each variable are automatically saved in the data file, regardless of whether they are being monitored. You can control the number of history points to be stored by changing the **Iterations to Store** entry. By default, up to 1000 points will be stored. If more than 1000 iterations are performed (that is, the limit is reached), every other point will be discarded—leaving 500 history points—and the next 500 points will be stored. When the total hits 1000 again, every other point will again be discarded, and so on. If you are performing a large number of iterations, you will lose a great deal of residual history information at the beginning of the calculation. In such cases, you should increase the **Iterations to Store** value to a more appropriate value. Of course, the larger this number is, the more memory you will need, the longer the plotting will take, and the more disk space you will need to store the data file.

28.15.1.6. Controlling Normalization and Scaling

By default, scaling of residuals (see Equation 28.6 (p. 1625) and Equation 28.12 (p. 1626)) is enabled and the default convergence criterion is 10^{-6} for energy and P-1 equations and 10^{-3} for all other equations. When the **Scale** option is enabled, global scaling will be applied by default. You can then enable the **Compute Local Scale** option and select the **Reporting Option** from the drop-down list. You have a choice to plot or print to the console the **local scaling** or the **global scaling** of residuals. By default, the **global scaling** of residuals will be plotted.

Note

When **Compute Local Scale** is enabled, ANSYS Fluent computes and stores both the locally and globally scaled residuals from subsequent iterations, for the purpose of reporting. The scaled residuals are stored in the data file.

Important

Once the **Compute Local Scale** option is enabled and you disable the **Scale** option, the **Compute Local Scale** option will not automatically be disabled. Instead, it will compute both the locally and globally scaled residuals, but only print or plot the unscaled residual.

Residual normalization (that is, dividing the residuals by the largest value during the first few iterations) is also available but disabled by default.

Normalization can be used with both scaled and unscaled residuals. Note that if normalization is enabled, the convergence criterion may need to be adjusted appropriately. See Judging Convergence (p. 1668) for information about judging convergence based on the different types of residual reports. (Both the raw residuals and scaling factors are stored in the data file, so you can switch between scaled and unscaled residuals.)

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To report unscaled residuals, simply disable the **Scale** option under **Residual Values**.

Important

If you switch from scaled to unscaled residuals (or vice versa) and you are normalizing the residuals (as described below), you must click the **Renormalize** button to recompute the normalization factors.

If you want to normalize the residuals (see Equation 28.10 (p. 1625) or Equation 28.14 (p. 1626)), enable the **Normalize** option under **Residual Values**. The **Normalization Factor** column will be added to the dialog box at this time. ANSYS Fluent will normalize the printed or plotted residual for each variable by the value indicated as the **Normalization Factor** for that variable. The default **Normalization Factor** is the maximum residual value after the first 5 iterations. To use the maximum residual value after a different number of iterations (that is, specify a different value for M in Equation 28.10 (p. 1625) or Equation 28.14 (p. 1626)), you can modify the **Iterations** entry under **Residual Values**.

In some cases, the maximum residual may occur sometime after the iteration specified in the **Iterations** field. If this should occur, you can click the **Renormalize** button to set the normalization factors for all variables to the maximum values in the residual histories. Subsequent plots and printed reports will use the new normalization factor.

You can also specify the normalization factor (the denominator in Equation 28.10 (p. 1625) or Equation 28.14 (p. 1626)) explicitly. To modify the normalization factor for a particular variable, enter a new value in the corresponding **Normalization Factor** field in the Residual Monitors Dialog Box (p. 2789).

If you want to report unnormalized, unscaled residuals (Equation 28.5 (p. 1624) or Equation 28.11 (p. 1626)), disable the **Normalize** and **Scale** options under **Residual Values** in the Residual Monitors Dialog Box (p. 2789). Note that unnormalized, unscaled residuals are stored in the data file regardless of whether the reported residuals are normalized or scaled.

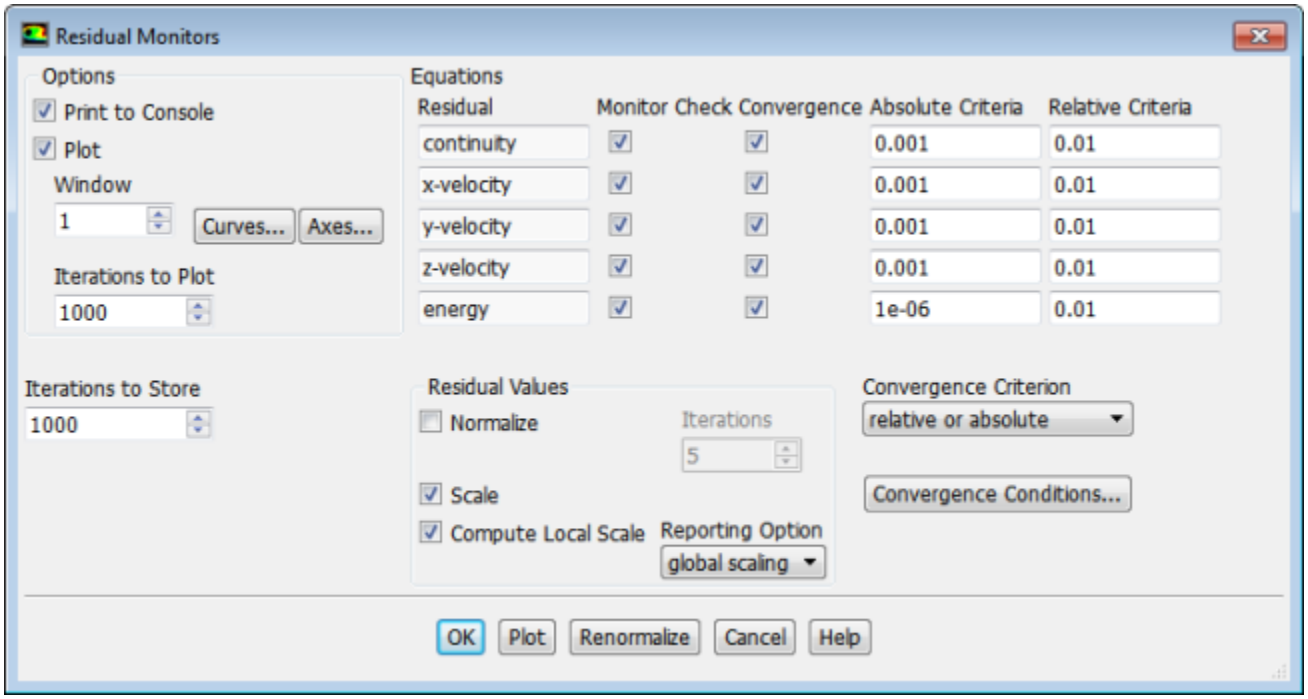
28.15.1.7. Choosing a Convergence Criterion

The ability to choose certain convergence criteria provides you with alternative ways to check convergence when using the iterative transient solver. The various convergence criteria can be selected in the **Residual Monitors** dialog box from the **Convergence Criterion** drop-down list.

Solution → **Monitors** → **Residuals** **Edit...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.33: The Residual Monitors Dialog Box Displaying Relative or Absolute Convergence



Four options are available for checking an equation for convergence:

absolute
This is the default. For steady-state cases, **absolute** and **none** are the only options available for selection. The residual (scaled and/or normalized) of an equation at an iteration is compared with a user-specified value. If the residual is less than the user-specified value, that equation is deemed to have converged for a time step.

relative
The residual of an equation at an iteration of a time step is compared with the residual at the start of the time step. If the ratio of the two residuals is less than a user-specified value, that equation is deemed to have converged for a time step.

relative or absolute
If either the **absolute** convergence criterion or the **relative** convergence criterion is met, the equation is considered converged.

The **Relative Criteria** can be set when **relative** or **relative or absolute** is selected.

none
Convergence checking is disabled.

In many situations, the **absolute** convergence criterion could be too stringent for transient flows causing a large number of iterations per time step. For example, the scaling of the continuity equation is based on the value of the continuity residual in the first five iterations. The scaling factor could be low if the initial continuity residual is small and therefore the scaled residual could fail to meet the **absolute** convergence criterion. With the **relative** convergence criterion, convergence is checked by comparing the residual at an iteration of a time step with the residual at the beginning of the time step and hence this problem is alleviated. The **relative or absolute** convergence criterion is useful in situations where the residuals of some of the equations are already very low at the start of a time step (for example, when a particular variable has reached steady-state), and the order of magnitude reduction in residuals

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

is not possible. The **none** option allows you to disable convergence checking by selecting the option in the **Convergence Criterion** drop-down list.

Important

relative and **relative or absolute** convergence criteria are available only with the unsteady pressure-based solver and unsteady density-based solver.

The text command used to access the convergence criterion is

`solve` → `monitors` → `residual` → `criterion-type`

When `criterion-type` is entered, you will have the following choices:

Criterion	Type
0	absolute
1	relative
2	relative or absolute
3	none

For `criterion-type` 1 or 2, the text command `relative-conv-criteria` will appear under the `residual` text menu, where the various `relative-conv-criteria` can be set.

Important

If the NITA solver is enabled, no convergence criteria are available for selection.

28.15.1.8. Modifying Convergence Criteria

Depending on the **Convergence Criterion** you choose, ANSYS Fluent will check for convergence. If convergence is being monitored, the solution will stop automatically when each variable meets its specified convergence criterion. Convergence checks can only be performed on variables whose residuals are being monitored (variables with the **Monitor** option enabled).

You can choose whether or not you want to check the convergence for each variable by enabling or disabling the **Check Convergence** option for it in the Residual Monitors Dialog Box (p. 2789). To modify the convergence criterion for a particular variable, enter a new value in the corresponding convergence criterion field.

28.15.1.9. Disabling Monitoring

If your problem requires the solution of many equations (for example, turbulence quantities and multiple species), a plot that includes all residuals may be difficult to read. In such cases, you may choose to monitor only a subset of the residuals, perhaps those that affect convergence the most. You can indicate whether or not you want to monitor residuals for each variable by enabling or disabling the relevant check box in the **Monitor** list of the Residual Monitors Dialog Box (p. 2789).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.15.1.10. Plot Parameters

If you choose to plot the residual values (either interactively during the solution or using the **Plot** button after calculations are complete), there are several display parameters you can modify.

In the **Window** field under **Options**, you can specify the ID of the graphics window in which the plot will be drawn. When ANSYS Fluent is iterating, the active graphics window is temporarily set to this window to update the residual plot, and then returned to its previous value. Thus, the residual plot can be maintained in a separate window that does not interfere with other graphical postprocessing.

You can modify the number of residual history points to be displayed in the plot by changing the **Iterations to Plot** entry under **Options**. If you specify n points, ANSYS Fluent will display the last n history points. Since the y axis is scaled by the minimum and maximum values of all points in the plot, you can zoom in on the end of the residual history by setting **Iterations to Plot** to a value smaller than the number of iterations performed. If, for example, the residuals jumped early in the calculation when you turned on turbulence, that peak broadens the overall range in residual values, making the smaller fluctuations later on almost indistinguishable. By setting the value of **Iterations to Plot** so that the plot does not include that early peak, your y-axis range is better suited to the values that you are interested in seeing. For more information on residual history points, refer to the discussion of storing residual history points, described earlier in this section.

You can also modify the attributes of the plot axes and the residual curves. Click the **Axes...** or **Curves...** button to open the Axes Dialog Box (p. 2608) or Curves Dialog Box (p. 2610). See Axes Dialog Box (p. 2608) and Curves Dialog Box (p. 2610) for details.

Important

Note that entering a value for **Iterations to Plot** does not necessarily mean *solved* iterations but rather *stored* (or sampled) data points. Note also that the frequency of the data storage will diminish towards the start of the solution as the number of solved iterations increases. Due to this, whenever the *stored* iterations is greater than the *solved* iterations, if you plot *n* iterations, you actually see a history that goes back further than *n* solved iterations.

28.15.1.11. Postprocessing Residual Values

If you are having solution convergence difficulties, it is often useful to plot the residual value fields (for example, using contour plots) to determine where the high residual values are located. When you use the density-based solver, the residual values for all solution variables are available in the **Residuals...** category in the postprocessing dialog boxes. (If you read case and data files into ANSYS Fluent, you will need to perform at least one iteration before the residual values are available for postprocessing.) For the pressure-based solver, however, only the mass imbalance in each cell is available by default.

Important

The residual values that are made available for postprocessing are the unscaled values.

If you want to plot residual value fields for a pressure-based solver calculation, you will need to do the following:

1. Read in the case and data files of interest (if they are not already in the current session).

2. Use the `expert` command in the `solve/set/` text menu to enable the saving of residual values.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

`solve` → `set` → `expert`

Among other questions, ANSYS Fluent will ask if you want to save cell residuals for postprocessing. Enter `yes` or `y`, and keep the default settings for all of the other questions (by pressing the <RETURN> key).

3. Perform at least one iteration.

The solution variables for which residual values are available will appear in the **Residuals...** category in the postprocessing dialog boxes. Note that residual values are *not* available for the radiative transport equations solved by the discrete ordinates radiation model.

28.15.2. Monitoring Statistics

If you are solving a fully-developed periodic flow, you may want to monitor the pressure gradient or the bulk temperature ratio, as discussed in Periodic Flows (p. 582).

If you are solving an unsteady flow (especially if you are using the explicit time stepping option), you may want to monitor the "time" that has elapsed during the calculation. The physical time of the flow field starts at zero when you initialize the flow. (See Performing Time-Dependent Calculations (p. 1608) for details about modeling unsteady flows.)

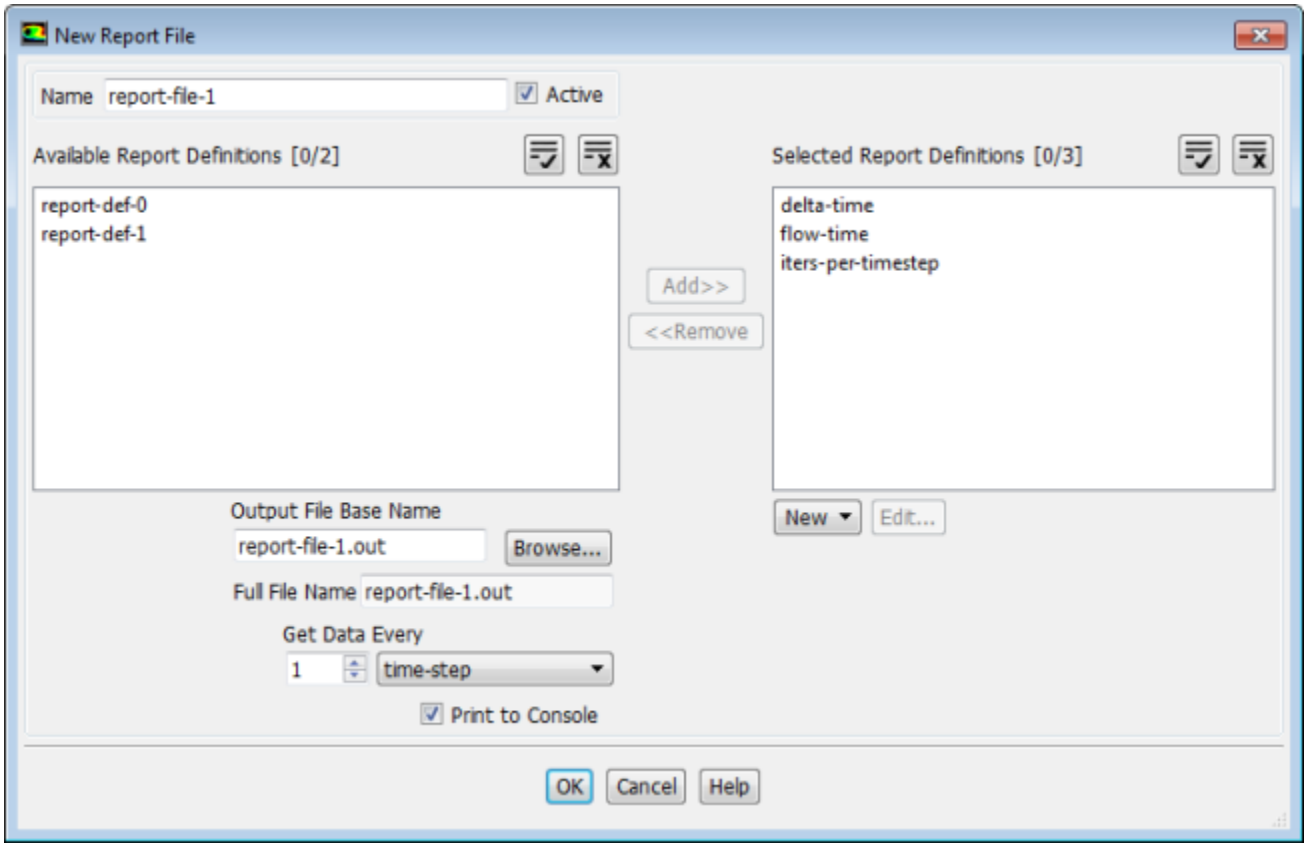
If you are using the adaptive time stepping method described in Adaptive Time Stepping (p. 1618), you may want to monitor the size of the time step, Δt.

You can create report files and plots for each of these quantities, flow-time, delta-time, and iterations-per-timestep, per-pr-grad (periodic pressure gradient), and per/bulk-temp-ratio (periodic bulk temperature ratio) or they can all be included in a single report file; flow-time and delta-time can be included in the same report plot.

Solution → **Monitors** → **Report File** **New...**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.34: Report File for 'flow-time', 'delta-time', and 'iters-per-timestep'



The procedure for setting up this monitor is listed below:

1. Indicate the type of report you want by enabling the **Print to Console** option for a printout and/or the **Plot** option for a plot.

2. Select the appropriate quantity in the **Statistics** list.

3. If you want to write the statistics to files, enable **Write**. Each selected statistic will be written to a file named with the base name listed in **File Basename** and the name of the statistic inserted immediately before the period. For example, if **File Basename** is set to `statistics-.out`, the **delta_time** statistic will be written to `statistics-delta_time.out`, the time statistic will be written to `statistics-time.out`, and so on.

4. Select whether to use **Iteration**, **Time Step**, or **Flow Time** for the **X Axis** quantity.

   Note

   The statistic monitors are evaluated, printed, plotted, and written according to the selection for **X Axis** — every iteration if **Iteration** is selected, and every time step otherwise. Thus, if you select **Time Step** or **Flow Time** and subsequently change to a steady-state solution, the monitor will not be evaluated unless you also change the **X Axis** setting back to **Iteration**.

5. If you are plotting the quantities, you can set any of the plotting options discussed below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.15.2.1. Plot Parameters

If you choose to plot the statistics, there are several display parameters you can modify.

In the **Window** field, you can specify the ID of the graphics window in which the plot will be drawn (or in which the first plot will be drawn, if you are plotting more than one quantity.) When ANSYS Fluent is iterating, the active graphics window is temporarily set to this window to update the plot, and then returned to its previous value. Thus, the statistics plot can be maintained in a separate window that does not interfere with other graphical postprocessing. Note that additional quantities that you have selected in the **Statistics** list will be plotted in windows with incrementally higher IDs.

You can also modify the attributes of the plot axes and curves. Click the **Axes...** or **Curves...** button to open the Axes Dialog Box (p. 2608) or Curves Dialog Box (p. 2610). See Axes Dialog Box (p. 2608) and Curves Dialog Box (p. 2610) for details.

28.15.3. Monitoring Solution Quantities

Solution quantities for which Report Definitions have been created can be monitored throughout the solution to aid in judging convergence. You can setup your case file so that force and moment coefficients and surface and volume integrals are computed and stored at the end of every iteration (for steady-state solutions) or time step (for transient solutions), and thereby create a convergence history. You can also choose to compute the value averaged over several iterations/time steps. Running averages can also help you determine if you have reached convergence for a solution that is oscillating or irregular. You can print and plot and save this convergence data to an external file using Report Files and Report Plots. The external file is written in the report file format described in Report Files and Report Plots (p. 1903).

Report Files and Report Plots are accessible under the **Monitors** node in the tree.

Solution → **Monitors** → **Report Files or Report Plots**

For additional information on setting up report definitions and report files and plots, see Monitoring and Reporting Solution Data (p. 1885) and Creating Report Definitions (p. 1886).

28.16. Convergence Conditions

The convergence conditions facility allows you to set convergence conditions on the solution that are based on the values from report definitions (surface, volume, lift, drag, and so on). There are two options for declaring convergence using report definitions:

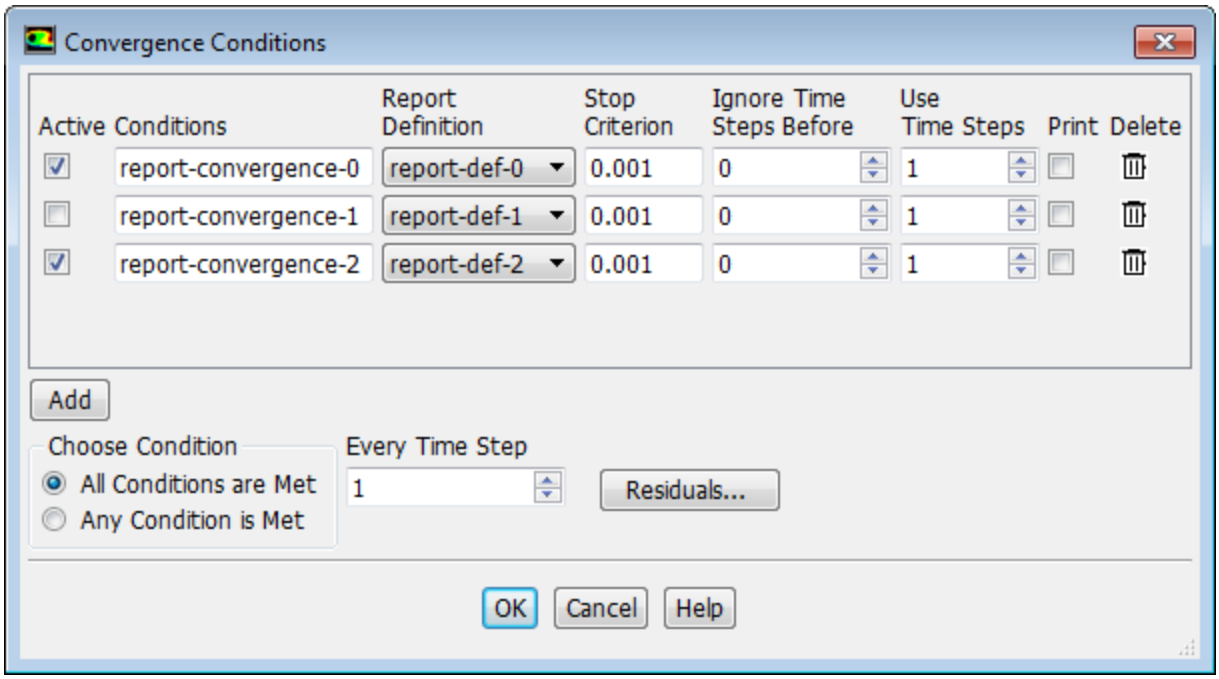
1. The solution is considered to be converged if all of the active report definitions' criteria are satisfied.

2. The solution is considered to be converged if any of the active report definitions' criteria is satisfied.

Convergence check for the report definitions is independent of that for the equation residuals. By default, the solution convergence will happen if either report definition convergence criteria or residuals convergence criteria is satisfied. If you want to rely only on the report definition values to decide convergence, clear the **Check Convergence** check boxes in the **Residual Monitors** dialog box.

To open the **Convergence Conditions** dialog box, click the **Convergence...** button in the **Solving** ribbon tab (**Reports** group box).

Solving → **Reports** → **Convergence...**



The **Active** column of check boxes (on the left) allows you to deactivate/activate convergence conditions.

28.16.1. Setting Up the Convergence Conditions Dialog Box

Create new convergence conditions by clicking **Add** and selecting a **Report Definition** from the drop-down list.

To create meaningful conditions for determining convergence from report definitions, set the levels of the convergence condition variables according to the following directions.

Enter a value in the **Ignore Iterations Before** column if you expect your solution to fluctuate in the first few iterations. Enter a value that represents the number of iterations you anticipate the fluctuations to continue. The calculation will begin after this number of iterations has finished.

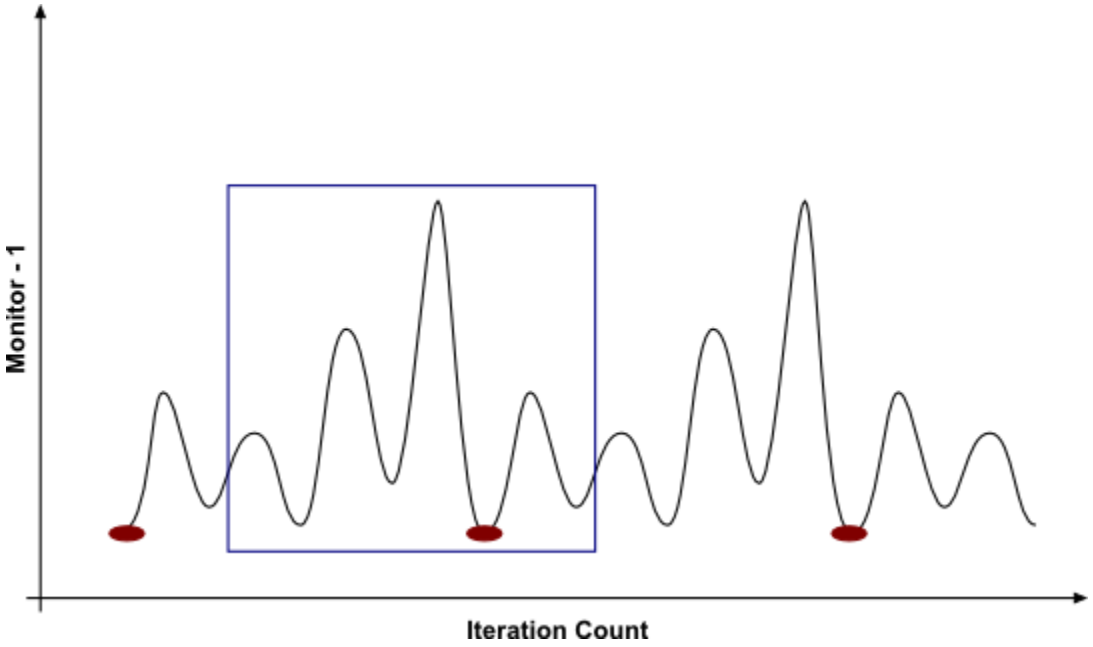
Use the **Use Iterations** setting to select the number of previous iterations to be included in the monitor convergence check. For fluctuating simulations like Figure 28.35: Fluctuating Simulation Example (p. 1637), this number should be high enough to counteract the effect of the fluctuations.

Note

Transient cases use time steps rather than iterations. When solving a transient case, the **Convergence Conditions** dialog box will relabel some fields: **Every Iteration** will change to **Every Time-step**, **Ignore Iterations Before** will change to **Ignore Time Steps Before**, and **Use Iterations** will change to **Use Time Steps**.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.35: Fluctuating Simulation Example



The **Stop Criterion** indicates the criterion below which the solution is considered to be converged. The value of **Stop Criterion** is calculated as follows:

Res-m(1) = [abs (m(n) - m(n-1))]/m(n)

Res-m(2) = [abs (m(n) - m(n-2))]/m(n)

Res-m(3) = [abs (m(n) - m(n-3))]/m(n)

.

.

.

Res-m(Np) = [abs (m(n) - m(n-Np))]/m(n)

Where:

Res-m is the report definition residual

n is the iteration number

m(n) is the value of the report definition at the n^{th} iteration

Np is the number of previous iterations to consider (**Use Iterations**/**Use Time Steps**)

The report definition residual is the absolute variance of the monitored quantity over the last Np iterations, divided by the current value of the monitored quantity.

If the maximum value of all of the Res-m values is less than the **Stop Criterion** number, the solution is considered to be converged at the n^{th} iteration. If the maximum value of all of the Res-m values is greater than or equal to the **Stop Criterion** number, the calculation will proceed to the next iteration.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Select the **Print** check box to print report definition residuals in the ANSYS Fluent console. These residuals are calculated as follows with respect to their immediate previous value only.

Pres-m(n) = [abs (m(n) - m(n-1))]/m(n)

Where:

Pres- m(n) is the printed residual value for a report definition

n is the iteration that is currently printed in the console

m(n) is the value of the monitor at the n^{th} iteration

Therefore:

Pres-m(n +1) = [abs (m(n+1) - m(n))]/m(n+1)

The printed value at the (n+1)th iteration is calculated with respect to the (n)th iteration and the printed value at the (n)th iteration is calculated with respect to the (n-1)th iteration.

28.17. Executing Commands During the Calculation

As described in Monitoring Solution Convergence (p. 1624) and Animating the Solution (p. 1647), respectively, you can report and monitor various quantities (for example, residuals, force coefficients) and create animations of the solution while the solver is performing calculations. ANSYS Fluent also includes a feature that allows you to define your own command(s) to be executed during the calculation at specified intervals. For example, you can ask ANSYS Fluent to perform gradient adaption after a set number of iterations. You will specify a series of text commands or use the GUI to define the steps to be performed.

Important

Note that the **Calculation Activities** task page provides options to perform the following during the calculation:

- save case and data files
- export transient solution files
- export transient particle history data files

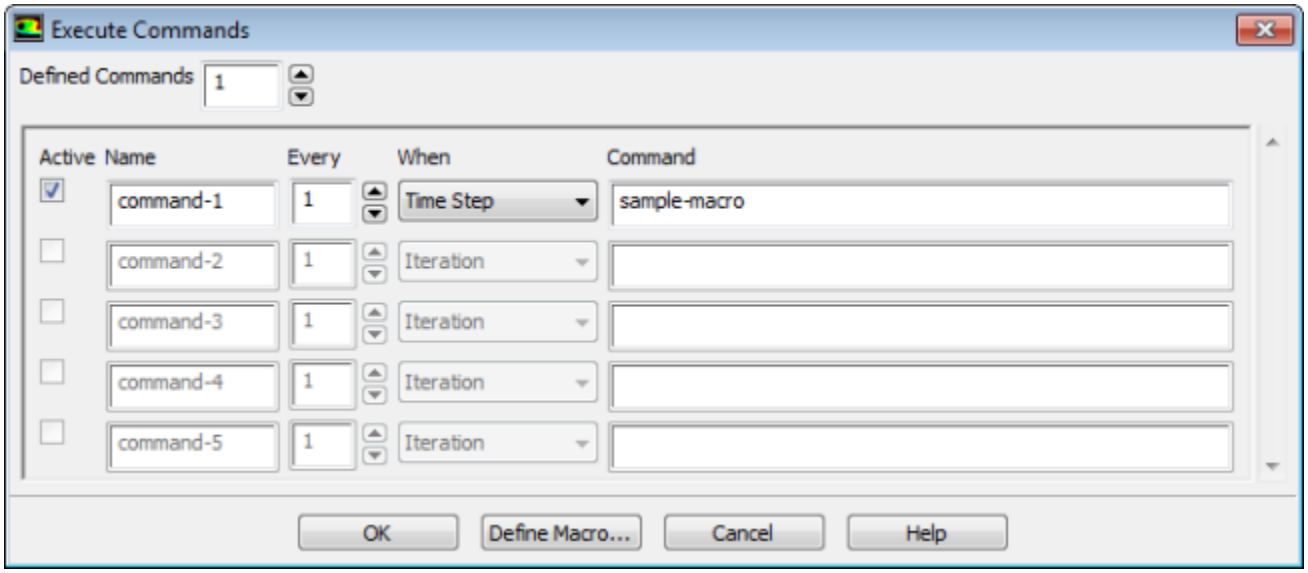
Each of these options has their own dialog box, which should be used rather than executing a command to perform them. See Automatic Saving of Case and Data Files (p. 48) and Exporting Data During a Transient Calculation (p. 86) for details.

You will indicate the command(s) that you want the solver to execute at specified intervals during the calculation using the Execute Commands Dialog Box (p. 2535) (Figure 28.36: The Execute Commands Dialog Box (p. 1639)).

Solution → Calculation Activities → Execute Commands → New...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.36: The Execute Commands Dialog Box



The procedure is as follows:

1. Increase the **Defined Commands** value to the number of commands you want to specify. As this value is increased, additional command entries will become editable. For each command, you will perform the following steps.

2. Enable the **Active** check button next to the command if you want it to be executed during the calculation. You may define multiple commands and choose to use only a subset of them by turning off the check button for those that you do not want to use.

3. Enter a name for the command under the **Name** heading.

4. Indicate how often you want the command to be executed by setting the interval under **Every** and selecting **Iteration** or **Time Step** in the drop-down list below **When**. (**Time Step** is a valid choice only if you are calculating unsteady flow.) For example, to execute the command every 10 iterations, you would enter `10` under **Every** and select **Iteration** under **When**.

Important

If you specify an interval in iterations, be sure to keep the **Reporting Interval** in the Run Calculation Task Page (p. 2537) at its default value of 1.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. Define the command by entering a series of text commands in the **Command** field, or by entering the name of a command macro you have defined (or will define) as described in Defining Macros (p. 1640).

Note

Make sure that the text commands you have entered in the **Command** field of the **Execute Commands** dialog box does not exceed 127 characters.

Important

- If the command to be executed involves saving a file, see Saving Files During the Calculation (p. 1642) for important information.
- If the command enables or disables equations, you must disable the convergence check for these equations.

For additional information, see the following sections:
28.17.1. Defining Macros
28.17.2. Saving Files During the Calculation

28.17.1. Defining Macros

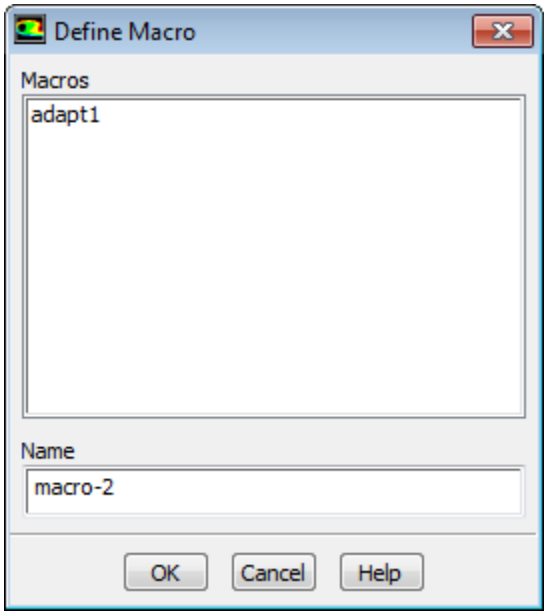
Macros that you define for automatic execution during the calculation can also be used interactively by you during the problem setup or postprocessing. For example, if you define a macro that performs a certain type of adaption after each iteration, you can also use the macro to perform this adaption interactively.

Definition of a macro is accomplished as follows:

1. In the Execute Commands Dialog Box (p. 2535), click the **Define Macro...** button to open the Define Macro Dialog Box (p. 2536) (Figure 28.37: The Define Macro Dialog Box (p. 1641)). Since this is a "modal" dialog box, the solver will not allow you to do anything else until you perform step 2, below.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.37: The Define Macro Dialog Box



2. In the **Define Macro** dialog box, specify a **Name** for the macro (for example, `adapt1`) and click **OK**. (The **Define Macro...** button in the **Execute Commands** dialog box will become the **End Macro** button.)

3. Perform the steps that you want the macro to perform. For example, if you want the macro to perform gradient adaption, open the **Gradient Adaption** dialog box, specify the appropriate adaption function and parameters, and click **Adapt** to perform the adaption.

   Important

   If the command to be executed involves saving a file, see Saving Files During the Calculation (p. 1642) for important information.

4. When you have completed the steps you want the macro to perform, click the **End Macro** button in the **Execute Commands** dialog box.

As noted above, once you have defined a macro for execution during the calculation, you can use it at any time. If you defined the macro called `adapt1` to adapt based on pressure gradient, you can simply type `adapt1` in the console to perform this adaption. This macro is independent of any text menus, so you need not move to a different text menu to use it. Macros can be saved to and read from files. To save all macros that are currently defined, use the `file/write-macros` text command. To read all the macros in a macro file, use the `file/read-macros` text command.

Important

A macro, like a journal file, is a simple record/playback function. It will therefore know nothing about the state in which it was recorded or the state in which it is being played back. You must be careful not to change directories while defining a macro. Also, you must be careful that all surfaces, variables, and so on, that are used by the macro have been properly defined when you (or ANSYS Fluent) invoke the macro.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.17.2. Saving Files During the Calculation

If the command to be executed during the calculation involves saving a file, you should include a special character in the file name when you enter it in The Select File Dialog Box (p. 19) so that the solver will know to assign a new name to each file it saves. See Automatic Numbering of Files (p. 43) for details about these special characters for filenames.

Important

Note that the **Calculation Activities** task page provides options to perform the following during the calculation:

- save case and data files
- export transient solution files
- export transient particle history data files

Each of these options has their own dialog box, which should be used rather than the **Execute Commands** dialog box. See Automatic Saving of Case and Data Files (p. 48) and Exporting Data During a Transient Calculation (p. 86) for details.

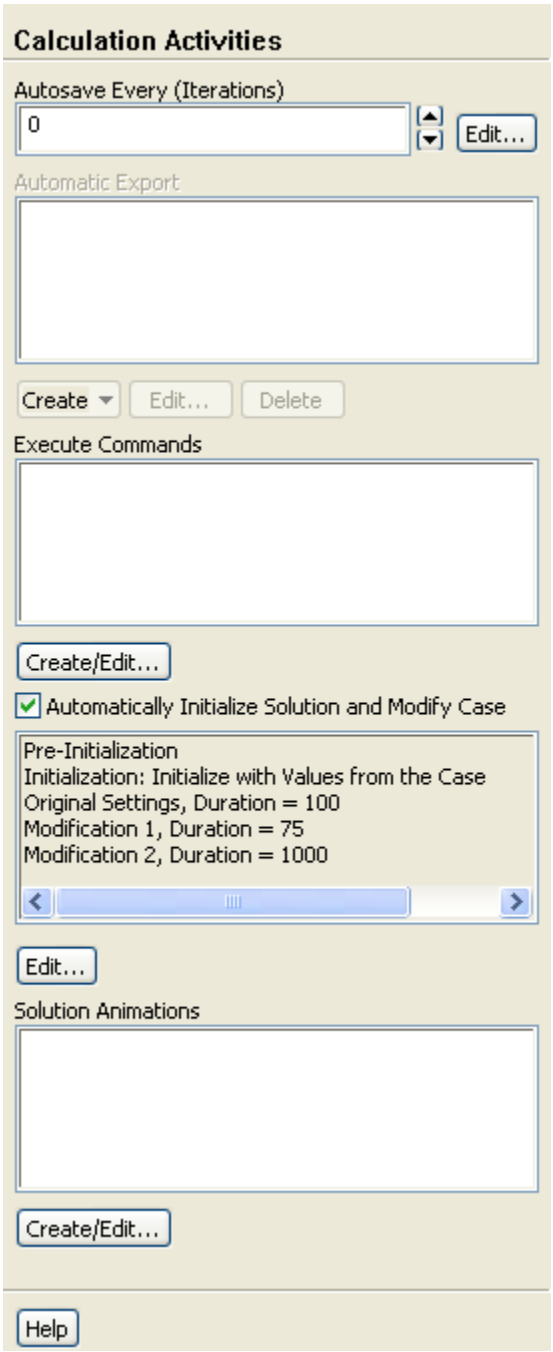
28.18. Automatic Initialization of the Solution and Case Modification

While running a case manually, you can perform certain activities that may facilitate convergence. These actions may take place before initialization, after initialization and/or at other points during the calculation. The process described in this section allows you to enter text commands at each of these times when a case is run from the **Run Calculation** task page, Workbench, or in batch. In the **Calculation Activities** task page, enable **Automatically Initialize Solution and Modify Case** to automatically modify the case.

Solution → Calculation Activities → Automatically Initialize Solution and Modify Case → Edit...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.38: The Automatically Initialize Solution and Modify Case Option



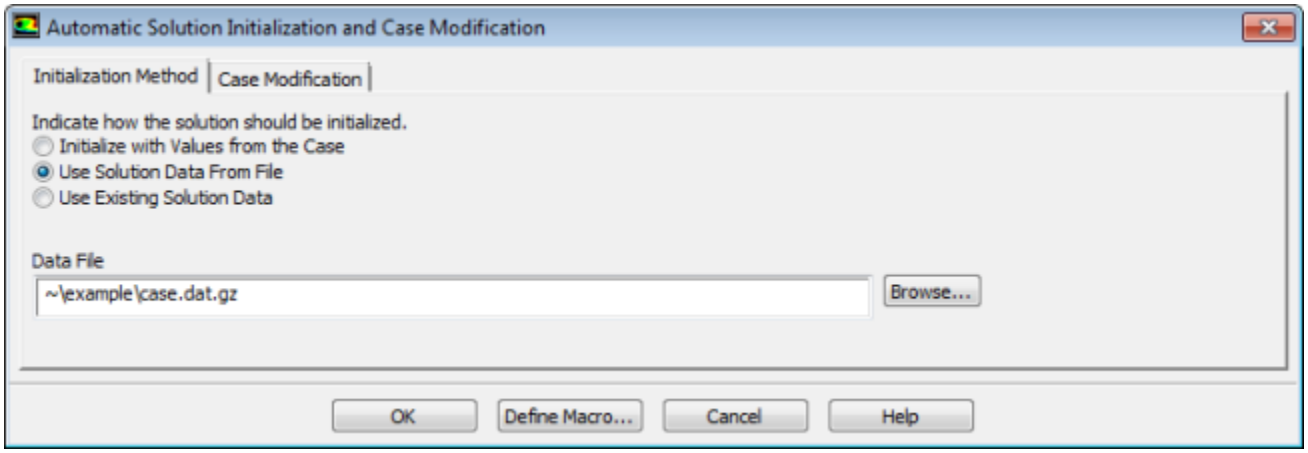
When using this option, you can edit the calculation settings. Note that the original settings always exist and cannot be deleted. The duration of the calculation is defined, so immediately after enabling **Automatically Initialize Solution and Modify Case**, you will notice that the **Calculation Activities** task page reports that the case will be run with the original settings for a single iteration.

You can now control the number of iterations or time steps for the calculation. When **Automatically Initialize Solution and Modify Case** option is disabled, you will have to specify the iterations or time steps using the **Run Calculation** task page.

For an uninitialized case, clicking the **Edit...** button will display the **Automatic Solution Initialization and Case Modification** dialog box, which allows you to specify the initialization method and to modify the case.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.39: The Automatic Solution Initialization and Case Modification Dialog Box



In the **Initialization Method** tab, you can specify four different initialization methods:

Initialize with Values from the Case
uses the values set in the **Solution Initialization** task page.

> **Note**
>
> Hybrid initialization is not performed for this option; even if you have selected **Hybrid Initialization** under the **Solution Initialization** task page.

Use Solution Data from File
requires you to read in a data file containing the desired initialization for this case, as shown in Figure 28.39: The Automatic Solution Initialization and Case Modification Dialog Box (p. 1644).

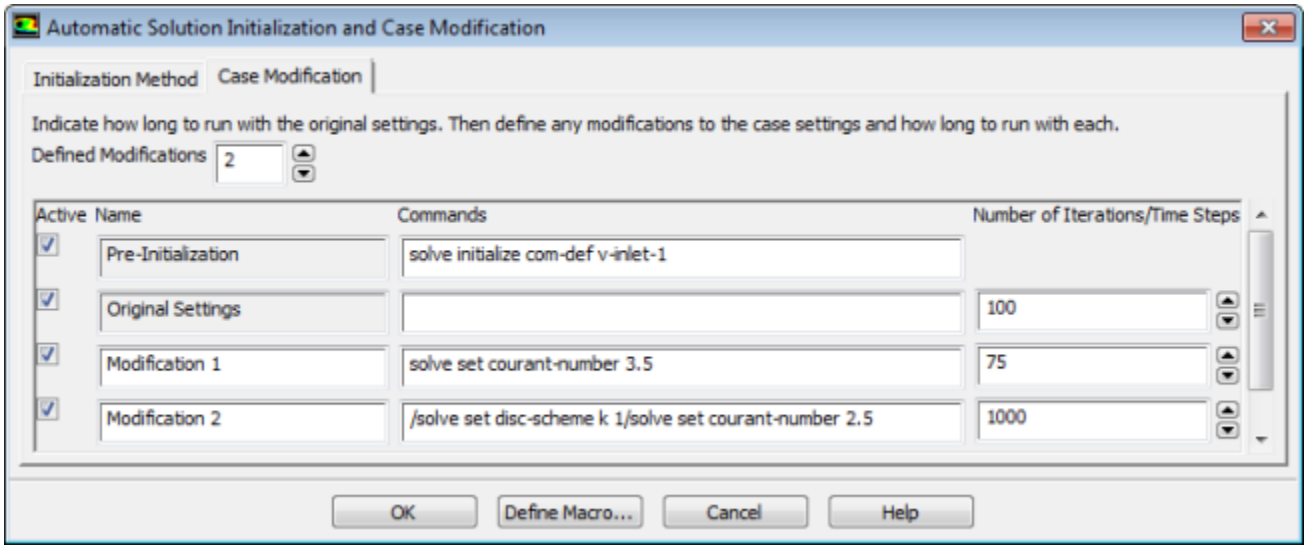
Use Existing Solution Data
is analogous to changing the values in a case and continuing the calculation. However, the iteration counter will be reset to 0 so that the modifications can be applied. Use this method when no solution data exists, similar to the first run.

> **Important**
>
> Whenever the case is initialized, the iteration count is set to 0.

In the **Case Modification** tab, you can indicate how long you would like to run with the original settings, then make any modifications to the case settings.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.40: The Case Modification Tab



If you decide to make no modifications, then the counter in the **Defined Modifications** box will be set to 0. However, you still have the option to specify settings that you would like to apply before initialization, or you can change your original settings. If **Before Initialization** is enabled, then you can type the text commands in the **Commands** field. If **Original Settings** is enabled, you can type text commands in the **Commands** field, and/or specify the **Number of Iterations/Time Steps**. When entering more than one text command in a single **Commands** field, begin each text command with a /, as shown in Figure 28.40: The Case Modification Tab (p. 1645).

Note

Make sure that the text commands you have entered in the **Commands** field does not exceed 127 characters.

Important

Note that some text commands require arguments (for example, numbers, file names, yes/no responses), which are requested through follow-up prompts in the console. When entering such text commands in the **Commands** field of the **Case Modification** tab, be sure to include your responses to the prompts. If you do not include these responses, the associated command will not be executed (unless it is a yes/no question, in which case ANSYS Fluent will use yes by default).

If you decide to run the calculation further with modifications to your case, increase the number of **Defined Modifications** and specify additional commands. The settings shown in Figure 28.40: The Case Modification Tab (p. 1645) result in the following actions:

1. The default initial values for initialization are computed from the velocity-inlet zone **inlet-6**.
2. The iteration count is set to 0 (in all situations) and the solution is initialized.
3. The calculation is run for 100 iterations or until convergence.
4. The Courant number is set to 3.5.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

5. The calculation continues for 75 iterations or until convergence.

6. The discretization scheme for turbulent kinetic energy is set to second order upwind, and the Courant number is set to 2.5.

7. The calculation continues for 1000 iterations or until convergence.

You can make the above changes sequentially and run your case, or you can specify them all at once. When you have completed making the modifications, click **OK**. A **Question** dialog box may appear, prompting you to take specific actions. For example, if the **Original Settings** field is empty, then you may be notified that the original settings will be lost if the case is saved after the modifications are applied. It will prompt you for a response when asked if you would like to add commands that specify the original settings.

Important

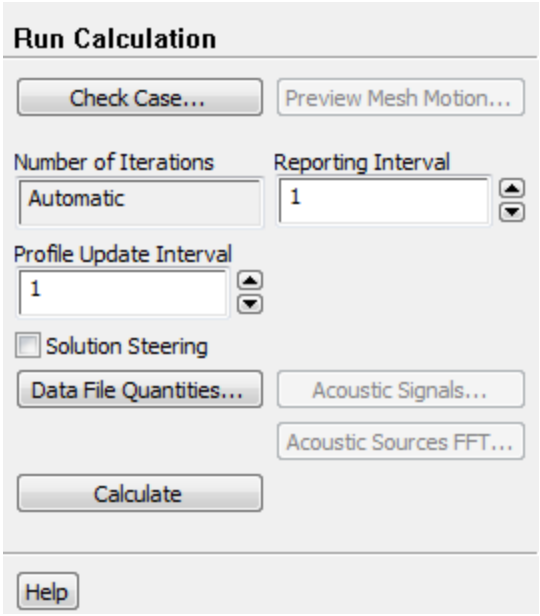
If you specify commands for the **Original Settings**, they will be applied to the case before the first iteration/time step.

Your actions will be summarized in the **Calculation Activities** task page, as shown in Figure 28.38: The Automatically Initialize Solution and Modify Case Option (p. 1643).

If you disable **Automatically Initialize Solution and Modify Case**, the settings will be disabled and retained, but will not be applied to the case.

When **Automatically Initialize the Solution and Modify the Case** is enabled, settings defined in the **Run Calculation** task page will be ignored. Instead, the **Number of Iterations** will be defined as **Automatic**, as shown in Figure 28.41: The Run Calculation Task Page (p. 1646).

Figure 28.41: The Run Calculation Task Page



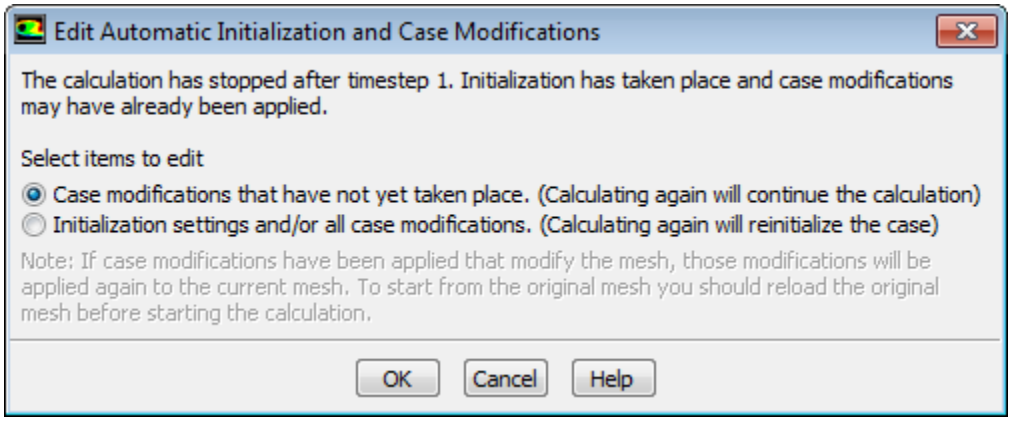
For additional information, see the following sections:
28.18.1. Altering the Solution Initialization and Case Modification after Calculating

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.18.1. Altering the Solution Initialization and Case Modification after Calculating

If you decide to edit the solution initialization and case modification settings and one or more iterations have been calculated, then clicking the **Edit...** button for the **Automatically Initialize Solution and Modify Case** option will open the **Edit Automatic Initialization and Case Modifications** dialog box, as shown in Figure 28.42: The Edit Automatic Initialization and Case Modifications Dialog Box (p. 1647).

Figure 28.42: The Edit Automatic Initialization and Case Modifications Dialog Box



If you select the first option, the initialization controls and modifications that have already taken place are disabled, therefore you can edit the case modifications that have yet to take place.

If you select the second option, all controls in the **Automatic Solution Initialization and Case Modification** dialog box are enabled and therefore, you can modify any of the settings.

28.19. Animating the Solution

During the calculation, you can have Fluent create an animation of mesh (primarily for dynamic mesh cases), contours, vectors, pathlines, particle tracks, scenes, XY plots, report plots, or residuals. Before you begin the calculation, you will specify and display the variables and types of plots you want to animate, and how often you want plots to be saved. At the specified intervals, Fluent will display the requested plots, and store each one. When the calculation is complete, you can play back the animation sequence, modify the view (for mesh, contour, vector, pathline, and particle tracks plots), if desired, and save the animation to a series of picture files or an MPEG file.

Instructions for defining a solution animation sequence are provided in Creating an Animation Definition (p. 1647). Playing an Animation Sequence (p. 1650) describes how to play back and save the animations.

For additional information, see the following sections:

28.19.1. Creating an Animation Definition
28.19.2. Playing an Animation Sequence
28.19.3. Saving an Animation Sequence
28.19.4. Reading an Animation Sequence

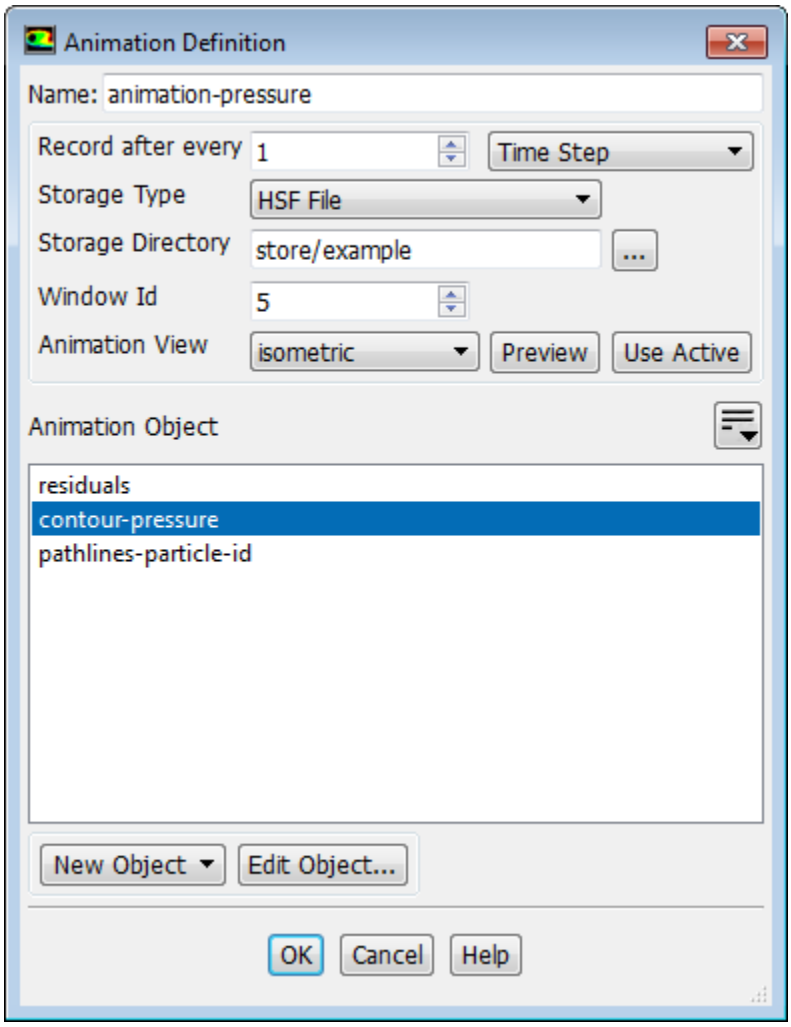
28.19.1. Creating an Animation Definition

You can use Figure 28.43: The Animation Definition Dialog Box (p. 1648) to specify the animation object and the frequency that it will be captured for animating.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Solving → Activities → Create → Solution Animations...

Figure 28.43: The Animation Definition Dialog Box



The procedure is as follows:

1. (Optional) Enter a **Name** for the animation definition.

2. Indicate how often you want to create a new frame in the animation by specifying a frequency in **Record after every** and selecting **Iteration** or **Time Step**.

3. Specify how you want Fluent to save the animation frames by selecting **In Memory**, **PPM Image** (2D image file), or **HSF File** (3D image file) from the **Storage Type** drop-down.

Important

The advantage to saving the animation sequence using the **HSF File** option is that these files are highly compressible and can be viewed and interacted with using a "HOOPS Viewer" application on iOS and Android equipped devices. The "HOOPS Viewer" application can be downloaded to iOS and Android equipped devices from the "App Store" and "Google Play" respectively.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

An advantage to saving the animation sequence using the **PPM Image** option is that you can use the separate pixmap image files for the creation of a single GIF file. GIF file creation can be done quickly with graphics tools provided by other third-party graphics packages such as ImageMagick, that is, `animate` or `convert`. For example, if you save the PPM files starting with the string `sequence-2`, and you are using the ImageMagick software, you can use the `convert` command with the `-adjoin` option to create a single GIF file out of the sequence using the following command.

```
convert -adjoin sequence-2_00*.ppm sequence2.gif
```

4. Choose the **Storage Directory** where Fluent save the animation frames.

5. (Optional) Specify the graphics **Window ID** where the animation frames will be displayed during the calculation.

6. (Optional) Specify the **Animation View**, which determines the orientation of the object for the animation frames captured during the calculation.

   *You can only specify the view once an **Animation Object** is selected*. Clicking **Preview** displays the selected object in the graphics window specified by **Window ID**, with the view shown in the drop-down. If your desired view is not available in the drop-down, you can preview the object, change its orientation in the graphics window, then click **Use Active** to save the current graphics window view and use it for this animation definition.

7. Select the graphics object you want to animate from the **Animation Object** list. If you want to animate an object that is not listed, you can create a **New Object**.

   - **Mesh...** opens the Mesh Display Dialog Box (p. 2163).
   - **Contours...** opens the Contours Dialog Box (p. 2676).
   - **Vectors...** opens the Vectors Dialog Box (p. 2831).
   - **Pathlines...** opens the Pathlines Dialog Box (p. 2771).
   - **Particle Tracks...** opens the Particle Tracks Dialog Box (p. 2761).
   - **Scene...** opens Figure 31.26: The Scene Dialog Box (p. 1781).
   - **XY Plot...** opens the Solution XY Plot Dialog Box (p. 2595).
   - **Report Plot...** opens the New Report Plot Dialog Box (p. 2755).

8. Click **OK** to create the animation definition.

28.19.1.1. Guidelines for Creating an Animation Definition

If you are defining an animation sequence containing mesh, contour, or vector displays, note the following when you are defining the display:

- If you want to include lighting effects in the animation frames, be sure to define the lights before you begin the calculation. See Adding Lights (p. 1796) for information about adding lights to the display.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- If you want to maintain a constant range of colors in a contour or vector display, you can specify a range explicitly by turning off the **Auto Range** option in the **Contours** or **Vectors** dialog box. See Specifying the Range of Magnitudes Displayed (p. 1759) or Specifying the Range of Magnitudes Displayed (p. 1768) for details.

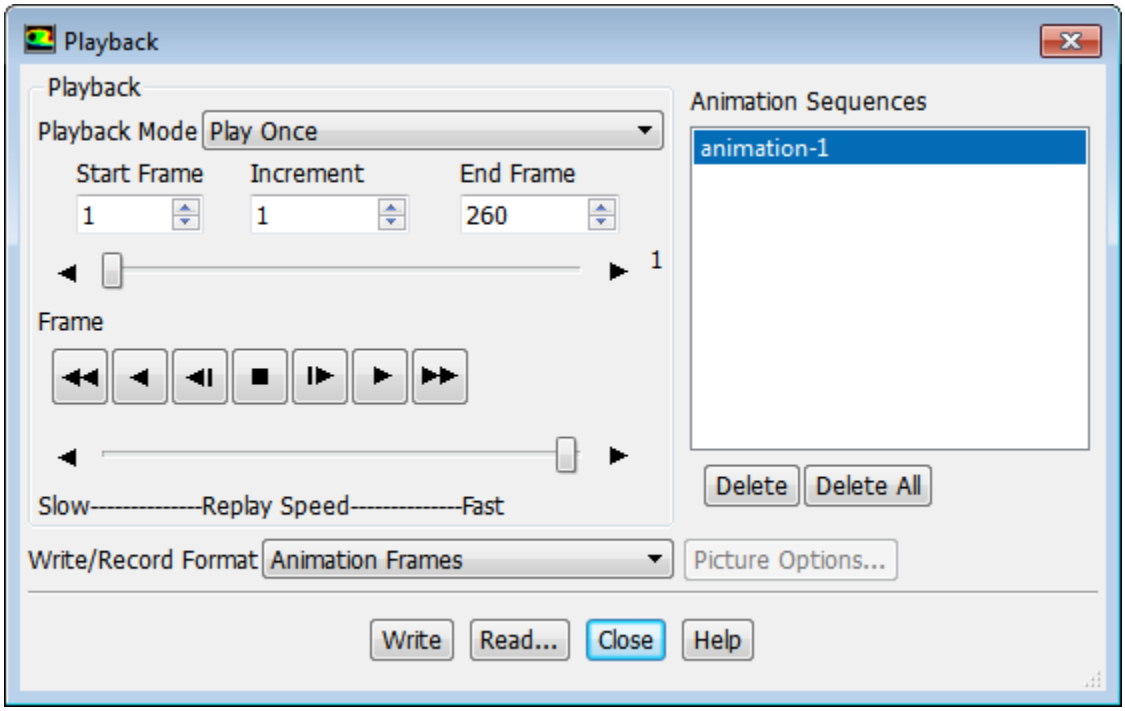
- Advanced scene manipulations that are specified using the **Scene Description** dialog box will *not* be included in the animation sequence frames. View modifications such as mirroring across a symmetry plan *will* be included.

28.19.2. Playing an Animation Sequence

Once you have defined a sequence (as described in Creating an Animation Definition (p. 1647)) and performed a calculation, or read in a previously created animation sequence (as described in Reading an Animation Sequence (p. 1654)), you can play back the sequence using the Playback Dialog Box (p. 2571) (Figure 28.44: The Playback Dialog Box (p. 1650)).

Results → Animations → Solution Animation Playback Edit...

Figure 28.44: The Playback Dialog Box



Under **Animation Sequences** in the **Playback** dialog box, select the sequence you want to play in the **Sequences** list. To play the animation once through from start to finish, click the "play" button under the **Playback** heading. (The buttons function in a way similar to those on a standard video cassette player. "Play" is the second button from the right—a single triangle pointing to the right.) To play the animation backwards once, click the "play reverse" button (the second from the left—a single triangle point to the left). As the animation plays, the **Frame** scale shows the number of the frame that is currently displayed, as well as its relative position in the entire animation. If, instead of playing the complete animation sequence, you want to jump to a particular frame, move the **Frame** slider bar to the desired

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

frame number, and the frame corresponding to the new frame number will be displayed in the graphics window.

Important

For smoother animations, enable the **Double Buffering** option in the Display Options Dialog Box (p. 2573) (see Modifying the Rendering Options (p. 1798)). This will reduce screen flicker during graphics updates.

Additional options for playing back animations are described below.

28.19.2.1. Modifying the View

If you want to replay the animation sequence with a different view of the scene, you can use your mouse to modify (for example, translate, rotate, zoom) it in the graphics window where the animation is displayed. Note that any changes you make to the view for an animation sequence will be lost when you select a new sequence (or reselect the current sequence) in the **Sequences** list.

28.19.2.2. Modifying the Playback Speed

Different computers will play the animation sequence at different speeds, depending on the complexity of the scene and the type of hardware used for graphics. You may want to slow down the playback speed for optimal viewing. Move the **Replay Speed** slider bar to the left to reduce the playback speed (and to the right to increase it).

28.19.2.3. Playing Back an Excerpt

You may sometimes want to play only one portion of a long animation sequence. To do this, you can modify the **Start Frame** and the **End Frame** under the **Playback** heading. For example, if your animation contains 50 frames, but you want to play only frames 20 to 35, you can set **Start Frame** to 20 and **End Frame** to 35. When you play the animation, it will start at frame 20 and finish at frame 35.

28.19.2.4. "Fast-Forwarding" the Animation

You can "fast-forward" or "fast-reverse" the animation by skipping some of the frames during playback. To fast-forward the animation, you will need to set the **Increment** and click the fast-forward button (the last button on the right—two triangles pointing to the right). If, for example, your **Start Frame** is 1, your **End Frame** is 15, and your **Increment** is 2, when you click the fast-forward button, the animation will show frames 1, 3, 5, 7, 9, 11, 13 and 15. Clicking on the fast-reverse button (the first button on the left—two triangles pointing to the left) will show frames 15, 13, 11,...1.

28.19.2.5. Continuous Animation

If you want the playback of the animation to repeat continuously, there are two options available. To continuously play the animation from beginning to end (or from end to beginning, if you use one of the reverse play buttons), select **Auto Repeat** in the **Playback Mode** drop-down list. To play the animation back and forth continuously, reversing the playback direction each time, select **Auto Reverse** in the **Playback Mode** drop-down list.

To turn off the continuous playback, select **Play Once** in the **Playback Mode** list. This is the default setting.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.19.2.6. Stopping the Animation

To stop the animation during playback, click the "stop" button (the square in the middle of the playback control buttons). If your animation contains very complicated scenes, there may be a slight delay before the animation stops.

28.19.2.7. Advancing the Animation Frame by Frame

To advance the animation manually frame by frame, use the third button from the right (a vertical bar with a triangle pointing to the right). Each time you click this button, the next frame will be displayed in the graphics window. To reverse the animation frame by frame, use the third button from the left (a left-pointing triangle with a vertical bar). Frame-by-frame playback allows you to freeze the animation at points that are of particular interest.

28.19.2.8. Deleting an Animation Sequence

If you want to remove one of the sequences that you have created or read in, select it in the **Sequences** list and click the **Delete** button. If you want to delete all sequences, click the **Delete All** button.

Important

Note that if you delete a sequence that has not yet been saved to disk (that is, if you selected **In Memory** under **Storage Type** in the **Animation Sequence** dialog box), it will be removed from memory permanently. If you want to keep any animation sequences that are stored only in memory, you should be sure to save them (as described in Saving an Animation Sequence (p. 1652)) before you delete them from the **Sequences** list or exit ANSYS Fluent.

28.19.3. Saving an Animation Sequence

Once you have created an animation sequence, you can save it in any of the following formats:

- Solution animation file containing the ANSYS Fluent metafiles
- Picture files, each containing a frame of the animation sequence
- MPEG file containing each frame of the animation sequence

Note that, if you are saving picture files or an MPEG file, you can modify the view (for example, translate, rotate, zoom) in the graphics window where the animation is displayed, and save the modified view instead of the original view.

28.19.3.1. Solution Animation File

If you selected **HSF File** or **PPM Image** for **Storage Type** in Figure 28.43: The Animation Definition Dialog Box (p. 1648), then Fluent will save the solution animation file for you automatically. It will be saved in the specified **Storage Directory**, and its name will be the **Name** you specified for the sequence, with a `.cxa` extension (for example, `pressure-contour.cxa`). In addition to the `.cxa` file, Fluent will also save image files with `.hsf` or `.ppm` extensions for each frame (for example, `pressure-contour_0002.hsf`). The `.cxa` file contains a list of the associated `.hsf` or `.ppm` files, and tells Fluent the order in which to display them.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

If you selected **In Memory** under **Storage Type**, then the solution animation file (`.cxa`) and the associated files (`.hmf`) will be lost when you exit from ANSYS Fluent, unless you save them as described below.

You can save the animation sequence to a file that can be read back into ANSYS Fluent (see Reading an Animation Sequence (p. 1654)) when you want to replay the animation. As noted in Reading an Animation Sequence (p. 1654), the solution animation file can be used for playback in Fluent independent of the case and data files that were used to generate it.

To save a solution animation file (and the associated files), select **Animation Frames** in the **Write/Record Format** drop-down list in the **Playback** dialog box, and click the **Write** button. ANSYS Fluent will save a `.cxa` file, as well as a `.hmf` file for each frame of the animation sequence. The filename for the `.cxa` file will be the specified sequence **Name** (for example, `pressure-contour.cxa`), and the file names for the metafiles will consist of the specified sequence **Name** followed by a frame number (for example, `pressure-contour_0002.hmf`). All of the files (`.cxa` and `.hmf`) will be saved in the current working directory.

28.19.3.2. Picture File

You can also generate a picture file for each frame in the animation sequence. This feature allows you to save your sequence frames to picture files used by an external animation program such as ImageMagick. As noted above, you can modify the view in the graphics window before you save the picture files.

To save the animation as a series of picture files, follow these steps:

1. Select **Picture Files** in the **Write/Record Format** drop-down list in the **Playback** dialog box.

2. If necessary, click the **Picture Options...** button to open the Save Picture Dialog Box (p. 2568) and set the appropriate parameters for saving the picture files. (If you are saving picture files for use with ImageMagick, for example, you may want to select the window dump format. See Window Dumps (Linux Systems Only) (p. 106) **Apply** in the **Save Picture** dialog box to save your modified settings.

   Important

   Do not click the **Save...** button in the **Save Picture** dialog box. You will save the picture files from the **Playback** dialog box in the next step.

3. In the **Playback** dialog box, click the **Write** button. ANSYS Fluent will replay the animation, saving each frame to a separate file. The filenames will consist of the specified sequence **Name** followed by an animation sequence and a frame number (for example, `pressure-contour_1_0002.ps`), and they will all be saved in the current working directory.

28.19.3.3. MPEG File

It is also possible to save all of the frames of the animation sequence in an MPEG file, which can be viewed using an MPEG decoder such as **mpeg_play**. Saving the entire animation to an MPEG file will require less disk space than storing individual window dump files (using the picture method), but the MPEG file will yield lower-quality images.

As noted above, you can modify the view in the graphics window before you save the MPEG file.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

To save the animation to an MPEG file, follow these steps:

1. Select **MPEG** in the **Write/Record Format** drop-down list in the **Playback** dialog box.

2. Click the **Write** button.

   ANSYS Fluent will replay the animation and save each frame to a separate scratch file, and then it will combine all the files into a single MPEG file. The name of the MPEG file will be the specified sequence **Name** with an `.mpg` extension (for example, `pressure-contour.mpg`), and it will be saved in the current working directory.

28.19.4. Reading an Animation Sequence

If you have saved an animation sequence to a solution animation file (as described in Saving an Animation Sequence (p. 1652)), you can read that file back in at a later time (or in a different session) and play the animation. Note that you can read a solution animation file into any ANSYS Fluent session; you do not need to read in the corresponding case and data files. In fact, you do not need to read in any case and data files at all before you read a solution animation file into ANSYS Fluent.

To read a solution animation file, click the **Read...** button in the Playback Dialog Box (p. 2571). In The Select File Dialog Box (p. 19), specify the name of the file to be read.

28.20. Checking Your Case Setup

After you have set up your case, and prior to solving it, you can check your case setup using the Case Check Dialog Box (p. 2543) (Figure 28.45: The Case Check Dialog Box (p. 1655)). This function provides you with guidance and best practices when choosing case parameters and models. Your case will be checked for compliance in the mesh, models, boundary and cell zone conditions, material properties, and solver categories. Established rules will be available for each category, with recommended changes to your current settings. At your discretion, you may elect to apply the recommendations, or keep your current settings.

To access the Case Check Dialog Box (p. 2543) (Figure 28.45: The Case Check Dialog Box (p. 1655)), go to

Solution → **Run Calculation** → **Check Case...**

If there are no problems with your case setup, then an information dialog box (Figure 28.46: The Information Dialog Box (p. 1655)) will appear stating that no recommendations need to be made at this time, otherwise, the Case Check Dialog Box (p. 2543) will open.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.45: The Case Check Dialog Box

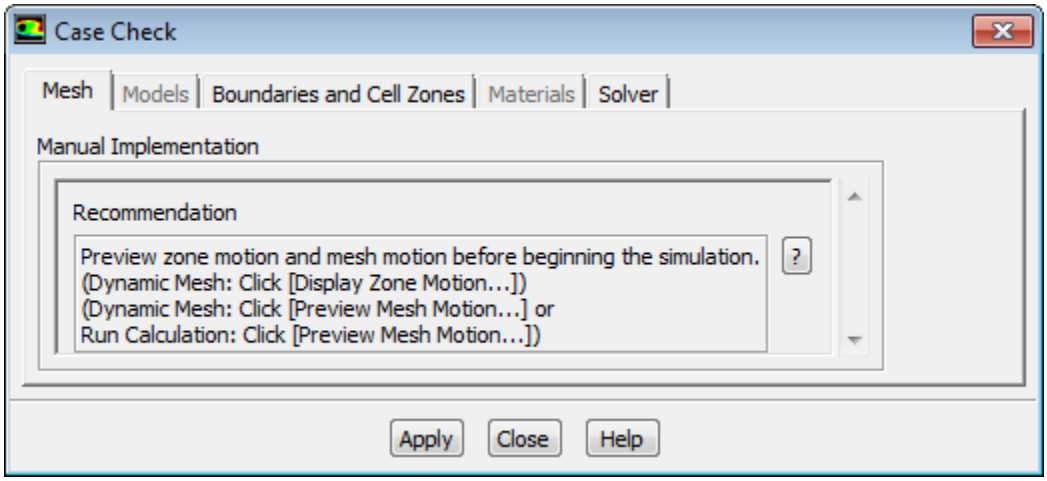


Figure 28.46: The Information Dialog Box

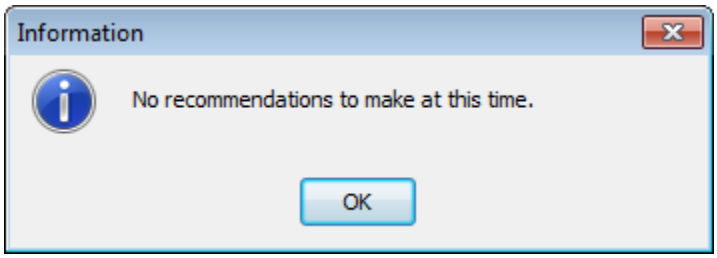


In the **Case Check** dialog box, each of the tabs **Mesh**, **Models**, **Boundaries and Cell Zones**, **Materials**, and **Solver** may contain recommendations. For each of the tabs that are enabled, best practices will be listed.

In some cases, the dialog box will be split based on the method that the recommendation is applied. There are two ways you can apply the listed recommendations:

Automatic Implementation
ANSYS Fluent applies the change for you.

Manual Implementation
You will manually change your case settings.

For additional information, see the following sections:
28.20.1. Automatic Implementation
28.20.2. Manual Implementation

28.20.1. Automatic Implementation

To the left of each of the recommendations listed under **Automatic Implementation** (for example, Figure 28.48: The Models Tab in the Case Check Dialog Box (p. 1659)), there is an enabled **Apply** check box. An enabled check box will result in ANSYS Fluent applying the change to your case automatically. If there are some recommendations that you do not want ANSYS Fluent to implement automatically, then click the **Apply** check box to toggle off and disable the implementation of a particular recommendation. After going through all the tabs and determining which rules you want applied automatically, click the **Apply** button at the bottom of the dialog box. Changes to your settings will be applied to all

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

recommendations throughout the dialog box with an enabled **Apply** check box. ANSYS Fluent will print a message in the console notifying you that the applied recommendation has been implemented.

ANSYS Fluent will ask you if you want to save the case before proceeding to the next step. If you choose **Yes**, The Select File Dialog Box (p. 19) will open allowing you to save your case with the new settings. If you select **No**, all the changes made to the case file will be lost once you exit ANSYS Fluent.

28.20.2. Manual Implementation

For recommendations that are listed under **Manual Implementation**, ANSYS Fluent cannot apply the changes for you. Therefore, if you opt to make a change to your current settings, based on the listed recommendations, then you will need to manually make the changes by opening the affected dialog boxes or task pages and applying what was recommended.

To the right of the recommendations is a **?**, which essentially acts as a help button, leading you to related documentation on the specific topic.

At the bottom of each recommendation, there is a path that will guide you to the dialog box or task page where you can make the changes. For example, in the **Mesh** tab, you will see the following recommendation:

```
Check your mesh.
(General: Click [Check])
```

To perform the action, highlight **General** in the tree, then click the **Check** button in the **Mesh** group box. You will see a path for each recommendation, in each of the tabs.

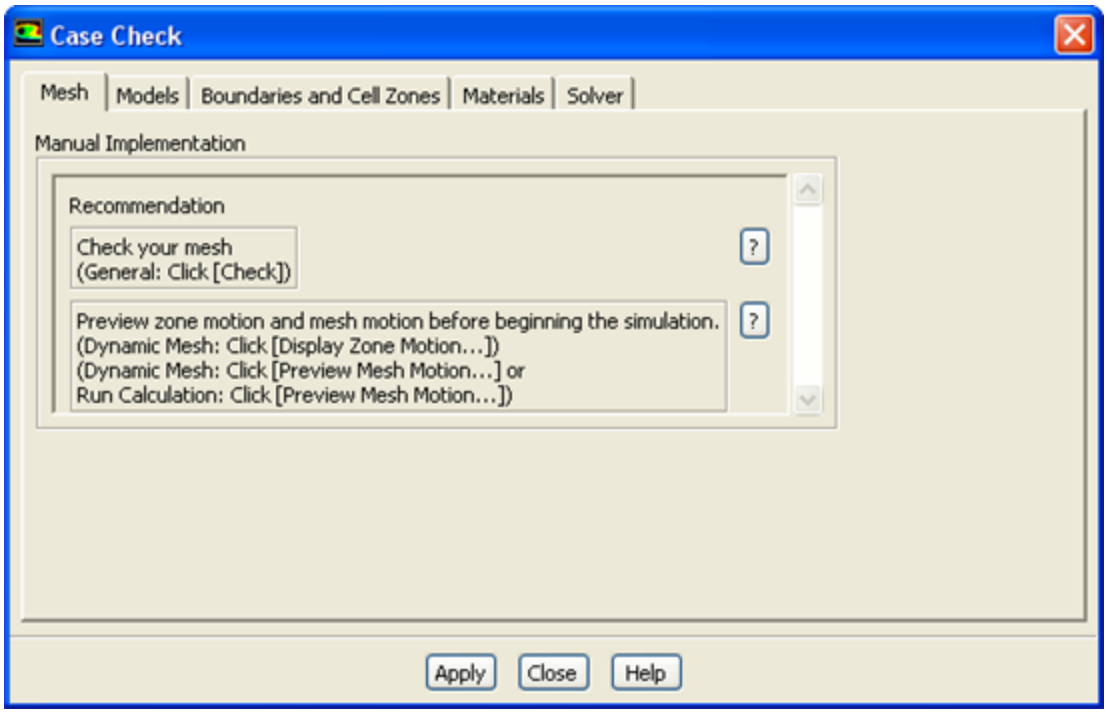
Each of the case check rules are described in the following sections:

28.20.2.1. Checking the Mesh
28.20.2.2. Checking Model Selections
28.20.2.3. Checking Boundary and Cell Zone Conditions
28.20.2.4. Checking Material Properties
28.20.2.5. Checking the Solver Settings

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.20.2.1. Checking the Mesh

Figure 28.47: The Mesh Tab in the Case Check Dialog Box



The following recommendations appear under the **Mesh** tab (Figure 28.47: The Mesh Tab in the Case Check Dialog Box (p. 1657)):

- **Check your mesh.**

  If you have not already checked your mesh, it is best practice that you do so immediately after reading in your mesh, or after any mesh modification. To check your mesh go to

  Setup → General → Check

  Checking the mesh will help you detect any mesh trouble before you get started with your problem setup. You can learn more about the information obtained when checking your mesh, by going to Checking the Mesh (p. 192).

- **Improve the mesh quality before proceeding with your simulation. The maximum cell skewness is greater than 0.98.**

  Check the quality of your mesh immediately after reading in your mesh, or after any mesh modification. The quality of the mesh plays a significant role in the accuracy and stability of the numerical computation. You can learn more about the quality of your mesh by going to Mesh Quality (p. 131).

  Setup → General → Report Quality

- **Preview zone motion and mesh motion before beginning the simulation.**

  After setting up your case using the **Dynamic Mesh** model, it is worth while to preview your mesh prior to running your simulation. You can preview **Zone Motion** by going to

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Dynamic Mesh → Dynamic Mesh → Display Zone Motion...

To preview the **Mesh Motion**, go to

Setup → Dynamic Mesh → Dynamic Mesh → Preview Mesh Motion...

or

Solution → Run Calculation → Preview Mesh Motion... **Solution → Run Calculation → Preview Mesh Motion...**

It is important that you preview zone motion first and then mesh motion. Zone motion shows the motion of all dynamic zones with the prescribed rigid body motion, using the graphics library. It is a very fast process and does not alter the mesh. Previewing the zone motion will show you if the motion is set up properly (for example zones moving in the wrong direction or rotating about the wrong center). It is much more difficult to detect these problems with mesh motion because small time steps are performed and no continuous animation is shown.

Mesh motion should always be done for dynamic mesh cases with prescribed motion. Mesh motion will only show the validity of the mesh during the simulation. Mesh deformation and dynamic zones without rigid body motion will be considered during a mesh motion preview.

Both the **Mesh Motion** and **Zone Motion** dialog boxes will have a **Preview** button that will allow you to view the mesh or zone motion prior to running your case. You can obtain more information on mesh motion and zone motion by going to Previewing the Dynamic Mesh (p. 742).

- **Translate the mesh for axisymmetric geometry containing nodes below the x-axis.**

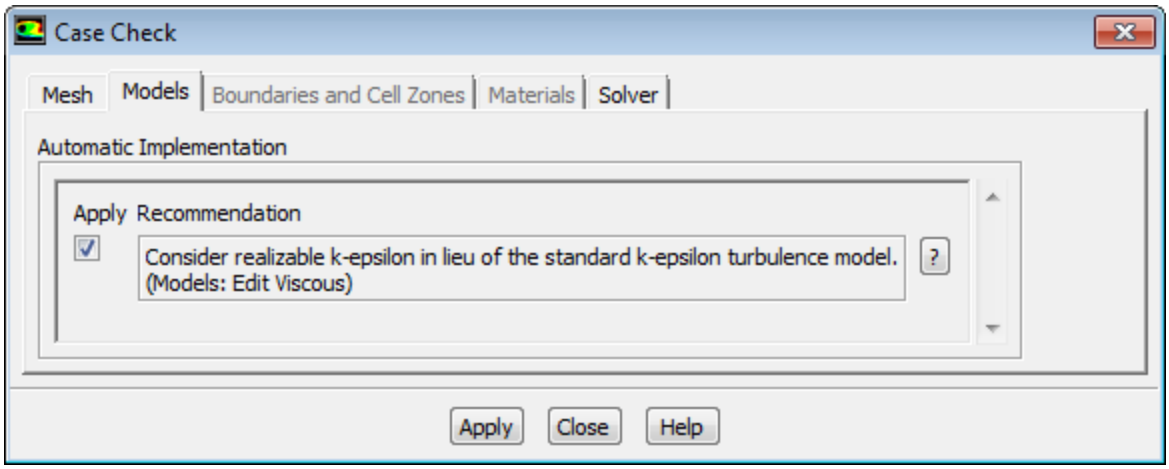
  If either **Axisymmetric** or **Axisymmetric Swirl** is specified in the **General** task page and there are mesh nodes that fall below the x-axis, then it is recommended that you translate the mesh. Nodes below the x axis are forbidden for axisymmetric cases, since the axisymmetric cell volumes are created by rotating the 2D cell volume about the x axis; therefore nodes below the x axis would create negative volumes. To find out if there are any nodes that lie below the x-axis, perform a mesh check (Checking the Mesh (p. 192)). For information on translating the mesh, see Translating the Mesh (p. 228). To access the **Mesh Translate** dialog box, go to

  Setting Up Domain → Mesh → Transform → Translate...

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.20.2.2. Checking Model Selections

Figure 28.48: The Models Tab in the Case Check Dialog Box



The following recommendations appear under the **Models** tab (Figure 28.48: The Models Tab in the Case Check Dialog Box (p. 1659)):

- **Consider realizable k-epsilon in lieu of the standard k-epsilon turbulence model.**

  The realizable k- ε model is a more recent development of the standard k- ε model and differs from it in that the realizable k- ε model contains a new formulation for the turbulent viscosity, as well as a new transport equation for the dissipation rate, ε, derived from an exact equation for the transport of the mean-square vorticity fluctuation.

  realizable k- ε model means that the model satisfies certain mathematical constraints on the Reynolds stresses, consistent with the physics of turbulent flows. For more information on the standard k-ε model and the realizable k- ε model, visit Standard k-ε Model and Realizable k-ε Model (in the Theory Guide), respectively.

  Setup → Models → Viscous → Edit...

  For information on all k- ε model options, go to Standard, RNG, and Realizable k-ε Models in the Theory Guide.

- **Disable DO/Energy coupling if the optical thickness is less than 10.**

  DO/Energy coupling should only be used when the optical thickness is greater than 10. Refer to Energy Coupling and the DO Model in the Theory Guide for more information.

  Setup → Models → Radiation → Edit...

- **Verify that the temperature specified for boundary zones that do not participate in the view factor calculation is appropriate.**

  When using the S2S radiation model, make sure that you set the temperature for boundaries that do not participate in the view factor calculation to an appropriate value. In most cases the appropriate value is the ambient temperature, which by default is assumed to be 300 K. See Specifying Boundary Zone Participation (p. 858) for more information.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Setup → Models → Radiation → Edit...

- **Change the under-relaxation factor for the mixing plane model to 1.0.**

  If you have created a mixing plane, set the **Under-Relaxation** in the **Mixing Plane** dialog box to 1. Look under Global Parameters in Setting Up the Mixing Plane Model (p. 619) for information about the mixing plane under-relaxation.

  Setting Up Domain → Mesh Models → Mixing Planes...

- **Enable the smoothing option for dynamic mesh simulations when remeshing.**

  When your case involves the use of dynamic meshes and remeshing is enabled, then it is recommended that you also perform smoothing on the mesh. For a complete discussion of smoothing and remeshing, see Setting Dynamic Mesh Modeling Parameters (p. 643).

  Setup → Dynamic Mesh → Dynamic Mesh

- **Disable species inlet diffusion for laminar flow with species transport.**

  By default, ANSYS Fluent includes the diffusion flux of species at inlets. In some cases involving species transport and laminar flow, it is recommended that the **Inlet Diffusion** option in the **Species Model** dialog box is disabled. For example,

  – If you want to include only the convective transport of species through the inlets of your domain.

  – If at one of the inlets, the convective flux is very small, resulting in mass loss by diffusion through the inlet.

  Setup → Models → Species → Edit...

  For more information about diffusion at inlets, go to Defining Cell Zone and Boundary Conditions for Species (p. 990).

- **Include turbulence interaction for the NOx model.**

  When running thermal NOx simulations and your flow is turbulent, then be sure to set the NOx **Turbulence Interaction Mode**.

  Setup → Models → NOx → Edit...

  In turbulent combustion calculations, ANSYS Fluent solves the density-weighted time-averaged Navier-Stokes equations for temperature, velocity, and species concentrations or mean mixture fraction and variance. Methods of modeling the mean turbulent reaction rate can be based on either moment methods or probability density function (PDF) techniques. ANSYS Fluent uses the PDF approach.

  To learn about how this feature is set up, go to Setting Turbulence Parameters (p. 1166).

- **Consider using the default Schnerr-Sauer or the Zwart-Gerber-Belamri cavitation model.**

  When using the mixture multiphase model with the Singhal et al. cavitation model enabled, consider changing it to either the Schnerr-Sauer or the Zwart-Gerber-Belamri cavitation model. Refer to Cavitation Models in the Theory Guide for more information.

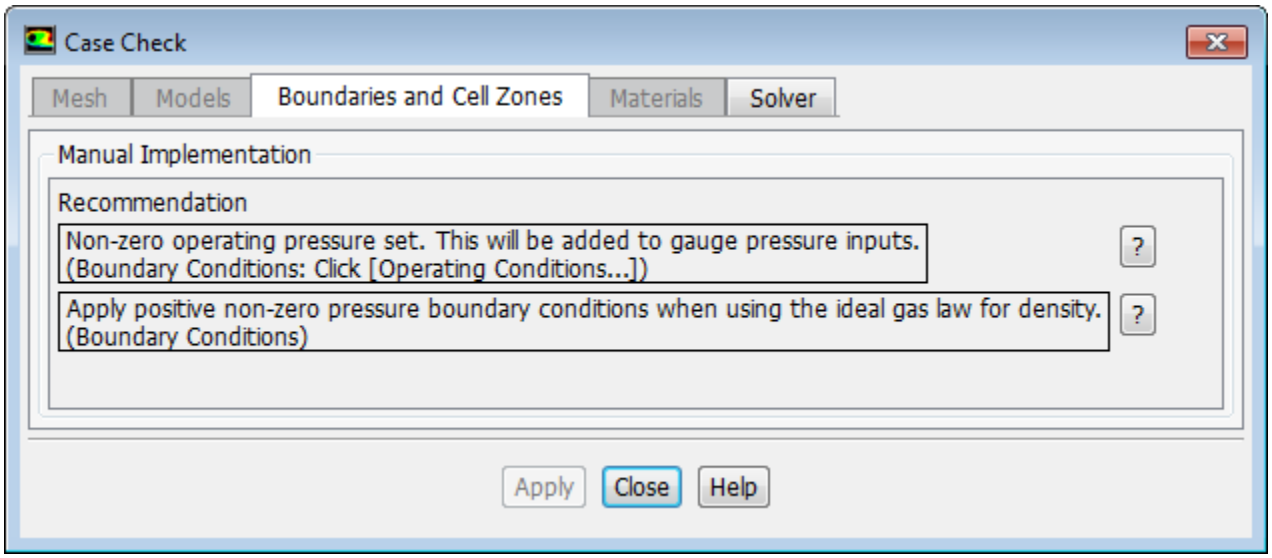
Setup → Models → Phases → Interaction...

28.20.2.3. Checking Boundary and Cell Zone Conditions

Figure 28.49: The Boundaries and Cell Zones Tab in the Case Check Dialog Box



The following recommendations appear under the **Boundaries and Cell Zones** tab (Figure 28.49: The Boundaries and Cell Zones Tab in the Case Check Dialog Box (p. 1661)):

- **Apply an axis boundary on the centerline (x-axis).**

  For geometry that is axisymmetric or axisymmetric swirl (as set in the **General** task page), the centerline (x-axis) boundary type should be set to **axis**. See Axis Boundary Conditions (p. 389).

  Boundary Conditions

- **Change outlet boundary conditions. A combination of pressure and outflow boundaries is not compatible.**

  Outflow boundary conditions in ANSYS Fluent are used to model flow exits where the details of the flow velocity and pressure are not known prior to solution of the flow problem. One of the limitations when using outflow boundary conditions is that outflow boundary conditions are not compatible with pressure inlets. Therefore, it is recommended that you use velocity or mass flow inlets instead of pressure inlets when used in combination with outflow boundaries. See Outflow Boundary Conditions (p. 350) for a list of limitations that exist with outflow boundaries.

  Setup → Boundary Conditions

- **Change outlet boundary conditions. Outflow boundary conditions are not compatible with the ideal gas law for density.**

  Outflow boundaries cannot be used if you are modeling unsteady flows with varying density, even if the flow is incompressible. See Outflow Boundary Conditions (p. 350) for more limitations that exist with outflow boundaries.

  Setup → Boundary Conditions

- **Non-zero operating pressure set. This will be added to gauge pressure inputs.**

  For cases that have density specified as the ideal gas law, and the operating pressure is greater than zero, the operating pressure will be added to the gauge pressure to yield the absolute pressure. For more information, see Density Inputs for the Ideal Gas Law for Compressible Flows (p. 485) and Operating Pressure, Gauge Pressure, and Absolute Pressure (p. 531).

  Setup → Boundary Conditions → Operating Conditions...

- **Apply positive non-zero pressure boundary conditions when using the ideal gas law for density.**

  In compressible flows , isentropic relations for an ideal gas are applied to relate total pressure, static pressure, and velocity at a pressure inlet boundary. Your input of total pressure, p_0', at the inlet and the static pressure, p_s', in the adjacent fluid cell are related, as described in Equation 6.83 (p. 316) Equation 6.84 (p. 316) of Calculation Procedure at Pressure Inlet Boundaries (p. 315). It is recommended that pressure boundary conditions are not set to zero for compressible flows that use the ideal gas law.

  Setup → Boundary Conditions

- **Review turbulence specifications at flow boundaries. Default values detected.**

  If your case setup has any of the turbulence models enabled, be sure to review the default parameters for **K and Epsilon** or **K and Omega** for the **Turbulence Specification Method** in the outlet and inlet boundary conditions. ANSYS Fluent's default parameters for the (**Backflow**) **Turbulent Kinetic Energy**, (**Backflow**) **Turbulent Dissipation Rate**, and (**Backflow**) **Specific Dissipation Rate** are 1. You can either adjust the values, or select a different **Turbulence Specification Method**. For general information turbulence parameters, see Determining Turbulence Parameters (p. 303).

  Setup → Boundary Conditions

- **Assign non-zero layer thicknesses for wall boundaries with shell conduction.**

  When the **Shell Conduction** option is enabled in the **Wall** boundary condition dialog box, ANSYS Fluent will compute heat conduction for the wall not only in the normal direction, but also in the planar directions. To enable such computations, you must specify a nonzero **Thickness** for each layer in the **Shell Conduction Layers** dialog box. See Shell Conduction (p. 376) for information on shell conduction in thin walls.

  Setup → Boundary Conditions

- **Assign a value of 0 or 1 for VOF at the inlet or outlet boundary conditions.**

  When enabling the VOF model, the **Volume Fraction** in the inlet and outlet boundary conditions for each phase should be set either to 0 or 1. No intermediate values are permitted. For general information on boundary condition setup, see Defining Multiphase Cell Zone and Boundary Conditions (p. 1391).

  Setup → Boundary Conditions

- **Change the outlet boundary condition. Outflow boundary condition is not compatible with current multiphase settings.**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

You cannot assign an outflow boundary condition when using the mixture and Eulerian multiphase models. Note the limitations of this boundary condition in Outflow Boundary Conditions (p. 350). ANSYS Fluent can model the effects of open channel flow using the VOF formulation. In such a case, outflow boundary conditions can be used at the outlet of open channel flows, to model flow exits where the details of the flow velocity and pressure are not known prior to solving the flow problem. See Open Channel Flow in the Theory Guide, under the heading Outflow Boundary, for more information.

Setup → Boundary Conditions

- **Review wall motion. Stationary wall motion relative to adjacent cell zone detected.**

  In cases where the fluid zone motion type is specified as **Moving Mesh** or **Moving Reference Frame**, all wall zones should be set to **Moving Wall** in the **Momentum** tab in the **Wall** boundary conditions dialog box. The wall motion should be defined **Relative to Adjacent Cell Zone**. The exception to this is if the walls are stationary in the absolute frame. To define wall motion, see Inputs at Wall Boundaries (p. 358).

Setup → Boundary Conditions

- **Assign non-zero velocities when specifying a moving fluid zone.**

  If selecting either **Moving Mesh** or **Moving Reference Frame** in the **Fluid** dialog box, be sure to set nonzero values for the rotational and translational velocities. Refer to Defining Zone Motion (p. 256) for user inputs.

Setup → Cell Zone Conditions

- **Review flow specifications at inlet boundaries. Default values detected.**

  For **mass-flow-inlet** and **velocity-inlet** boundary conditions, the default values in ANSYS Fluent are $1kg/s$ and $0m/s$, respectively. Review the settings and adjust accordingly. See Default Settings at Velocity Inlet Boundaries (p. 321) and Default Settings at Mass-Flow Inlet Boundaries (p. 329) for default parameters of velocity inlets and mass flow inlets, respectively.

Setup → Boundary Conditions

- **Define the porous zone when using the heat exchanger model.**

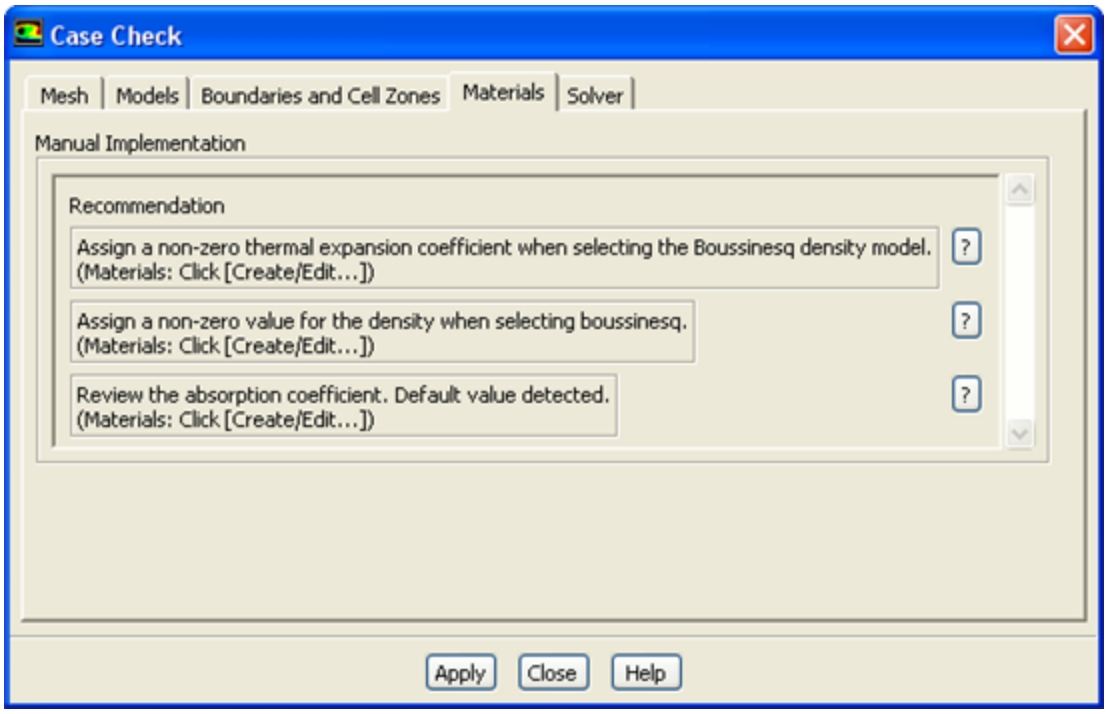
  Heat exchanger models always require the definition of the porous media zone on the primary side for the macro model and for both primary and auxiliary sides for the dual cell model. See Streamwise Pressure Drop in the Theory Guide for more information.

Setup → Cell Zone Conditions

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.20.2.4. Checking Material Properties

Figure 28.50: The Materials Tab in the Case Check Dialog Box



The following recommendations appear under the **Materials** tab (Figure 28.50: The Materials Tab in the Case Check Dialog Box (p. 1664)):

- **Assign individual fluid Cps to polynomial functions of temperature.**

  For cases with species transport and volumetric reactions, it is best practice to specify the specific heat capacity C_p as a polynomial that is a function of temperature. See Defining Properties for the Mixture and Its Constituent Species (p. 972) and Specific Heat Capacity as a Function of Temperature (p. 514) for information on defining material properties for the species in the mixture.

  Setup → **Materials**

- **Assign a non-zero value for the density when selecting boussinesq.**

  The Boussinesq model is used for natural convection problems involving small changes in temperature. To enable the Boussinesq approximation for density, choose **boussinesq** from the **Density** drop-down list in the **Create/Edit Materials** dialog box and specify a constant value for **Density**. See Inputs for the Boussinesq Approximation (p. 480).

  Setup → **Materials**

- **Review the absorption coefficient. Default value detected.**

  If any of the radiation models are enabled. Enter an absorption coefficient for the material listed (Radiation Properties (p. 515)).

  Setup → **Materials**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

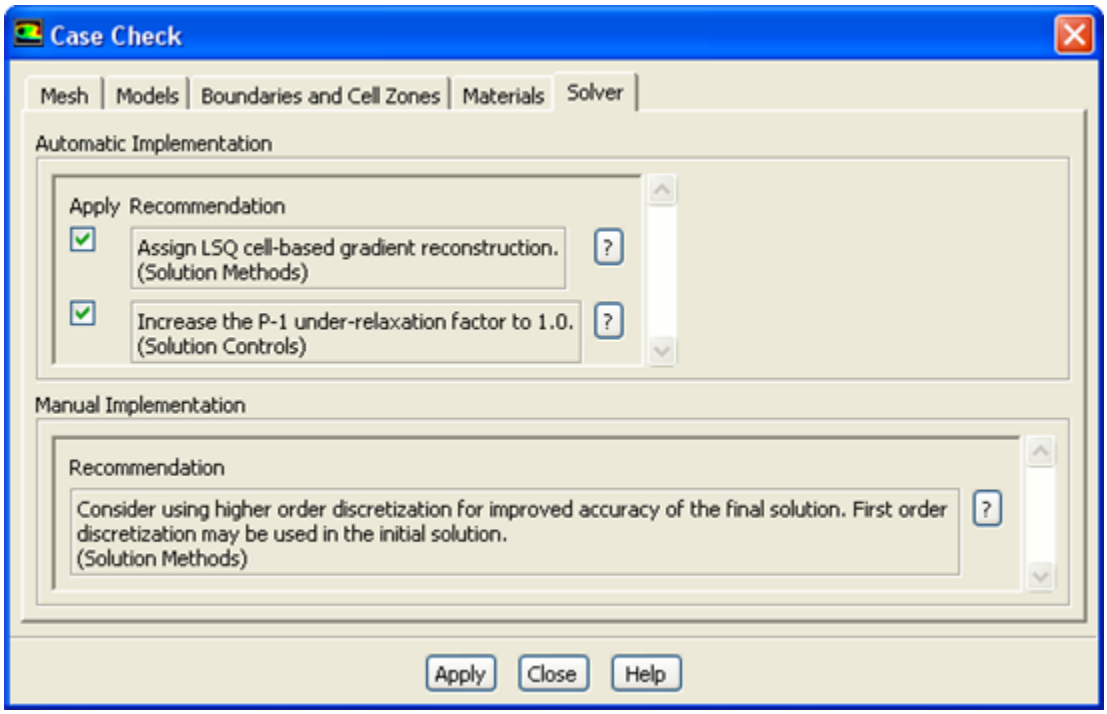
- **Assign a non-zero thermal expansion coefficient when selecting the Boussinesq density model.**

  When selecting **boussinesq** to describe the density of your material, be sure to enter a valid thermal expansion coefficient for your material. For detailed information on the Boussinesq model, see The Boussinesq Model (p. 833).

  Setup → Materials

28.20.2.5. Checking the Solver Settings

Figure 28.51: The Solver Tab in the Case Check Dialog Box



The following recommendations appear under the **Solver** tab (Figure 28.51: The Solver Tab in the Case Check Dialog Box (p. 1665)):

- **Enable the unsteady solver option when selecting moving mesh for the fluid boundary.**

  If the motion type of the fluid boundary condition is specified as **Moving Mesh**, then your case should be specified as **Transient** in the **General** task page. Visit Setting Up the Sliding Mesh Problem (p. 634) for steps on setting up moving mesh problem.

  Setup → General

- **Assign LSQ cell-based gradient reconstruction.**

  The least squares cell-based averaging scheme is known to be as accurate as the node-based gradient for irregular unstructured meshes, but less expensive to compute than the node-based gradient. Therefore, it is recommended that least squares cell-based gradient reconstruction is used. See Evaluation of Gradients and Derivatives in the Theory Guide for more information on gradient options.

  Solution → Methods

- **Change the under-relaxation factor for the energy equation to at least 0.90.**

  You should set the energy under-relaxation factor between 0.90 and 1.0. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the energy under-relaxation factor to `0.90`. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See Solution Strategies for Heat Transfer Modeling (p. 828) for the under-relaxation of the energy equation.

  Solution → **Controls**

- **Increase the NOx under-relaxation factor to at least 0.90.**

  If the NOx model is enabled, set the NOx under-relaxation factor to a value of at least 0.90 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the NOx under-relaxation factor to `0.90`. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See Using the NOx Model (p. 1153).

  Solution → **Controls**

- **Increase the Discrete Ordinates under-relaxation factor to at least 0.90.**

  If the Discrete Ordinates (DO) radiation model is enabled, set the radiation under-relaxation factor to a value of at least 0.90 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the radiation under-relaxation factor to `0.90`. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See DO Solution Parameters (p. 880).

  Solution → **Controls**

- **Increase the P1 under-relaxation factor to 1.0.**

  If the P1 radiation model is enabled, set the radiation under-relaxation factor to 1.0 to fully converge the solution. Note that the under-relaxation factor could be lower at the start of the run, but can then be increased after an initial solution is obtained. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the radiation under-relaxation factor to `1.0`. See P-1 Model Solution Parameters (p. 878).

  Solution → **Controls**

- **Increase the species and energy under-relaxation factors to at least 0.90.**

  For a case with species transport and energy defined, set the species and energy under-relaxation factors to a value of at least 0.90. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the species and energy under-relaxation factors to `0.90`. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See Solution Procedures for Chemical Mixing and Finite-Rate Chemistry (p. 990).

  Solution → **Controls**

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

- **Assign a value of 1 for the under-relaxation factor for unsteady DPM with 1 DPM update per time step.**

  It is recommended that the DPM under-relaxation factor be set to 1 for unsteady DPM with 1 DPM update per time step.

  Solution → **Controls**

- **Increase the mean mixture fraction under-relaxation factor to at least 0.90.**

  If the non-premixed or partially premixed combustion models are enabled, then it is best to set the mean mixture under-relaxation factor to a value of at least 0.90 to ensure full convergence. If you decide to apply this recommendation, then ANSYS Fluent will automatically set the mean mixture under-relaxation factor to `0.90`. If you want to increase this value, you can manually make the change by going to the **Solution Controls** task page. See Solving the Flow Problem (p. 1083).

  Solution → **Controls**

- **Consider using higher order discretization for improved accuracy of the final solution. First-order discretization may be used in the initial solution.**

  It is generally advisable to obtain an initial solution using first-order accurate discretization, however, second order discretization is recommended for improved accuracy of the final solution. See Choosing the Spatial Discretization Scheme (p. 1554) for more information on discretization schemes.

  Solution → **Methods**

- **Select the absolute reference frame for initializing cases when using the MRF model.**

  When using the MRF model, always use the absolute reference frame while initializing the solution. Select **Absolute** under **Reference Frame** in the **Solution Initialization** task page. If the **Relative to Cell Zone** option is selected, which is the default option, the initial flow field can contain discontinuities, which can cause convergence problems in the first few iterations. Refer to Initializing the Entire Flow Field Using Standard Initialization (p. 1591) for more information.

  Solution → **Initialization** **Initialize**

- **Choose PRESTO! for the pressure discretization scheme.**

  When using the VOF model, it is recommended that you use **PRESTO!** as the pressure discretization scheme. This scheme is recommended for flows with high swirl numbers, a high-Rayleigh-number natural convection, high-speed rotating flows, flows involving porous media, and flows in strongly curved domains. See Choosing the Pressure Interpolation Scheme (p. 1556) for more information.

  Solution → **Methods**

28.21. Convergence and Stability

Convergence can be hindered by a number of factors. Large numbers of computational cells, overly conservative under-relaxation factors, and complex flow physics are often the main causes. Sometimes it is difficult to know whether you have a converged solution. In the following sections, some of the

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

numerical controls and modeling techniques that can be exercised to enhance convergence and maintain stability are examined.

28.21.1. Judging Convergence
28.21.2. Step-by-Step Solution Processes
28.21.3. Modifying Algebraic Multigrid Parameters
28.21.4. Modifying the Multi-Stage Parameters
28.21.5. Robustness on Meshes of Poor Quality
28.21.6. Warped-Face Gradient Correction

You should also refer to Choosing the Spatial Discretization Scheme (p. 1554) and Choosing the Pressure-Velocity Coupling Method (p. 1561) for information about how the choice of discretization scheme or (for the pressure-based solver) pressure-velocity coupling scheme can affect convergence. Manipulation of under-relaxation parameters and multigrid settings to enhance convergence is discussed in Setting Under-Relaxation Factors (p. 1564) and Modifying Algebraic Multigrid Parameters (p. 1670).

28.21.1. Judging Convergence

There are no universal metrics for judging convergence. Residual definitions that are useful for one class of problem are sometimes misleading for other classes of problems. Therefore it is a good idea to judge convergence not only by examining residual levels, but also by monitoring relevant integrated quantities such as drag or heat transfer coefficient.

For most problems, the default convergence criterion in ANSYS Fluent is sufficient. This criterion requires that the globally scaled residuals, defined by Equation 28.6 (p. 1625) or Equation 28.12 (p. 1626) decrease to 10^{-3} for all equations except the energy and P-1 equations, for which the criterion is 10^{-6}. Locally scaled residuals defined by Equation 28.7 (p. 1625) or Equation 28.13 (p. 1626) decrease to 10^{-5} for all equations.

Sometimes, however, this criterion may not be appropriate. Typical situations are listed below.

- If you make a good initial guess of the flow field, the initial continuity residual may be very small leading to a large scaled residual for the continuity equation. In such a situation it is useful to examine the unscaled residual and compare it with an appropriate scale, such as the mass flow rate at the inlet.

- For some equations, such as for turbulence quantities, a poor initial guess may result in high scale factors. In such cases, scaled residuals will start low, increase as nonlinear sources build up, and eventually decrease. It is therefore good practice to judge convergence not just from the value of the residual itself, but from its behavior. You should ensure that the residual continues to decrease (or remain low) for several iterations (say 50 or more) before concluding that the solution has converged.

Another popular approach to judging convergence is to require that the unscaled residuals drop by three orders of magnitude. ANSYS Fluent provides residual normalization for this purpose, as discussed in Definition of Residuals for the Pressure-Based Solver (p. 1624), where residuals are defined for both the pressure-based solver and the density-based solver. In this approach the convergence criterion is that the normalized unscaled residuals should drop to 10^{-3}. However, this requirement may not be appropriate in many cases:

- If you have provided a very good initial guess, the residuals may not drop three orders of magnitude. In a nearly-isothermal flow, for example, energy residuals may not drop three orders if the initial guess of temperature is very close to the final solution.

- If the governing equation contains nonlinear source terms which are zero at the beginning of the calculation and build up slowly during computation, the residuals may not drop three orders of magnitude. In the case

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

of natural convection in an enclosure, for example, initial momentum residuals may be very close to zero because the initial uniform temperature guess does not generate buoyancy. In such a case, the initial nearly-zero residual is not a good scale for the residual.

- If the variable of interest is nearly zero everywhere, the residuals may not drop three orders of magnitude. In fully-developed flow in a pipe, for example, the cross-sectional velocities are zero. If these velocities have been initialized to zero, initial (and final) residuals are both close to zero, and a three-order drop cannot be expected.

In such cases, it is wise to monitor integrated quantities, such as drag or overall heat transfer coefficient, before concluding that the solution has converged. It may also be useful to examine the un-normalized unscaled residual, and determine if the residual is small compared to some appropriate scale. Alternatively, the scaled residual defined by Equation 28.6 (p. 1625) or Equation 28.12 (p. 1626) (the default) may be considered.

Conversely, it is possible that if the initial guess is very bad, the initial residuals are so large that a three-order drop in residual does not guarantee convergence. This is specially true for k and ε equations where good initial guesses are difficult. Here again it is useful to examine overall integrated quantities that you are particularly interested in. If the solution is unconverged, you may drop the convergence tolerance, as described in Modifying Convergence Criteria (p. 1631).

28.21.2. Step-by-Step Solution Processes

One important technique for speeding convergence for complex problems is to tackle the problem one step at a time. When modeling a problem with heat transfer, you can begin with the calculation of the isothermal flow. To solve turbulent flow, you might start with the calculation of laminar flow. When modeling a reacting flow, you can begin by computing a partially converged solution to the non-reacting flow, possibly including the species mixing. When modeling a discrete phase, such as fuel evaporating from droplets, it is a good idea to solve the gas-phase flow field first. Such solutions generally serve as a good starting point for the calculation of the more complex problems. These step-by-step techniques involve using the Solution Controls Task Page (p. 2508) to turn equations on and off in the **Equations** dialog box.

28.21.2.1. Selecting a Subset of the Solution Equations

ANSYS Fluent automatically solves each equation that is turned on using the **Models** family of dialog boxes. If you specify in the Viscous Model Dialog Box (p. 2176) that the flow is turbulent, equations for conservation of turbulence quantities are turned on. If you specify in the Energy Dialog Box (p. 2175) that ANSYS Fluent should enable energy, the energy equation is enabled. Convergence can be sped up by focusing the computational effort on the equations of primary importance. The **Equations** list in the Equations Dialog Box (p. 2511) allows you to turn individual equations on or off temporarily.

Solution → **Controls** → **Equations...**

A typical example is the computation of a flow with heat transfer. Initially, you will define the full problem scope, including the thermal boundary conditions and temperature-dependent flow properties. Following the problem setup, you will use the **Equations** dialog box to temporarily turn off the energy

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

equation. You can then compute an isothermal flow field, remembering to set a reasonable initial value for the temperature of the fluid.

Important

This is possible only for the pressure-based solver; the density-based solver solves the energy equation together with the flow equations in a coupled manner, so you cannot turn off the energy equation as described above.

When the isothermal flow is reasonably well converged, you can turn the energy equation back on. You can actually turn off the momentum and continuity equations while the initial energy field is being computed. When the energy field begins to converge well, you can turn the momentum and continuity equations back on so that the flow pattern can adjust to the new temperature field. The temperature will couple back into the flow solution by its impact on fluid properties such as density and viscosity. The temperature field will have no effect on the flow field if the fluid properties (for example, density, viscosity) do not vary with temperature. In such cases, you can compute the energy field without turning the flow equations back on again.

Important

If you have specified temperature-dependent flow properties, you should be sure that a realistic value has been set for temperature throughout the domain before disabling calculation of the energy equation. If an unrealistic temperature value is used, the flow properties dependent on temperature will also be unrealistic, and the flow field will be adversely affected. Instructions for initializing the temperature field or patching a temperature field onto an existing solution are provided in Initializing the Solution (p. 1591).

28.21.2.2. Turning Reactions On and Off

To solve a species mixing problem prior to solving a reacting flow, you should set up the problem including all of the reaction information, and save the complete case file. To turn off the reaction so that only the species mixing problem can be solved, you can use the Species Model Dialog Box (p. 2216) to turn off the **Volumetric** option under **Reactions**.

Setup → **Models** → **Species** → **Edit...**

Once the species mixing problem has partially converged, you can return to the **Species Model** dialog box and turn the **Volumetric Reactions** option on again. You can then resume the calculation starting from the partially converged data.

For combustion problems you may want to patch a hot temperature in the vicinity of the anticipated reactions before you restart the calculation. See Patching Values in Selected Cells (p. 1593) for information about patching an initial value for a flow variable.

28.21.3. Modifying Algebraic Multigrid Parameters

The default algebraic multigrid settings are appropriate for nearly all problems, but in rare cases you may need to make minor adjustments. Setting Algebraic Multigrid Parameters (p. 1577) describes how to analyze the multigrid solver's performance to determine which parameters.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

28.21.4. Modifying the Multi-Stage Parameters

It is possible to make several changes to the multi-stage time-stepping scheme itself. See Changing the Multi-Stage Scheme (p. 1588) for detailed information.

28.21.5. Robustness on Meshes of Poor Quality

Poor quality meshes are meshes containing highly skewed cells, highly non-orthogonal cells, non-convex cells, or cells with left-handed faces. Such mesh elements tend to decrease the numerical stability of traditional CFD discretization algorithms. These mesh elements require special treatment, namely, a numerical correction of the transport equation discretization, which is intended to improve the numerical properties of the solution algorithms at mesh cells of poor quality.

Note

If your mesh exhibits any type of poor quality except left-handed faces, you can maintain second order accuracy by using the warped-face gradient correction and disabling poor mesh numerics. To disable poor mesh numerics, set `solve/set/poor-mesh-numerics/enable?` to `no`. For additional information on this method, see Warped-Face Gradient Correction (p. 1674).

In order to facilitate solution convergence on meshes of poor quality, the ANSYS Fluent solver can apply a local solution correction, limited spatially to distorted cells of the mesh. If you read in a poor quality mesh containing cells and faces with corrupt metrics, you will see a warning in the TUI of the form:

```
Info: The mesh contains elements that are invalid or of poor quality.

      A different numerical scheme will be applied to these elements,
      which may affect the quality of the solution. It is recommended
      that you consider removing the invalid and poor quality elements
      in the mesh.

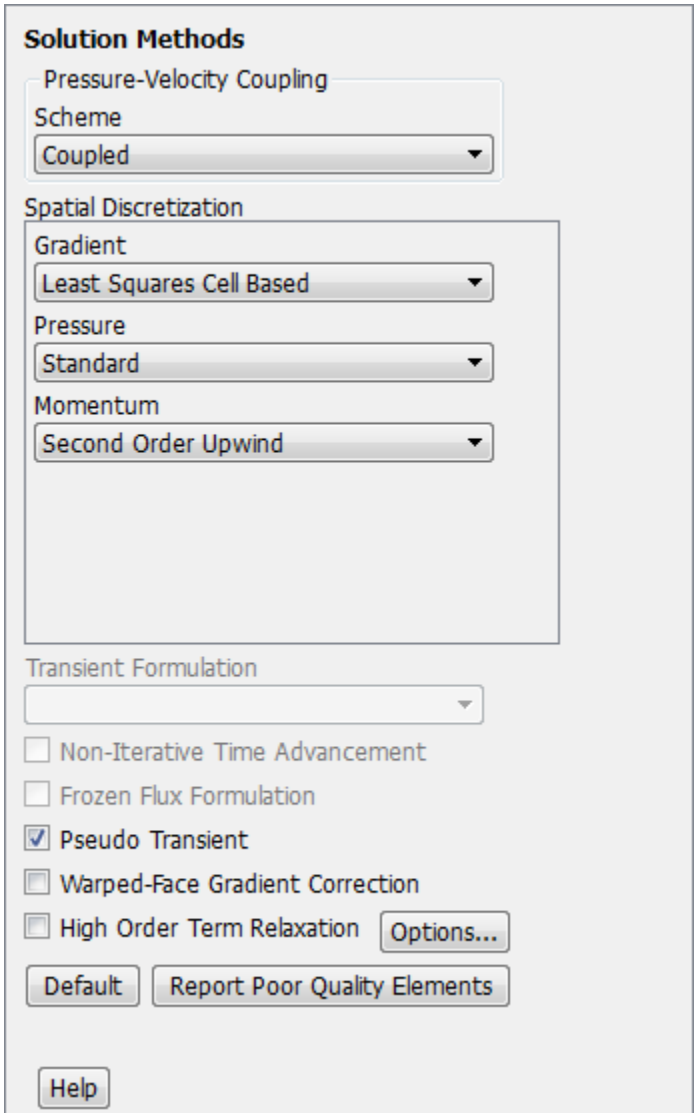
      For more information on the invalid and poor quality elements,
      please use the following TUI commands:

      /mesh/check
      /mesh/repair-improve/report-poor-elements.
```

Additionally, in the **Solution Methods** task page, the **Report Poor Quality Elements** button will appear, which can be used to report more statistics on the number and type of cells that ANSYS Fluent has identified as having poor quality (see Figure 28.52: Reporting Poor Quality Elements (p. 1672)).

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

Figure 28.52: Reporting Poor Quality Elements



In order to facilitate solution convergence on meshes of poor quality, the ANSYS Fluent solver can apply a local solution correction, limited spatially to distorted cells of the mesh. The corrected solution can be of 0th, 1st, or 2nd order:

- The 0th order scheme applies an algorithm that computes the solution variable for the transport equation in the bad cells by assembling the solution directly from the surrounding solution in the better quality cells.
- The 1st order scheme applies locally low order discretization methods and neglects some non-orthogonal contributions to the gradients when computing the diffusive fluxes.
- The 2nd order scheme only modifies the numerics in the bad cells by assembling the gradient vector for the given solution variable from the gradients in the surrounding better quality cells.

In other words, the discretization error will be independent of the mesh size in this region if 0th order is used. It will decrease linearly with subsequent grid refinement when 1st order is used, and quadratically when the 2nd order option is selected.

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

By default, Fluent will apply the 1st order correction scheme to any invalid cells. Using text commands, you can further control the application of the poor mesh numerics by using one of the other schemes, including highly skewed and highly non-orthogonal cells, and including cells from a user-defined register. The text commands that are available are as follows:

/solve/set/poor-mesh-numerics/enable?

Choose whether or not to apply the poor mesh numerics corrections and specify which order scheme to use.

In general, it is recommended that you use the 1st order solution correction, which provides a reasonable compromise between accuracy and stability gain. For meshes of better (and yet still low) quality it is advisable to try the 2nd order option, which will preserve the mesh convergence behavior provided by the convection term discretization schemes. In case no convergence is obtained with any of the aforementioned schemes, you should use the 0th order option, which will provide the highest stability and at the same time the lowest accuracy. In regions with highly nonlinear flow physics this scheme can yield highly nonphysical results.

The computational time (or cost or run time requirements) for all three schemes will increase linearly as the number of cells identified as poor quality cells increases. Provided that there is reasonable convergence behavior with all three schemes, the 1st order option will be the fastest; 0th and 2nd order schemes will have similar run times to each other.

/solve/set/poor-mesh-numerics/cell-quality-based?

Choose whether or not the poor mesh numerics should also be applied to cells that are highly non-orthogonal or highly skewed.

/solve/set/poor-mesh-numerics/set-quality-threshold

Set the threshold for including cells based on cell quality metrics when `cell-quality-based?` is enabled. The value you enter is applied as a threshold for the cell orthogonality and the complement of cell skewness below which the poor mesh numerics will be applied. The default value is `0.05`. Some cases may require tuning this parameter to improve stability.

/solve/set/poor-mesh-numerics/user-defined-on-register

Answer **yes** at the prompt to Include cells from a register in the poor mesh numerics treatment. You will be prompted for the name or ID of the register to include. Note that if you answer **no** at the prompt any cells previously included from registers are removed from the list of cells for poor mesh numerics.

If you include a user-defined register in the poor mesh numerics, reporting of poor mesh element statistics will also include the cells added by the `user-defined-on-register` command. For example:

```
Poor Mesh Element Statistics:
Identified    0 faces with too small area.
Identified    0 faces adjacent to negative volume cells.
```

Release 18.1 - © ANSYS, Inc. All rights reserved. - Contains proprietary and confidential information of ANSYS, Inc. and its subsidiaries and affiliates.

```
Identified    0 faces adjacent to bad quality cells.
Identified   43 cells from user-defined register.
```

Note

The statistics not only report the cells included in the register, but also their neighboring cells, resulting in an overall larger number of cells being identified.

Important

It is your responsibility to maintain the register-based cells. If you change the mesh, (for example, using mesh manipulation, adaptation, and so on), then you must use the `user-defined-on-register` command again. Enter `yes` to the command prompt in order to update the cells based on a new register, otherwise, enter `no` to remove all cells from the poor mesh numerics list. For more information about registers, see Registers (p. 1700).

`/solve/set/poor-mesh-numerics/print-poor-elements-count`

Print out a listing of the poor cells for each criterion (default, cell quality, and user-defined).

```
